On the cover: The photo shows the QTH of Dick Sparling N2KEY on Chautauqua Lake, Bemus Point, NY.

Feedback: Any circuit works better with feedback, so please take the time to report on how much you like, hate, or don't care one way or the other about the articles and columns in this issue. G = great!, O = okay, and U = ugh. The G's and O's will be continued. Enough U's and it's Silent Keysville. Hey, this is *your* communications medium, so don't just sit there scratching your...er...head. FYI: Feedback "number" is the page number on which the article or column starts as shown in the index.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by 73 Magazine, 70 N202, Peterborough NH 03458-1107.

The subscription rate is: one year $24.97, two years $44.97; Canada: one year $34.21, two years $57.75, including postage and 7% GST. Foreign postage: $19 surface, $42 airmail additional per year, payable in US funds on a US bank. Second class postage is paid at Peterborough, NH, and at additional mailing offices. Canadian second class mail registration #178101. Canadian GST registration #125393314. Microfilm edition: University Microfilm, Ann Arbor MI 48106. POSTMASTER: Send address changes to *73 Amateir Radio Today*, 70 N202, Peterborough NH 03458-1107.

Contract: Merely exposing this page to your eyeballs consititutes a llegally binding contract between you and publiisher Green wherein you have agreed to get out of that rut you've been in, to shape up and put some adventure into your life. Thus you will, in 1996, open at least one new ham horizon, such as getting active on packet or get set up and start making satellite contacts. Further, you will document this adventure with a log and send a copy to publisher Green, and give a talk on your adventure to your local ham club, plus write a piece for the ham club newsletter.

NEVER SAY DIE

Wayne Green W2NSD/1

Sunny Surprise

Astronomers at the California Institute of Technology have reported the first sunspot of the new cycle. Pause a moment for a round of cheers. They were surprised at the early start for Cycle 23. It's expected to peak around 1998, since the spots tend to build up rapidly and then fade away more slowly.

It'll be nice to have the HF bands open around the world again, and to be able to make contacts all night on 20m. During the better sunspot peaks even 6m opens up, allowing worldwide communications with low power. I remember one day when I tuned 6m with my pre-war Meissner FM tuner and heard the sixes and sevens boiling through. That sent me right to my workbench to build a 6m transmitter. Well, to convert a surplus SCR-522 rig to six.

Maybe you didn't know that the pre-war FM broadcast band went from 50-56 MHz, with us hams on five meters, 56-60 MHz. The two-and-a-half meter ham band went from 112-116 MHz. Well, mc, actually, since hertz hadn't been invented yet as a replacement for cycles per second. The SD radar on my submarine was on 112 mc, so I felt right at home. The main problem with that was that the Japanese quickly installed 112-MHz receivers in their planes so they could home in on our radar. That tended to discourage us from using it other than for an occasional quick blast.

The SJ radar, which was mainly for surface work, was up at 3,000 MHz, where the Japanese apparently hadn't figured out how to build receivers. So I used the SJ for spotting both ships and planes, and kept the SD off most of the time.

Back in 1949, I was one of the six meter pioneers. I was the only one on six in New York City. We were all crystal-controlled in those days, so I could tell the call letters of any signal, just by measuring its frequency with my surplus General Radio LR-1 frequency meter. Big sucker, with nearly a hundred tubes.

I got a 50.1-MHz crystal and set up a beacon so hams out West or in Europe would know when the band was open to my area. I made a code wheel out of aluminum, operating a microswitch to key the rig.

As the new sunspot cycle builds we're going to see DX coming back, so it's time to start planning your dream location, dream tower, dream beam and state-of-the-art ham station for late 1996. I've got the location, but I need some help in deciding what I should use for antennas.

In retrospect I can almost feel the angel wings brushing me when I tuned 6m and heard the pandemonium from out West. That got me on the air on six. And that got me to put on my beacon station. Then, along came Perry Ferrell with an Air Force contract to study 50-MHz propagation, so I helped him with my reception reports, plus the reception reports of my beacon. This was the Radio Amateur Scientific Observation project, RASO.

Perry awarded me a certificate for helping the project. Then, a couple years later, he became the editor of *CQ*. By then I was deep into RTTY. Perry liked my *Amateur Radio Frontiers* magazine and asked me to do a RTTY column for *CQ*. That helped generate more interest in RTTY, but more important, I got to be good friends with Perry, and knew he hated *CQ* publisher Sandy Cowan. So I helped Perry get the editor's job at *Popular Electronics*, since I knew the publishers, Bill Stocklin and Ollie Read. That led to me becoming the *CQ* editor, which I hadn't even considered before. Serendipity.

Adopt-A-Ham

I was reading in the Dayton club newsletter about the program set up by the Upper Valley Radio Club with Beavercreek's Brookwood Elementary School. They lined up four 9- and 10-year-old students to talk over the local repeater to each of seven club members. The aim wasn't primarily to get them interested in hamming, but rather to help the kids develop their ability to talk with people. That's called oral skills these days. However, two of the kids did get their tickets, and many previously inarticulate kids learned to talk freely with total strangers over the air.

Antenna Pruning

An article by W3HVS in the Port St. Lucie club newsletter reminded me that it's been years since I passed along a simple antenna pruning system. You can cut a half-wave dipole wire antenna exactly to the frequency you want with just one prune, if you do it right.

You start out with the half-wave formula of 468 divided by the frequency in MHz for the length in feet. Add on a foot or so, just in case. It's a lot easier to trim off a few inches than to add it if you come up short. The problem is that the length of your antenna depends to some degree on its height above ground, and how good the ground is under it.

Make it a little long and put it up into place. Now check for its resonant frequency. An antenna bridge is great here, but you can also just check for the frequency providing the lowest SWR. Now you can use a simple proportion of the length and the resulting resonant frequency to the desired frequency and the new length. Trim half of the difference off each end and you'll be all set.

You won't do a lot on 20m with a dipole, though my first sideband contact was with a 10-watt exciter and a twin-lead dipole thrown out of my window. I worked a VK and had a nice contact.

On 75m I've worked the world with a dipole. Everywhere. At the time I had a corking signal on 20m, but with the Sweepstakes Contest coming up the next day I knew I would have to have some 75m contacts during the hours when 20 was quiet, so I cut a twin-lead dipole and hung it slanted from my tower. The result was a whopping signal on 75, and contacts all the way out to Okinawa.

When I was visiting VK3ATN in Australia we worked W2NSD/1 on 20m. My signal was coming in S9+, so we decided to try 75 and see if we could make it. It was S9+ there too! I still haven't gotten over the excitement of that contact. Never will.

Pirate FM

Recently I wrote about a possible business opportunity for hams in setting up low-powered FM transmitters for private parties who'd like to be able to listen to their own music around their home. A chap in Berkeley has been carrying this to extremes with his Free Radio Berkeley (FRB). Steve Dunifer started out with a 5-watt rig and a 10-foot antenna, broadcasting three hours Sunday nights on an unused FM channel. The FCC naturally got after him, assessing him a $20,000 fine. Dunifer fought back with lawyers, demanding to get copies of the reports of interference, which the FCC had cited in their complaint.

When the FCC could produce nothing, Dunifer began making and selling micro-power FM transmitting kits, with the result that several hundred similar stations are now in operation around the country. Then, when a federal judge refused to back the FCC on constitutional grounds, he took FRB full-time from a permanent location, broadcasting 24 hours a day, complete with a call-in phone number and running about 40 watts.

Canada allows unlicensed micropower FM stations, but monitors them to make sure they don't interfere with commercial stations. And in Japan unlicensed FM stations with up to 10 watts are permitted, with community stations popping up all over the country. Companies such as Teac and Sony are selling micropower FM station kits which include everything needed, even a CD player.

Brazilian Licenses

A note from PU2MPP explains that they have three license classes in Brazil. Class C requires no code. Class B requires 5 wpm code. Class A is 10 wpm. To be more detailed, the Class B test sends 125 characters in five minutes and calls for a minimum of 87 characters to be copied correctly. The Class A is double that. That sure beats our 20 wpm hurdle.

If You're So Smart...

Okay, as a ham you are a communications expert. Well, you're supposed to be. That's what you've conned your non-ham friends into thinking, right?

So what do you really know about communications, other than kerchunking some repeaters or adding still more garble to a pileup? If someone were to ask you about pagers, what could you tell them? How much do they cost? What's their range? Where do you get 'em? What frequencies do they use? What services are available? Can you use some just around your own business?

And what can you tell people about fax-modems? The Internet,

LETTERS

Number 6 on your Feedback card

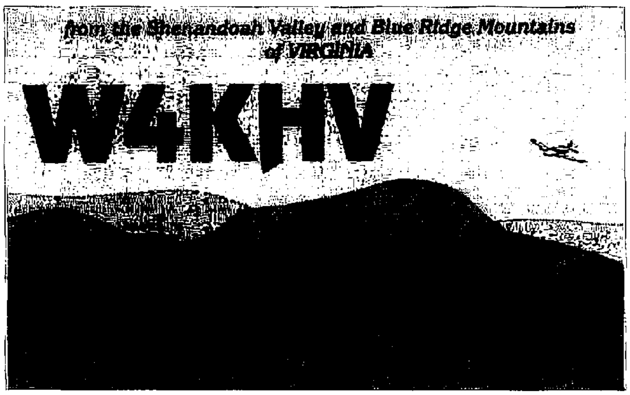
From the Ham Shack

Dick Smith W4KHV Over the years I have enjoyed your columns and find them not only enlightening but thought-provoking. While I have not always agreed with all you have said (does anyone always agree with everything one says?), I do find myself siding with your thoughts most of the time. Superfluous for me to say, keep it up, as I know you will. Thanks. After reading your November editorial I would like to comment on a number of subjects you touched on. First, you asked for letters about most recent building projects, etc. Well, I do build small electronic projects now and then for my other main hobby, RC model planes. I have been in model planes since I was a kid and RC planes since 1949. I have been a licensed ham since 1953 (W1ZVG). However, I do not build much ham equipment now, other than a QRP rig this past year. My antenna will have to be improved before it's a real success. I still build quite a few planes, with my largest being a 9' (wing span) replica of a WWI Sopwith "Pup" biplane. This is an RC plane which is 1/3 scale. I fly on both 6 meters and 72 MHz. Radio "contests" do not move me, nor do nets. About 80% of my hamming is on 40 CW, and I enjoy it. Yes, I know CW is dead to many, antique, etc., and not promoted by people such as youself. But still, it's fun—isn't this what this hobby should be? And yes, the other side of the coin is to develop new ideas, techniques, invent, and pioneer. This where your insight is so valuable to those technically capable. I also participate on a local level in various community projects, including ARES and Skywarn. Your November column was one of your better info columns. In fact, I asked my wife to read it from start to finish (she did). It was the first time she has ever read anything from a "ham" magazine. She was really taken by your observations about the Government cover-ups, roadblocks to cures, health, etc. I'm sure she'll be reading your future colums too. We tried your old recipe for coleslaw. It was very good and we'll be using it again, but with a little less vinegar. Then we'll have a good comparison to make against our favorite recipe. Thanks for giving it out. We both try for low fat foods (and high fiber) so will be giving it try with the low/non- fat ingredients.

Although not a ham as long as you Wayne (I'm 65), I have had a number of honors as result a of being a ham. My highest one was when I lived in the Phoenix area back in late '60s and became one of Barry Goldwater's MARS operators. I ran phone patches from his home to servicemen in the Pacific and Southeast Asia. To this day I don't believe the public, or hams, really know what a contribution he made to the morale of our servicemen in those areas. When I was out there he had two complete stations, one was Collins equipment capable of running 4kW, and one with Drake equipment running 2kW. Aside from spending some long evenings after a day's work, it was fun and most satisfying from a personal standpoint. It's still a great memory.

You can adjust the sourness of the coleslaw dressing by adding more sugar or honey. It's also a fabulous dip for raw veggies. Cheaper than the bottled dressing, too . . . Wayne

Michael D. Zandee AA8QL Gee whiz Wayne, we better keep the code requirement and six license classes, or we won't have anything at all to discuss on the air. Here's my two cents on Mr. Weinhold N3EUL's letter. I'm sure you *can* tell the new no-coders, but not for long. They either conform or the old heads run them off. Then Mr. Goodman W3UWH's call for a senior upgrade: If they want it bad enough they would find a way. It's too bad your friends won't even try. I went from no ticket at all to Extra in four months and found it felt like cheating. It was so easy I didn't get the sense of accomplishment that should have been there.



Richard Heppert KC4YQL In the October issue there was an interesting article by a ham who had finally pushed himself to get his Extra after 46 years. He was now finding it rewarding to work testing sessions and Elmer others through the upgrade process. Bravo! But he was also finding too many of his fellow longtime operators were reluctant to attempt to upgrade because, although they could handle the code speed, they felt they could not learn the necessary math. He proposed creating a special upgrade license for these old-timers as a reward for their many years of "service," and requested feedback on the idea. I had to check to be sure that it wasn't the April issue. This past weekend I participated in a discussion at a local hamfest that worked its way around to the code requirement. It was the opinion of one fellow (my guess is he was 50ish) that he would rather see the FCC drop written tests altogether than see an elimination of the higher speed code requirements—after all, "nobody builds or repairs anything anymore so the tests are irrelevant." The "logic" of the two proposals eludes me—or just maybe I see it too well: Screw any relevant technical knowledge, theory, and regulations, and give higher licenses to those who have nothing better to do than practice the oldest form of communication known to hams—CW. As for the first proposal, the satisfaction of having performed service, had it actually been performed, should have been its own reward. Had these old-timers grown and progressed with the hobby's technology they would have had little trouble passing the technical tests, or at least been less scared to try. As for the proposal to eliminate written tests about regulations, procedure, propagation, antenna theory, safety, band plans, and modes, not to mention basic electronic theory, but keeping CW, this is a blatant cry for elitist "I did it—they should too" mentality. If CW is so important, I'd like to propose re-testing every five years on written and code. If you don't pass you're busted back to Novice and have to work your way back up. Do we see a few quaking in their boots at that thought? Seriously, the FCC tests for each license class should change/grow with the technical advancement of the amateur radio "service," and for a large part they have. The major exception has been the Elements 1B and 1C CW requirements (1A is still necessary to meet ITU regulations). The only way we are going to keep our bands is to recruit, encourage and reward the innovators, not reward hams for merely existing and not causing trouble. Extra privileges and band space should go to the people willing to use and explore newer technologies: after all, from the beginning that is the major reason we were allocated our bands. If any testing changes are made they should start with the elimination of the 1B and 1C elements, with further emphasis placed on today's and tomorrow's technologies, not yesterday's. Grow, or die.

When hundreds of ham clubs, under pressure from the ARRL, wrote to the FCC claiming that the Morse code was of enormous importance for its potential use in emergencies, I said, if you honestly believe what you testified to the FCC, then we obviously should require code tests for every license renewal. Oh, the frenzied screams of anguish that raised.

No, no, they meant that newcomers should learn the code . . . Wayne

Richard A. Medhurst KD6BFO. In response to the letter from Terry Weinhold N3EUL, as published in the October 1995 issue, I must say that the facts do not support his conclusion that the code requirement makes for a "higher-quality operator." A review of the "Happenings" column in *QST* for the calendar year of 1993 would tend to disprove this conclusion. The facts are that during 1993 14 licensed amateurs had monetary action or revocation of license by the FCC. One Tech (7.15%), five General (35.7%), two Advanced (14.3%) and six Extra (42.85%). As you can see, 92.85% have 13-word or better licenses. During a recent public service event in San Diego, a two-by-two call maliciously and willfully interfered with communications. That's a "higher-quality" operator? If the 2 meter band sounds like CB in Mr. Weinhold's area then there is no one to blame other than the pre-no-code amateurs. It was up to them to educate the new licensees as to proper repeater protocol. If they do not know the rules, how can you condemn them? To infer that the only "good" operators are those with code is exactly the type of narrow-minded attitude that keeps the young people out of amateur radio. I do not advocate the elimination of CW, only the easing of the 13-word requirement. I also advocate more stringent technical testing for HF privileges. I may be a lowly Tech, but I have many friends who are General, Advanced and Extra Class who come to me for technical assistance.

Jan Hair N5LVI After reading the letter on Senior Citizens Upgrade, I thought I'd write a response. Maybe who is regarded as a "Senior" is relative to a person's age. I first acquired a General Class license in 1956. Following that year, we added to the family until we had five harmonics. Busyness with family and no antenna shut me down for 17 years after the expiration of

Continued on page 87

QRX . . .

Private Ham Satellite

Bob Bruninga WB4APR may become the first ham with his own amateur radio satellite in space. The Glen Burnie, Maryland, ham hopes to have the new amateur radio satellite In orbit by next summer.

No, this is not a joke or a pipe dream. Bruninga is the director of the Satellite Education Laboratory at the Naval Academy in Annapolis and the satellite Is a departmental project. Its primary aim is to provide every school in the country with packet radio satellite access:

"We try to participate in all the SAREX missions with our students. The only problem is probably only 1% of the orbital passes is operational in the packet mode on the SAREX and you never know in advance. It is very hard for the students to go to all this effort and not be able to make a packet link to the spacecraft. So, we think that there ought to be a very low budget, low tech packet satellite up there that is always on, always operational. And every time it comes over any high school in the country the students will see something."—Bruninga

Bruninga says he plans to fly a one-watt Picosat transponder operating on 2 meter FM packet at 1,200 baud. The system is specifically designed for digipeating position reports.

"Once you get the satellite up there then we can track guys driving across the country in their recreational vehicles, we can track guys in their boats out in the bay and up and down the Atlantic...all over the world really. That's why we think there is tremendous potential for position reporting.

"I mean that's what amateur radio is. It's not sitting in your basement. As far as our ability to contribute to the state of the art and to public service, our abilities are not sitting in out basements. Our abilities are mobile."—Bruninga

Bruninga says that he already has a tentative invitation from NASA for a free launch on an experimental booster. The earliest possible launch date is in May. But WB4APR says that the date could easily slip. A lot depends on when the satellite is ready to fly. The parts are within arms reach, says Bruninga, but construction has yet to begin. *TNX Amateur Radio Newsline*

Dove S-band Is On

Still with ham radio satellite news, Jim White WDØE reports that the DOVE DO-17 ham satellite S-band transmitter is on. Jim says that a recent software load allows better power control and controllers now expect to be able to keep the pesky transmitter in operation on 2,401.220 MHz. *TNX Amateur Radio Newsline*

RF Lights

RF light bulbs are on their way and they could add to the QRN currently on the ham bands. This, after the Federal Communications Commission waives its rules to permit the General Electric Company to begin marketing a new RF-powered light bulb.

At GE's request, Part 18 of the commissions regulations has been waived. Part 18 limits on the amount of RF energy that can be conducted into the electric power lines by RF lighting devices in the band 2.2 to 2.8 MHz. GE proposes marketing to consumers an unlimited number of RF light bulbs that comply with the conduction limits for nonconsumer RF lighting devices in this band.

Commission rules already permit RF lighting devices used in commercial environments to place this signal level on the AC power lines. The FCC says that there has been no record of significant interference problems from the use of these devices in commercial environments. It also says that radio operations in the range 2.2 to 2.8 MHz are not normally employed or intended for reception in residential environment. GE was granted a waiver for one year, and the FCC reserved the right to revoke the permit if it determines that RF lighting devices operating under the conditions of the waiver create severe interference problems.

Three years ago, a California company, Intersource Technologies, promoted an RF-powered light bulb that operated at 13.56 MHz. According to the manufacturer it was designed to keep unintentional radiation to a minimum. The company claimed that its 25-watt RF bulb could generate as much visible light as a 100-watt conventional bulb but these lamps were never marketed.

And the ARRL says it has a definite interest in what kind of interference the GE RF bulb may generate. The League says that it will obtain samples of the GE bulbs for testing as soon as they are available. ARRL Laboratory Supervisor Ed Hare KA1CV says that the new bulbs should not, if properly designed, create any more interference to Amateur Radio operations than fluorescent bulbs, dimmer switches, or other similar devices found in the home. Other experts disagree. They point to the problems that a bad incandescent lamp dimmer can create for the average ham. *TNX Amateur Radio Newsline*

Airwave Auction

The Supreme Court has given the Federal Communications Commission approval to go ahead with its planned December 11th auction of 498 licenses for small businesses. A company called Radiofone Inc. had challenged the commission's cellular personal communications services cross-ownership rule, which limits cellular companies to 40 megahertz of spectrum in their cellular service areas.

But in vacating a stay issued by a Federal Appeals Court, Justice Stevens noted that allowing the national auction to go forward would not prevent the federal appeals court from granting Radiofone appropriate relief if it later found that the company's case has merit. As a result, the multimillion dollar auction will proceed. *TNX Amateur Radio Newsline*

1996 VE Test Fee

The cost of getting a ham radio license is going up again in 1996. Effective January 1st, the maximum allowable reimbursement fee for an amateur operator license examination will be $6.07. The FCC set this amount based on the Consumer Price Index between September 1994 and September 1995. It's an increase of 17 cents from the current $5.90 fee.

Actually, nobody really makes any profit from ham radio testing fees. Volunteer examiners and volunteer examiner coordinators are permitted to charge examinees for out-of-pocket expenses incurred in preparing, processing, administering, or coordinating reexaminations for amateur operator licenses. The amount of any such reimbursement fee from any one examinee for any one examination session, regardless of the number of elements administered, must not exceed the maximum allowable fee. *TNX Amateur Radio Newsline*

FCC Wireless Chief Moves

Regina Keeney, chief of the FCC's Wireless Telecommunications Bureau, which oversees Amateur Radio, has been promoted to chief of the Commissions Common Carrier Bureau. Keeney, who has been chief of the WTB since the bureau was formed last December, replaces Kathleen Wallman at Common Carrier.

Regina Keeney is the daughter of John Markey W2AAW and Marge Markey N4XZD. When she was named as chief of the Wireless Telecommunications Bureau she is quoted as saying that she had grown up in an enthusiastic ham radio family.

The FCC, in announcing Keeney's move over to Common Carrier, said that during her tenure at the WTB, she oversaw the commission's auctions of electromagnetic spectrum and worked to develop fair rules of competition in the wireless communications marketplace. Thanks to her leadership, says the FCC, the previous backlog in license application processing has been cut in half.

No successor to Keeney in the Wireless Telecommunications Bureau has yet been announced. *TNX Amateur Radio Newsline*

Paralyzed Assistance Needed

Bill Farley WA5FLG has posted a packet message asking for help for a paralyzed ham. Bill says that Lowell Richardson W5UBW, an avid DX chaser, has become paralyzed but wants to be able to communicate.

Bill says that Lowell no longer can speak. Bill is looking for any device that would help his friend who has the use of one hand only.

If you have any ideas, send them by packet to WA5FLG@K5WPH or call Bill at (505) 437-5508. He is in Alamagordo, New Mexico, and is on Mountain Standard Time. *TNX Amateur Radio Newsline*

Canada Adopts IARP

On the international scene, Canada has announced that it has agreed to adhere to the Region 2 International Amateur Radio Permit. It's the fourth country to do so and has issued the first two permits. These went to Radio Amateurs Canada

The SP-10 "Senior Spider" Transceiver

Mike Agsten WA8TXT
405 W. Bogart Rd.
Sandusky OH 44870

You may have heard (or know firsthand) that transmitter power levels of 1 watt or less can indeed "get out" and have accounted for some remarkable feats of DX. It's true.

It's also true that 1 watt, in HF skywave service, has little endurance to spare. You get lucky and snag a good one when the band is optimum and two minutes later, you're talking to yourself because of QSB or QRM at the other end! Clearly, some extra holding power is called for if you want to chew the rag or make 5-WPM Novice QSOs that, of necessity, take longer to complete. The question is, how much will it take to do the job?

When it comes to transmitter power, the sky's the limit of course, up to the legal limit for your license class, but here we also want easy construction and minimal cost to encourage beginners so we'll just split the difference between a measly 1 watt and the widely effective 100 watt levels. And the answer is...10 watts! That's right. To judge the effect of a power change, you must think in terms of dB (decibels) and not be mislead by the watts. Ten watts is 10 dB better than 1 watt and 10 dB worse than one hundred, placing it on middle ground theoretically and in terms of on-the-air readability.

The rig to follow is a simple 10-watt, crystal-controlled CW transceiver that may be built for 80, 40, or 30 Meters. You can build it and learn a little about how it works. Should it ever malfunction, just fix it yourself. There's no need to rely on the service of a distant repair facility. That's independence!

The SP-10

The SP-10 presented here is functionally very similar to its predecessor, the SP-1 (Jan. 1993 issue of *73*) which has enjoyed popularity in the QRP world. The receiver front end is triple-tuned to improve in-band sensitivity and out-of-band rejection. The dual-gate MOSFET receive mixer has been retired and its job turned over to a multifunction IC that also includes an op amp for audio bandpass filtering and a very effective audio muting switch. A low-noise audio preamp stage for increased gain rounds out the receiver improvements.

The transmitter section is pretty much the same as the original "Spider" except here it drives a power MOSFET "afterburner" producing 8 to 12 watts of RF output. Physically, the highly successful SP-1 layout has been retained wherever possible. The additional circuitry requires a larger circuit board which fits comfortably in the next size up enclosure, an RS #270-232 measuring about 8" w by 4" d by 2" h.

> ***"Your brain needs a change of pace and here you get it whenever you close the key!"***

The net effect of these changes is a quantum leap in overall transceiver performance and just a modest increase in cost and complexity. By strictly avoiding "dinosaur" and one-of-a-kind components in the design, easy duplication and maintenance for years to come is almost assured. So get with it and, next time, you'll be the one to say "Rig here is home-brew!"

Circuit Description

The heart of this radiotelegraph transceiver is continuous wave oscillator Q1 (refer to the schematic, Fig. 1). You plug a quartz crystal (more on crystals later) for the desired operating frequency into the top panel socket and Q1 circuitry provides the needed gain and feedback to sustain crystal vibration and supply RF drive to other circuits via the secondary link on T1.

Photo A. Top view of the SP-10.

During receive, incoming signals pass through L5, L4, L3 and series resonant C23/L6 to receiver input circuits T2/C32 and T3/C33 (which are top coupled by C34) and onward to the receive mixer at U3 pin 18. There, in conjunction with oscillator signal via C18 to U3 pin 1, they are converted directly to audio at U3-3, filtered by C59 to remove unwanted RF byproducts and then audio bandpass filtered by the op amp at U3-12 and U3-13, which provides a distinct peak at about 400 Hz. In receive, the audio muting transistor at U3-16 is off (open) allowing signal passage to AF preamp Q6, volume control R47 and AF power amplifier U1 (pin 2 in, pin 5 out). U1 employs a small amount of negative feedback (C52) to roll off unnecessary high-frequency components in the AF output.

Receiver fine-tuning is accomplished by using RIT control R23 to vary the tuning voltage (via R1) to D1. This special tuning diode transforms RIT rotation into variable capacitance which, in conjunction with L1 and Y1, alters the oscillator frequency. Normally, this receiver is properly tuned when there is a 400-Hz difference between signal and oscillator. The resulting beat note provides peak output because it is centered in the audio bandpass response. Frequencies higher and lower receive less amplification. This is how selectivity is

provided; the desired signal is louder unless interference is overpowering.

Automatic receive-transmit switching (QSK) is initiated by closing the key. Q8 switches on, rapidly energizing the 12T bus which, in turn, accomplishes the changeover to transmit by switching several circuits. 12T via D8 mutes receive audio by placing a short circuit at U3-16. It turns on sidetone generator Q7 (a unijunction transistor or UJT) via R38 and R39. Sidetone allows you to monitor your telegraph sending quality by providing a nice, tight feedback loop that includes ear, brain, fist, and key. The sidetone in this rig also provides an important secondary function. Its complex, harmonic-rich output soothes your brain by dispersing all those headache-forming neural knots that may come from excessive sine wave exposure during receive. Your brain needs a change of pace and here you get it whenever you close the key!

Moving onward, 12T via R25 and Q5 grounds D1 tuning voltage to provide transmit offset which allows same-frequency transmit-receive with other stations. It switches Q3 on, enhancing oscillator output level via R5 and assisting transmit offset with C3. Finally, 12T keys Q4, which permits Q2 to amplify the incoming oscillator signal. Q2 output via low-pass filter L2 and resistive pad R14-17 then drives final RF power amplifier Q9 to full output of 8 to 12 watts, depending on band, power supply and transistor grade.

Harmonics present in this raw power are attenuated to insignificance by low-pass filter L3-L4-L5 and associated capacitors. Since the receiver input is tied directly to transmitter output at C23, D4-D7 are included to protect the receiver. Transmit RF turns them on and, while in conduction, they place a near-short at the junction of C23 and L6, breaking up the series resonance and forcing C23 and C22, because of their relatively low capacitance, to look like a high impedance during transmit, thus blocking most of the RF. This technique was actually developed for radar equipment where a sensitive receiver and high-power transmitter had to share a common waveguide. What you see here is the same principle in a less pure but still adequate form.

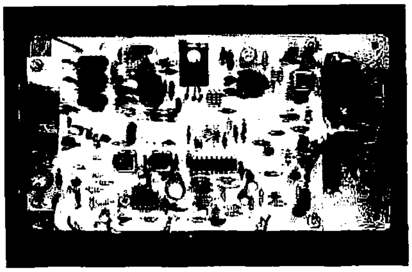

Photo B. Bottom view of the SP-10.

Construction

In the top view photograph of the SP-10, you can see the octal-type crystal socket in the left-rear corner. Since this socket holds two FT-243 or similar crystals, DPDT switch S2 is provided just in front to select one or the other. TB1, a four-lug terminal board, mounts along the rear edge of the top panel, near the right-rear corner. Its terminals are numbered 1 to 4 going from left to right. Connections to TB1 are DC power to 1 (+) and 2 (-) and antenna system to 3 (coax shield) and 4 (center). Along the right edge are 3.5-mm jacks for speaker/headphones (J2-rear) and external telegraph key (J1-front).

The built-in telegraph key is just left of the jacks. Its arm, a 3" strip of .025" thick brass or aluminum, is mounted on 1/4" spacers and grounded to the top panel by its two mounting screws. The key knob, a rubber or plastic equipment foot, is fitted or glued to the hex nut attached with machine screw, up through the arm. The head of this screw is the upper contact. The key contact beneath the arm is a 6-32 brass machine screw with head filed flat. This screw is insulated from the top panel with a shoulder washer above and fiber washer below, and secured with flat washer, solder lug (for connecting to) and hex nut.

The two knobs front and center on the top panel are Volume control R47 on the right and receiver incremental tuning (RIT) R23 on the left. Just left of RIT is slide switch S3, unused here but available for extra audio filtering (to improve selectivity) or other contingencies. Left of S3, in the left-front corner is DC-power control switch S1.

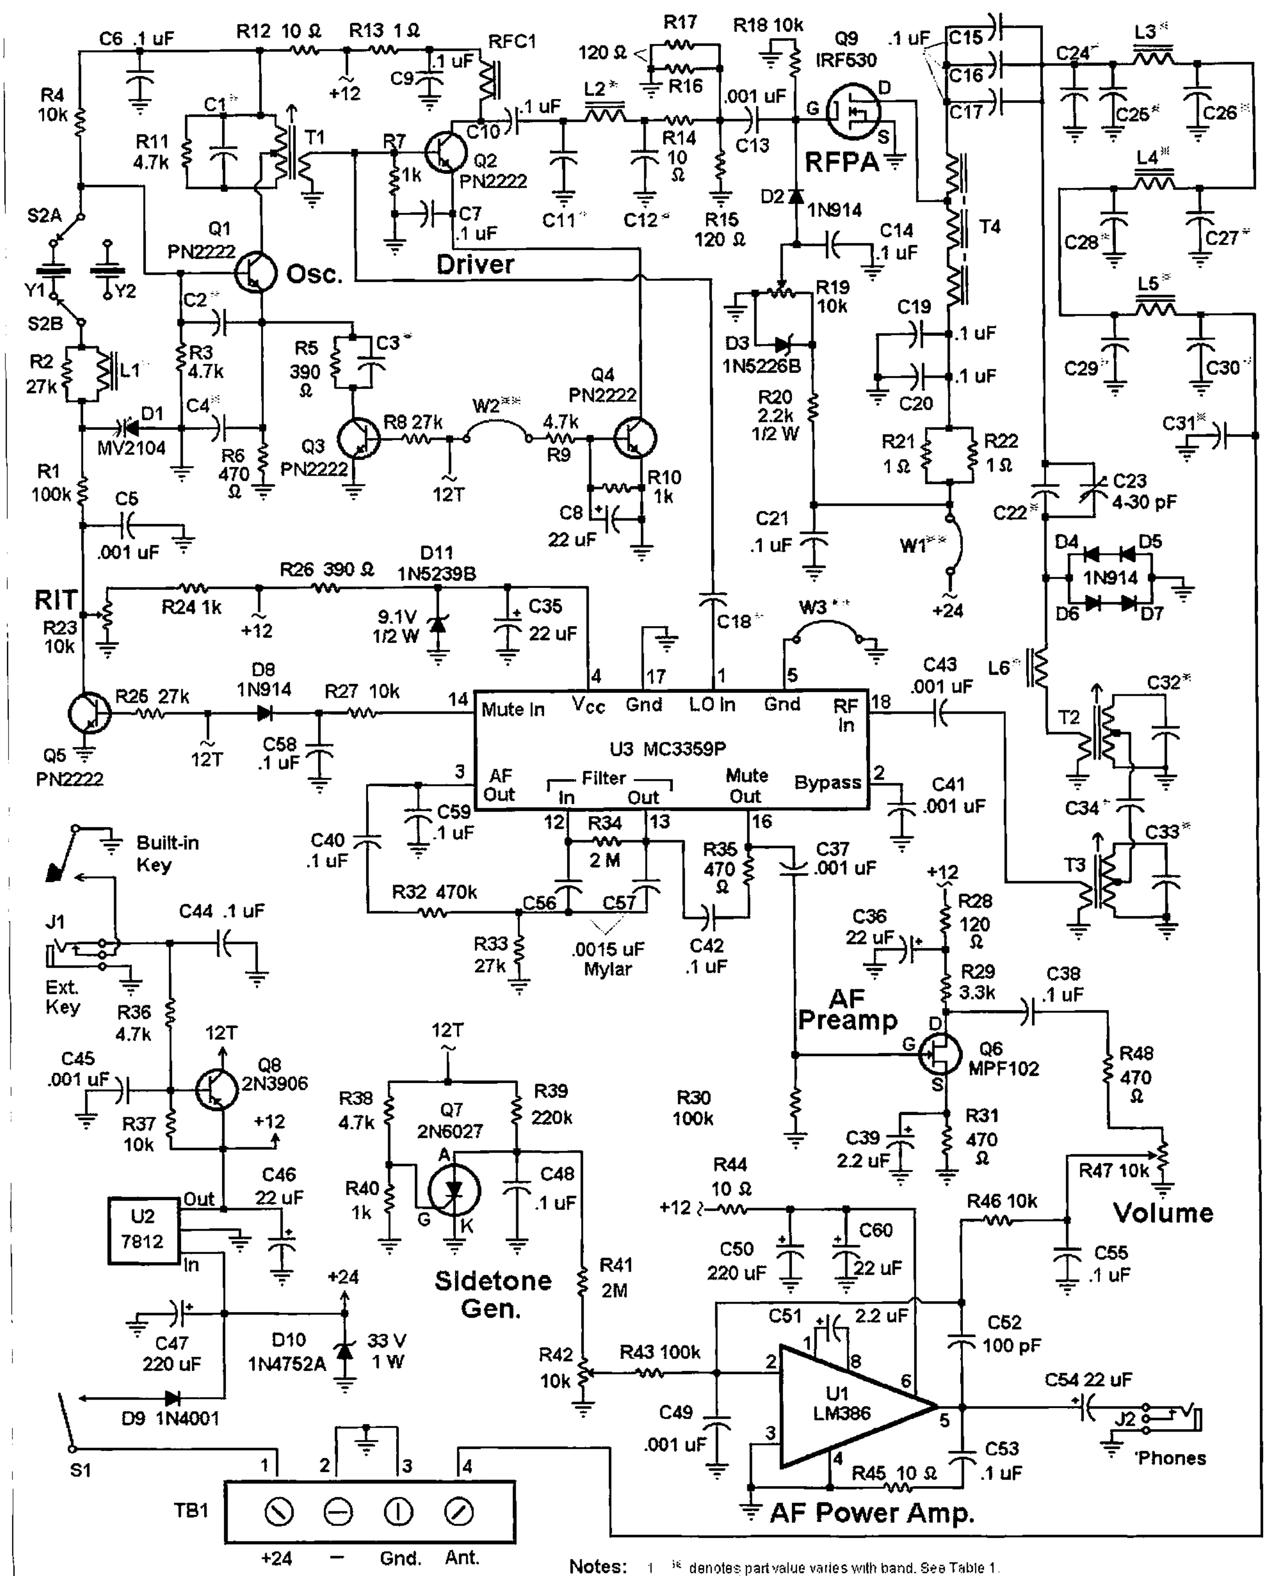
Running front to rear between RIT and Volume, and below the top panel, is a 1" wide by 3" long by 3/8" thick solid aluminum slab that provides heat sink and mounting platform for RF power amp Q9. This slab, to further increase heat dissipation, is attached directly to the aluminum top panel with three machine screws, heads visible in the photograph.

Most of the project is contained on the PC board depicted by the etching pattern in Fig. 2 and the parts overlay, Fig. 3. Of special note on PC board assembly, voltage regulator IC U2 needs 2 to 3 square inches of heat radiator coupled to its mounting flange. I cut and bent a piece of .025" aluminum sheet as shown in photo B (inside view) and on the parts overlay, and installed it between U2 and the PC board.

T4, the trifilar-wound matching transformer, uses two of the specified core placed side-by-side. The wire winding holds them together, no problem. Don't be intimidated by "trifilar winding." All you do is cut three equal length wires and twist them into a bundle. Thread the bundle onto the core until you have the specified turns count. It should look like an octopus with six tentacles coming off the bottom. Trim excess wire but allow enough for connections and installation. Now you have three wires on the core, arbitrarily designated A, B and C, and color-coded or tagged for easy identification. Connect the end of A to the beginning of B. Connect the end of B to the beginning of C. The beginning of A and the end of C remain single and go to "Com" and "Out" at T4 on the PC board. The two cross-connections go to "X" and "in." Voilà!

Because Q9 is the last part installed, even after the PC board is mounted to the top panel, provision must be made for connecting it to the top side of the board. I used short "flea clips" as mounting posts at holes G, D, and S. Anything snug enough to remain tight when reheated will do the trick here. In other words, you don't want the mounting posts to come loose from the PC board when you're attempting to solder the leads of Q9!

With the PC board complete, use it as a template to mark its corner mounting holes on the inside of the top panel as shown in Photo B. The heat sink slab mentioned earlier runs from beneath the rectangular Q9 cutout to the area between Volume and RIT. Drill and tap a 6-32 mounting hole for Q9's flange in the heatsink, positioned so Q9 leads will bend and reach the PCB mounting posts.



Notes:
1 * denotes part value varies with band. See Table 1.
2 ** W1-3 represent bare wire jumpers needed with the accompanying pcb layout.
3 Both C9 and U2 require a heatsink. See text and photographs for details.
4 Component ratings: Unless specified, resistors are 1/4 W, electrolytic capacitors are 35 V and ceramic disk capacitors are 100 V.

Figure 1. Full schematic diagram of the SP-10 "Senior Spider."

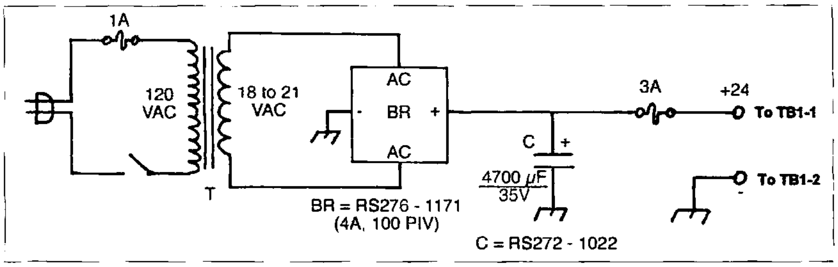


Fig. 4. SP-10 power supply.

Follow the photos to lay out and install the remaining top panel parts, the positioning of which is much less critical than the need to keep Q9 cool.

Except for the short ANT/GND and Y1 wires, connect the PC board to top panel components as shown on the schematic diagram or parts overlay. Hinge the board over and mount it to the top panel on 5/8" metal spacers, and then connect the short wires to TB1 and S2. Check to ensure the copper side of the PC board is not touching any panel components like potentiometers or jacks. Lastly, install Q9 to the heat sink using a heat conductive insulator pad and 6-32 Teflon or nylon screw or a TO-220 transistor mounting kit, to couple the flange thermally but not electrically to the heat sink slab.

Power Supply

A suitable power supply for the SP-10, one supplying 18 to 28 VDC at 1 amp, can be as simple as a DC wall adapter or a pair of 12V batteries wired in series. There's no need for a fancy, electronically regulated unit. Precise regulation, where needed, is already supplied by U2. The external supply should, however, be beefy enough to hold its output voltage within 20%, going from key-up to key-down. For example, a source measuring 25 VDC should drop no lower than about 20 volts when you close the key. The no-load input can be as high as 32 VDC; beyond that point, protection zener D10 may conduct and if it does, it will probably short circuit in the process of protecting the SP-10 from overvoltage.

If you wish to build a power supply from scratch, the classic transformer-rectifier-filter arrangement shown in Fig. 4 will work just fine. Regardless of the power supply you choose, be sure to provide an inline fuse in the plus lead running to TB1-1. Start off with a 1-amp fuse if possible and, if all goes well, upgrade it to 2 or 3 amps for normal operation. This conservative approach to firing up new, untested equipment will minimize casualties should anything be amiss.

Crystals

The operating frequency of the SP-10 is controlled by a single crystal in transmit and receive. With crystals, you give up the ability to wander (or drift!) around the band in exchange for excellent frequency stability, intrinsic dial readout (frequency is marked on the crystal) and simplified project tune-up, requiring very little test equipment. For the beginner, or the old-timer into "radio karma," crystal control is a good way to go.

The actual crystal is a thin square of quartz too fragile and sensitive for direct handling. Rather, it is mounted in a holder which, depending on type, plugs into a crystal socket or is wired directly into the equipment. The octal crystal socket on the SP-10 accepts two of the popular FT-243 holders, having a pin spacing of .486" and a pin diameter of .093." Types HC-17 and Petersen Z-9 are also compatible. In general, any fundamental crystal with a frequency in the chosen band will work if you can adapt it to plug in. For example, even the miniature HC-18 holder with leads instead of pins may be wired to the base salvaged from an unneeded octal vacuum tube, which will then plug in.

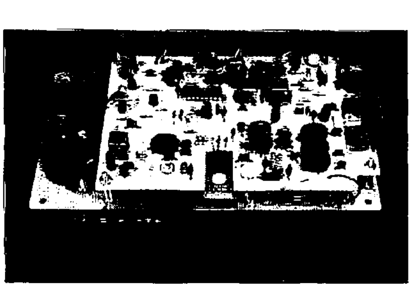

Photo C. The SP-10 at an angle.

Getting crystals is like ordering pizza. Unless you are buying a stock or popular frequency, they are tailor-made by a manufacturer upon receipt of an order. That's why delivery can sometimes take 2-3 weeks or more; you must allow for lead time! Some manufacturers require the Y1 specifications provided in the Parts List while others will do the job if you merely order "amateur-grade crystal" and specify the frequency.

If you're a Novice, don't crowd the edges of your subband when ordering crystals, unless you have the means to ensure the crystal you're using is "in-band." The reason is, a general purpose or amateur-grade crystal ordered for, say, 7102 kHz, may actually put out on 7100. It's a matter of manufacturing tolerance and circuit correlation. If in doubt, give band edges a wide berth.

Tune-Up

The key to a smooth, uneventful tune-up is to do a careful job during construction. Having done your best, let's see if it works! On the PCB, set R19 Bias and R42 Sidetone each to midrange. Connect the power supply to TB1-1 (+) and TB1-2 (-) and a 50-ohm dummy load with relative power meter or wattmeter in line to TB1-3 (coax shield) and TB1-4 (center conductor). Lacking this test equipment, build the simple terminating RF indicator shown in Fig. 5 and connect it to TB1-3 and TB1-4. This gizmo provides a suitable resistive load for low power transmitter testing, as well as a visual (and thermal—it gets warm to hot!) indicator of RF output.

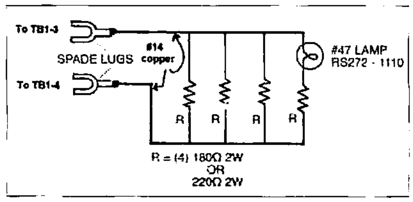

Fig. 5. Terminating RF detector.

Plug a speaker into J2. Insert a crystal into the socket and select it with S2. Switch on power with S1, close the telegraph key and adjust T1 for maximum RF output indication. Adjust R42 on the PCB for desired sidetone level. Replace the dummy load with an antenna or signal generator at the crystal frequency and adjust C23, T2, and T3 for best reception.

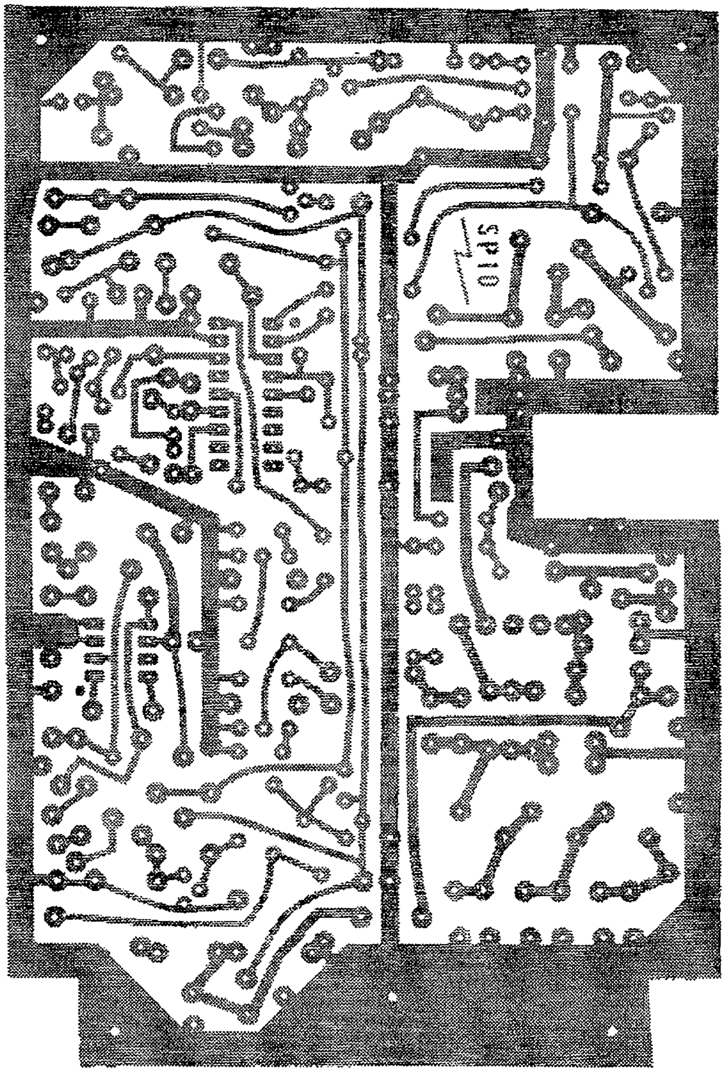

Fig. 2. PC Board foil pattern.

Some patience is called for with the antenna method; you may need to wait for a signal strong enough to be heard through the as yet unpeaked front end. A temporary clip-lead jumper from the anode of D6 to the upper lead of C34 may help by allowing you to get T2 and T3 in the ballpark first. Then remove the jumper to peak C23 and touch up T2 and T3.

On the Air with the SP-10

Like all modern transceivers, the SP-10 prefers to see a 50-ohm antenna system with low SWR. The classic half-wave dipole comes close to ideal without the use of extra matching techniques. Other antennas like the G5RV or random wire will require an antenna tuner to provide an acceptable load. If operation into a less than perfect match is unavoidable, it might be wise to reduce the operating voltage from, say, 24 VDC to 18 VDC. This will reduce the adverse effect (Q9 overheating) of a somewhat high SWR.

With its rather broad selectivity, it can be questionable whether or not signals heard on the SP-10 are close enough to your crystal frequency for a QSO. Those that decrease in pitch and approach zero-beat with RIT control moved fully counterclockwise are very close. Others may be workable if the operator tunes around for your signal.

Though 10 watts is considered low power, it's right up there with the popular one-tube 6L6 transmitter (and countless variations) that propelled tens of thousands of hams into the ether in their early radio careers. The receive section is certainly no worse (and probably better) than those "drifty," broad-tuning superhet Novice receivers we once cherished and still remember fondly. They did the job! And on most any night the SP-10 can be your doorway into a wonderful world of Morse and static, faceless names, exotic places, and colorful QSL cards—all the more exciting when you build the rig yourself!

SP-10 Condensed Parts List

C1-C4, C11-C12, C18, C22, C25-C34	(see table 1)
C23	4-20 pF trimmer, Mouser 24AA022

Low Cost Switching Power Supply For HF Transceivers

by Phil Salas AD5X
1517 Creekside Drive
Richardson TX 75081

I have been using a Ten-Tec 938 switching power supply for some time with my Kenwood TS-50S for portable operation. This switching power supply is very small, efficient, and lightweight (2.5 pounds) and lets me operate my TS-50S at 50 watts output continuously. However, for base station use I wanted the full 100-watt output power capability of the TS-50S. A full 20-amp linear power supply weighs three to four times what the TS-50S does, and is two-to-three times larger than the TS-50S. It just didn't seem right to have a power supply that overwhelmed the TS-50S in size and weight. What I wanted was a small, lightweight switcher with 20-amp capability. Unfortunately, no one seems to make these at this time for amateur use, and commercial switchers are very expensive. Oh, what to do!

I, like many of you, receive lots of catalogs of surplus electronic stuff through the mail. Many of these catalogs list all kinds of DC power supplies, both new and used. My favorite surplus catalogs are from Marlin P. Jones & Associates (407-848-8236), All Electronics Corp. (818-904-0524), and Hosfelt Electronics (800-524-6464). I recently noticed that Marlin P. Jones & Associates was advertising a 12-VDC 20-amp switching power supply for only $49. This was a used Lambda power supply that is 9" x 4-7/8" x 2-7/8" and had a shipping weight of only six pounds. This seemed great, but could it be made to operate at 13.8-VDC output? There was only one way to find out—so I ordered one.

"This surplus treasure turned into a 20-amp switching power supply that is smaller than a TS-50S, weighs less than six pounds, and costs less than $60 total!"

A few days later the power supply arrived. It is a used Lambda LYS-W-12 power supply rated at 20 amps continuous at 40 degrees C, 18 amps at 50 degrees C, and 15 amps at 60 degrees C. The input to the supply can be 105–132 VAC at 47–63 Hz, or 130–160 VDC. This power supply has no switches, fuses, connectors, or indicators. When I removed the cover, I found that the DC output connectors were #10 studs on the PC board, and the AC inputs were just pins on the PC board to solder a line cord to. Everything was well marked on the printed circuit board, along with an output voltage adjust potentiometer. So, first things first—could I operate the supply at 20 amps at 13.8 volts? I had a 20-amp load made up of twelve 8-ohm power resistors. I connected a voltmeter and oscilloscope across the load which was attached to the DC studs, soldered an AC line cord to the AC input pins and plugged it in. The output came right up to 12 volts! I next adjusted the voltage adjust pot and easily got 13.8 volts! Finally, I measured 150-mV p-p output voltage and 10-mV p-p ripple on the DC output at full load with my oscilloscope.

Now I needed to make the power supply user friendly—I needed to add a switch, fuse, indicator, line cord, and DC output cord to the unit. This was pretty easy to do as the basic frame that the power supply is mounted in has a number of small unused holes in it. Apparently this chassis base is used on a number of different power supplies. Fig. 1 shows a side view of the power supply with the cover removed and the components I added. On the 4-7/8" x 2-7/8" blank side of the supply, I drilled out the two unused holes on the left side (See Photo A) for a SPST 10-amp switch (Radio Shack RS 275-324), and an LED. On the back, silk-screened side (See Photo B), I drilled out one hole large enough to pass a pair of #12 wires for the DC output, and one hole large enough to take a #8 screw for a ground stud. The photographs illustrate this very well. There is already a "half-moon" cut out in the back that easily passes an AC line cord. On the inside of the power supply, I wired an in-line fuse holder (with a 5-amp fuse) in series with one side of the AC line cord, and wired the line cord to the switch and AC input pins on the printed circuit board. I wired the LED with a 750-ohm series resistor to the solder lugs on the 12-volt studs. Next, I attached #10 solder lugs to the #12 wire that passes out of the supply and then attached the

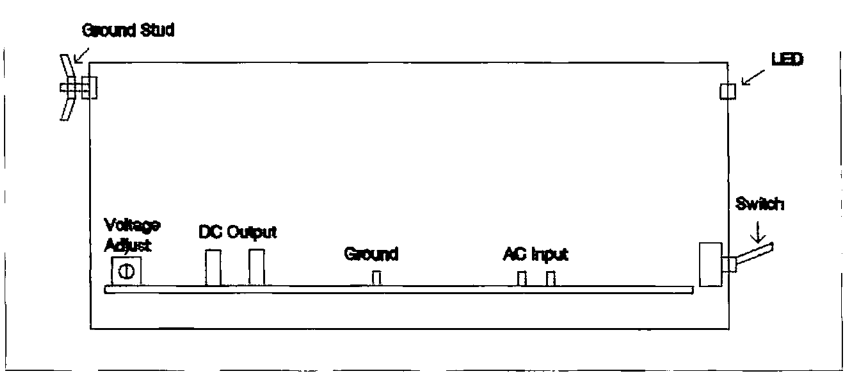

Fig. 1. Switching power supply side view.

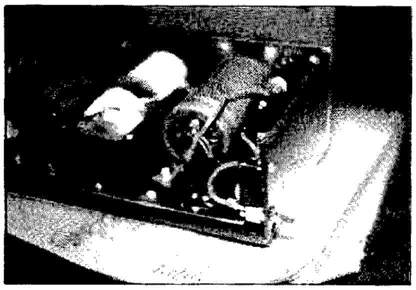

Photo A. Blank side.

solder lugs to the DC output #10 studs. The DC output is floating with respect to ground, so attach a wire from the negative DC terminal to the ground pin on the printed circuit board. Finally, I terminated the #12 wires on the outside of the power supply with a 20-amp Radio Shack "Molex-type" female connector (RS 274-154). The ground stud for tying into your station ground is a #8 screw with the screw head mounted inside the power supply. Use lock washers inside and out, and a #8 nut on the outside to hold it in place. I used a #8 wing nut and two #8 washers to make an easy-connect ground stud.

That's it. This surplus treasure turned into a 20-amp switching power supply that is smaller than a TS-50S, weighs less than six pounds, and costs less than $60 total! And, it is perfect for both base station and portable use. Since this is a surplus power supply, it will probably show up from time to time in different surplus catalogs. So, keep your eyes out for this or similar power supplies. These commercially rated switching power supplies are real treasures and are adjustable for amateur 13.8-volt DC power requirements. 73

Capacitors are 100v ceramic disk type. For inductors, wind turns using the enamel wire gauge given on the toroid core specified.

SP-10BBM, $16 ppd. US/CAN, includes bare PC board and step-by-step construction manual. PC board and parts (including band parts for 80, 40, 30 meters), and case parts including drilled and tapped heat sink. The RS 270-232 case and crystal(s) are not included but a mailer for sending in your top panel for free master template marking (with metal work option extra) is included. This pricing is valid within four months of publication. Order direct or send an SASE for current details. 73

Simple Mobile Protection

Safely ward off those evil spikes.

L. VanProoyen K8KWD
8330 Myers Lake NE
Rockford MI 49341

I consider a "good" mobile radio installation one that is unobtrusive. With the variety of radios with detachable control panels, it's fairly easy to go mobile without having your car's interior resembling something like the space shuttle's cockpit.

As a further aid in achieving an unobtrusive installation, many vehicles include one or more blank DIN panels on the dashboard, sized perfectly for installation of many of the detachable control panels. I know of one instance where a ham was able to install an entire Kenwood TS-741 in place of such a panel, and when he completed the installation it looked like a factory original option.

I have one problem with unobtrusive installations, though:Unobtrusive means not noticeable, which means I can forget to shut my radio off when leaving my car. Even those "wheat grain" bulbs can kill a battery, given enough time.

The Ignition Key Control Solution

Because of my forgetful nature, I like it when everything turns off when I remove the ignition key. Achieving total key shutoff can be complicated since most manufacturers recommend connecting the radio's power cable directly to the battery. This is particularly important with 100-watt class radios, which use a lot of current. Also, many manufacturers recommend shutting your rig off when starting the car's engine. That's because radios can be intolerant of irregularities in their power source. The starting process can produce deep sags in the vehicle's supply voltage and high amplitude spikes, which could zap your radio.

To meet my first need (direct battery connection), I used a relay mounted in my engine compartment near the battery (Photo A). Use of a relay is a legitimate method of connecting power to a radio. The relay I used is one commonly used in mobile two-way radio installations. I got it, together with a fuse block, from a local two-way shop. It can handle 30 amps continuously and has an 80-ohm coil.

I've seen similar relays for sale at auto accessory shops as horn-relay replacements. The relay's contacts should be rated for at least 50% more current than the specified maximum current of your radio, and the relay should be a sealed type (no sparks).

The power control relay must be well secured to the vehicle. The relay and fuse block should be screw-anchored to the inside wheel-well cowling or some other suitable surface near the vehicle's battery. Locating a place can be a challenge in some feature-packed cars. A vehicle's engine compartment is no place for loose items. Also, check out what you might be drilling into before drilling.

Many vehicles use batteries with side connection lugs. I've seen some "interesting" wiring techniques done

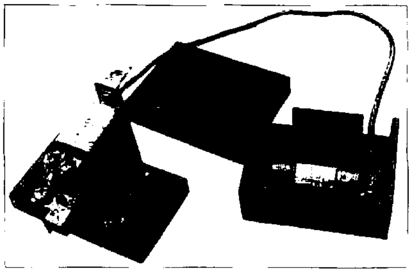

Photo A. Typical control relay and fuse block suitable for use with 100-watt mobile radios.

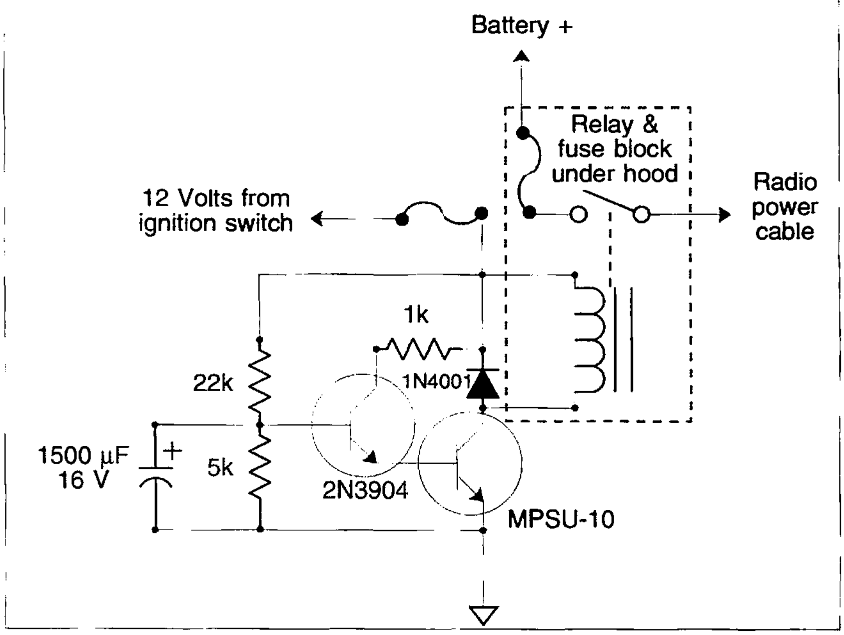

Fig. 1. The on-delay timer circuit.

when trying to connect a radio cable to this type of battery. Most auto accessory stores carry an adapter block for connecting auxiliary wires to such batteries; I recommend using one.

An On-Delay Circuit

A simple method of controlling the power relay circuit would be to tap into the car's accessory circuit, such as at the car radio's fuse. Most vehicles are wired so that the radio's power turns off when you're starting. While this works OK, I didn't like power coming on, dropping out, then coming back on again, so I decided to use a delay circuit that would keep the power relay from energizing for a few seconds after key-on.

After failing to make something simple using a 555 timer IC, I settled on the circuit shown in Fig. 1. I used two transistors I had available because I needed a combination of a relatively high RC time constant circuit that limited the base current, together with high current switching. You could probably substitute a single, high-gain Darlington-type device and get the same results.

Using the values shown, the circuit provides about 10 seconds delay before the relay pulls in. I built the circuit on a small piece of perf board, as shown in Photo B. The circuit layout is not critical, although it should be built to fit some type of enclosure that can be secured to the vehicle somewhere out of the way, like up under the dash.

I used a 1,500-µF capacitor as the basic time-delay element. It charges through a 22k-ohm resistor until the 2N3904 is forward biased and conducts, thereby switching the MPSU-10 on. If you want to change the time delay, substitute other capacitor values. Don't

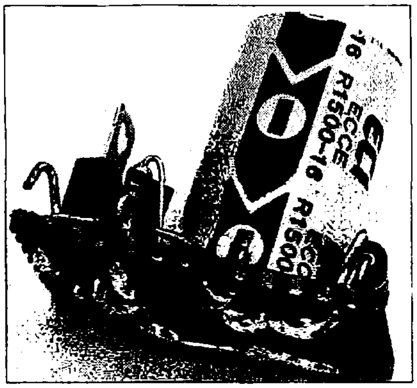

Photo B. The on-delay timer construction details.

tinker too much with the resistor values as they were selected to produce the proper base-emitter current flow. Note that I used a 1k-ohm resistor in series with the 2N3904's collector. This resistor limits the MPSU-10's base-emitter current, and it also serves to keep the 2N3094's collector current within proper limits.

I mounted my entire assembly inside a small snap-tight plastic box and drilled holes for the wires. The only connections necessary are the source of key-switched +12 volts, ground, and the relay coil return.

Connecting to the Vehicle's Key Circuit

A convenient method I've used to pick up key-switched +12 volts is by using a modified "blade" type fuse (Photo C) and inserting it into an unused slot in the vehicle's fuse block. Most newer vehicles use this type of fuse, and I can usually find an unused spot in the fuse block that is key-switched.

"The judicious use of fuses is very important when doing automobile wiring (note the in-line fuse I use with my modified blade fuse)."

In the event there is no available slot for the fuse, you can substitute a modified fuse for an existing fuse, e.g. the radio fuse, but if you do I would recommend modifying a fuse that is rated correctly, not the 20-amp one I used. The judicious use of fuses is very important when doing automobile wiring (note the in-line fuse I use with my modified blade fuse). I used a 1-amp fuse in the line to my delay timer circuit and power control relay.

One note of caution if you decide to replace the broadcast radio's fuse: My newest car has a factory radio that's equipped with a password-protected theft-deterrent feature. If this radio is disconnected from battery power without defeating this protection scheme, the radio will become totally useless when reconnected. I'm told not even Delco can help if you turn this feature off. It would be wise to check with your dealer to find out if you may have such a radio prior to disconnecting it!

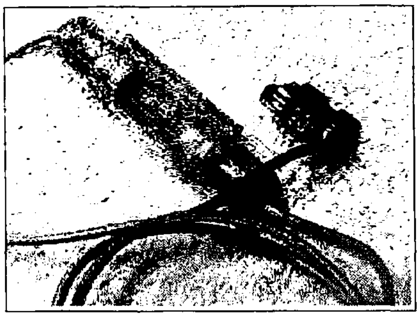

Photo C. Modified "blade-type" fuse useful in connecting to a car's key-switch circuit.

While on the subject of fuses, if there's a rule to consider above all others, it's fuse everything! Don't underestimate the dangerous potentials of an automobile's electrical system because of its low voltage. A car's battery is a powerful energy store that can produce explosions, fire, and bodily harm, if not treated with respect.

Special consideration should always be given to vehicle wiring. From a general safety standpoint there should never be any loose wires. Wiring in an engine compartment should be routed to be clear of any potential hot spots, e.g. exhaust manifolds, etc. Locations near fans, pulleys, and belts, should also be avoided. After locating a safe path for running wires in the engine compartment, the wires should be tied down using cable ties.

The radio's controls should be located such that you do not have to take your eyes off the road to operate the radio.

Safe mobiling, everybody! 73

Going Public

Put a different kind of ham on the screen!

Jeff Brone WB2JNA
108 Shiley St. Apt. B
Annapolis MD 21401

We need to make the public more aware of what we do. As ham operators, we could benefit much by enhancing the public's knowledge of our hobby. The rewards would be great. We could gain operators and have more influence in the world. The prestige we acquired would give us power, expand our possibilities, and maybe even help us get better tables at restaurants. In the past I have mentioned to headwaiters that I was a ham, but it did me little good, although I knew that they were impressed because they did that thing that people do when they're trying to hide their being impressed. Their eyes glazed over and they looked bored. I wasn't fooled by that, but I was still disappointed with my table. Think about this: We hams have a very exciting hobby. We handle emergency messages in disasters; we communicate with people all over the world; we further good international relations; and we use solder! What we do is fascinating, yet relatively little is known about us by non-hams. Why? In a word: popular culture.

Americans love their TV and movies, and we hams just haven't been exposed enough in those avenues. I believe that in the TV program "Alf," Willie, the father, is a ham, and in "The Simpsons," one of Marge's sisters is a ham, as is Bart's schoolmate who calls himself, appropriately, "Ham" (the boy is kind of a nerd, which really doesn't help us). Radio communications plays a part of most every deep sea submarine movie, but that's only tangential publicity for us. I do remember that in the Mel Gibson film "The Man Without a Face," about a deformed, lonely ex-schoolteacher. I was sure that I saw some QSL cards on the wall of his character's house. Still, these are small victories. If we are to break into the public's mind, it's going to have to be by our own hand, or, as I shall explain, pen.

The solution is simple: Write the vehicle ourselves. We need to write the screen play or TV show that will give us the notoriety we so deserve. With that in mind, I have come up with some ideas for just that exact movie or TV program that will do the job. And yes, I will remember all the little people that I met on the way to the top.

First, I propose a TV situation comedy. America loves them, and the right ones capture the imagination of the whole country. Mine is a delightful, family-oriented comedy about Marconi- I call it "Darn that Guglielmo!" In it, Marconi is an average-guy brilliant inventor just trying to make ends meet and keep his family happy. I envision one episode where his wife is out of town and he has to make dinner for his two children and his tough old boss, Mr. Prendergast. The usual comic machinations ensue: Marconi lets the rice boil over, he puts too much soap in the laundry, and he discovers wireless radio and forever changes the face of communications. Also, I think something really funny could happen with some spaghetti, though I haven't worked out the details on that one.

I'd like to see Tony Danza in the title role–he's funny, he's likable, and he's Italian. I think this show would be very popular with brilliant European inventors living in New England and the Canadian Maritime Provinces. I've heard that is a very important market group.

My next idea is exciting because, at last, we have a "ham radio hero" in a feature film. It concerns a combination ham and martial arts expert who specializes in CW operating. I call it "Morse Code of Vengeance." As a young child, he was very shy and had difficulty talking with others. He finds himself through two pursuits: CW ham operating, because it allows him to overcome his fear of speaking up; and martial arts, because it allows him to break things. As he matures, he blends the rhythms of self defense movements with the rhythm of CW. Later, he is called on by his government to break up an international ring of electronic equipment thieves. This film has everything: action, adventure, romance, and electronic keyers. In the final scene the hero, and a small group of elite commandos, dressed in green military fatigues and callsign baseball caps, infiltrate the criminal's lair while they communicate on HTs. As the hero confronts the head thief in a final showdown, the hero dramatically challenges his foe with "C'mon baby, let's QSO."

I'd like to add that there's no reason why the hero in this film can't be a woman, with very few plot changes necessary. Use of a female hero may make the film even more popular, although its name should be changed. Some suggestions are "Velvet Fist of Revenge" or "YL: This Time It's Personal."

Made-for-TV movies have a large following, and we could certainly tap into this market. My idea is a steamy romance called "CQ for Desire." It has deep emotional conflicts, searing passions, and radio equipment. Eddie Ribalski, a rough-edged longshoreman ham in Galveston, TX, uses the legal limit of output power and wouldn't think of operating without his linear amplifier turned on. He loves his loyal wife, Linda, and everything is fine until he meets Heather Arnold, a career woman who has risen to the top of the breakfast cereal buying industry and operates only low power. Initially, Eddie hates her, but they gradually become friends until that climactic night when he takes her into his shack and lets her operate his rig. She is intoxicated by the power and can't get enough of it. He is thrilled by his influence over her and lets her operate whenever they can meet. They know it's wrong, but they can't stop. Finally, Eddie's wife finds out and confronts him about the relationship. He vows to break it off, and Eddie and Heather meet later on a windy hilltop, right next to Eddie's antenna tower. They say good-bye, and Heather tells him, "It was too much, far too much for either of us to control, but a little bit of you will be in my feedline forever."

I know what you all must be thinking: "How can I come up with brilliant concepts like these?" I must admit, I have a lot of ideas, so many that it's kind of scary. Actually, my friends call it "disturbing," but you see my point. However, you can have lots of fun getting ham radio into the mainstream in other ways. Get involved in a special events demonstration station, teach a class in radio, show a friend or neighbor your rig, or just let your natural enthusiasm show as you describe your hobby to your friends or co-workers. If you find yourself getting really carried away, take a deep breath and repeat quietly "Boy, this is fun."

Please, don't steal any of these ideas.

Tesla:

Bust The Smithsonian

John W. Wagner,W8AHB
3890 Tubbs Road
Ann Arbor MI 48103-9437

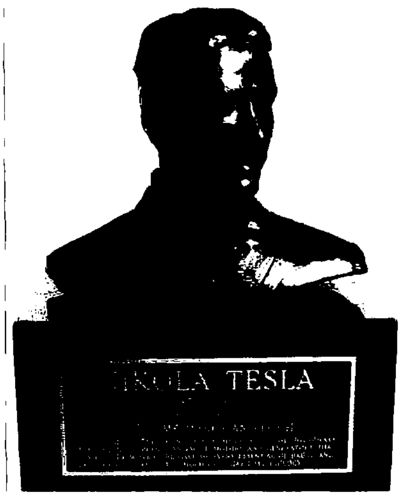
In the spring of 1983 I was browsing through the Allegheny College Library and found a book titled *Prodigal Genius, The Life of Nikola Tesla* by John J. O'Neill (1944). I had known about Tesla and his famous coil from my high school days 40 years earlier, but this was my first opportunity to learn more about the man whose coil made fascinating sparks. Regrettably, his coil was the sorrowful extent of my knowledge of Tesla, and likely it is as much as most people know, if indeed they recognize his name at all.

The first two pages of O'Neill's biography are powerful. After more than 12 years I can't forget his words. In short, I deem it a book of epic proportion. When I looked at the inside of the back cover, I was amazed to find that the book had been taken out only eight times in the past 38 years. How could this be? Was I overestimating the importance of its message? I didn't think so, and I still don't.

The same can be said for the next Tesla biography I discovered, *Tesla, Man Out of Time* by Margaret Cheney (1981). It has a powerful introduction by Leland Anderson, our country's foremost authority on Tesla. It is by far the most completely documented book available today on Tesla.

Class Hero

I had been teaching English Composition and my first thought was, "How interesting it might be for my students to learn the story of Tesla's life—it just might help me breathe some fire into their writing." The more I read, the more I was able to impart to my students, and the more they became inflamed with enthusiasm—not only for writing but for a desire to wave Tesla's banner. It seemed we had discovered a secret, if not an outright flaw in history. Why was it that so few people had



ever heard of Tesla? We decided to write letter stories to people and tell them about our discovery.

At first, and without realizing it, Tesla had become our class hero, and my students now became excited about writing. We developed a mission—to tell as many people as possible about Tesla. I was reveling at the writing successes in my classes, so I continued this activity with succeeding classes for several years.

One school year, 1986-87, was particularly exciting. Someone brought to our attention an interesting situation that existed in Madison, Wisconsin. We learned that several years earlier someone had named streets after famous scientists, including Tesla and Marconi. The city fathers spelled "MARCONI" correctly, but somehow they had misspelled Tesla's name as "TELSA" on their street sign. We also learned that a University of Wisconsin professor and chairman of the History Department had petitioned Madison officials to correct the spelling of Tesla's name, but his pleas to City Council were rejected repeatedly until he finally abandoned his crusade.

This was exactly the sort of challenge my students wanted and needed. We bombarded Madison with letters to City Council, the newspaper, residents on "TELSA" Street, the mayor, and even the mayor's wife, chiding them to correct Tesla's misspelled name. We argued, "After all, Tesla was an honored American citizen who gave much to the world;" and, "How would they like to see Washington's name spelled incorrectly on street signs?" The dispute raged for months and our story made the front page of the *Wisconsin State Journal*. One council member was particularly distraught over the issue. He called one day and begged in so many words that we "get off their backs." We refused to relent because we knew we had truth on our side. Five months later we received a letter from the City Clerk advising us they had corrected the street signs. This was confirmed later by a photograph one of my students took while traveling there.

One Saturday morning two years later my doorbell rang. It was a former student and her father. She told me that for the past three years she had not forgotten our Tesla story. It had made such an impression on her that she had persuaded her father, an accomplished sculptor, to render a Tesla bust for our class... that is, if this was something I really wanted. It took about a microsecond for me to agree to their generous offer. They explained that I would have to pay for the materials, but there would be no charge for the work. I was ecstatic and many thoughts ran through my head. We could put the bust in our classroom, or perhaps donate it to some museum.

When the clay model took better shape and I could see how magnificent it really was, the sculptor asked what preference I had for the final cast. We decided on bronze. We also decided on a granite base and a bronze plaque telling of Tesla's

eminence in the field of electrical science. I worked for weeks at my computer keyboard composing various inscriptions for the plaque and consulting Margaret Cheney and Leland Anderson for guidance. Finally, I decided to use the following inscription:

NIKOLA TESLA
1856 - 1943
HIS NAME MARKS AN EPOCH
IN A SINGLE BURST OF
INVENTION HE CREATED THE
POLYPHASE ALTERNATING CURRENT SYSTEM OF MOTORS AND
GENERATORS THAT POWERS OUR
WORLD. HE GAVE US EVERY
ESSENTIAL OF RADIO, AND LAID
THE FOUNDATION FOR MUCH OF
TODAY'S TECHNOLOGY.

There will probably be several readers who might wish that I had said something else on this plaque. Nevertheless, these were Tesla's greatest achievements.

Placing the Bust

My youngest son told me about a band in California named TESLA that might be interested in contributing to our campaign. I wrote to them. In a few weeks their drummer and a guitar player responded personally with a check for $1,800. In addition, we wrote to dozens of CEOs of power companies and large corporations. Many responded with checks of $50 to $100. It seemed we were making real progress because many people in high positions were sympathetic to our message.

As we struggled deciding where to place our bust, someone suggested the Henry Ford Museum in Dearborn. They have an entire section of their museum devoted to the history of electrical science. We believed they would welcome with open arms a bust of this caliber for their display.

When I drove to Dearborn to confer with their head curator, I showed him a large full-color photograph of our bust and told him our story about how it came into being. Then, on behalf of my students, I offered the bust fully expecting that he would accept it. After all, the bust was magnificent and had an appraised value of $6,000. I was struck dumb when he refused our offer. It was simply beyond my comprehension that such a prestigious museum would refuse to accept and display the bust of America's greatest inventor in electrical science. As I left the building, admittedly dazed, I noticed a huge model of the Statue of Liberty featuring an Edison display. The theme was a celebration of Edison for making possible the electrical energy needed to illuminate our national monument. It was apparent AC power was celebrated rather than Edison's incandescent lamp.

As I walked out the door I looked back, and there above the entryway I saw an inscription I had apparently missed when I first entered. It read, "The Edison Institute." Now everything suddenly fit into place. Edison and Ford were close friends, and it was reasonable to expect the Ford company would continue to celebrate Edison's name. I thought, "There must certainly be other museums that would not have this kind of bias," so I visited the Chicago Museum of Science and Industry. I concluded it was nothing more than a haven for commercial displays—certainly nothing to compare with, say, the Toronto Science Museum. Canada was out of the question though because we wanted to keep the bust in this country.

Finally someone suggested we go to the top—to the most august institution of them all, the Smithsonian. It is the one place in our country where only the greatest have their places in history preserved forever...men such as George Washington, Thomas Jefferson and Joseph Henry. Certainly their officials would understand and appreciate Tesla's stature.

"It was simply beyond my comprehension that such a prestigious museum would refuse to accept and display the bust of America's greatest inventor in electrical science."

I reasoned they probably had already recognized Tesla's accomplishments and might have a bust, so I decided to travel to Washington in 1988 to visit the Smithsonian's National Museum of American History. I had visions of seeing nothing but the grandest of sculptures and extensive displays. Upon arriving I discovered that the electrical section was closed for renovation. When I explained to officials my purpose of coming to Washington, I was treated to a personal tour of their archives by none other than the curator's assistant. He gave me a book describing their displays, but I was also able to see a part of the museum that was not open to the public. There were numerous busts, but none were so great as to make our bust seem inferior. Therefore, I saw no reason why the museum could possibly refuse it. I returned to Ann Arbor with the book under my arm and feeling as if my trip had been a success. All that remained was to make our formal offer and our project would be finished.

When the bust was finished, one of my students volunteered to write to the museum. In a few days we received a reply from Dr. Bernard S. Finn, curator of the Division of Electricity and Modern Physics. He did not want the bust! My students were devastated, and again I was struck dumb. He explained they 'almost never collect busts in their Division.' Later, a friend who had visited the museum and taken photographs sent me one revealing that Dr. Finn was displaying Edison's bust next to Tesla's first AC motor/generator. Tesla's U.S. patent number appeared on the motor/generator, but the display was arranged in such a way as to give credit to Edison. Needless to say, I was astonished.

Further investigation revealed we were not the first group pressuring Dr. Finn to recognize Tesla. Several years earlier a congressman had chided Finn to create a Tesla display. The display prepared by Dr. Finn consisted of a small glass showcase housing a few insignificant personal artifacts. The showcase was placed in a darkened hallway next to the men's room, while the main gallery was devoted to an elaborate Edison display.

By this time I had thoroughly read Dr. Finn's book, *Lighting a Revolution*, given to me by Finn's assistant when I visited the museum. My first *73 Amateur Radio Today* article (December 1995) describes Finn's section titled, "The Beginning of the Electrical Age," naming 43 contributors to the science of electricity. Tesla's name was omitted! This was particularly disturbing because, in describing the Niagara Falls Power Project, Dr. Finn alluded to Edison's genius that made the Niagara project possible: "When the Niagara Falls power station began operating in 1895, it signaled the final major act in the revolutionary drama that began in Menlo Park in the fall of 1879." In other words, in 1879 Edison invented DC electricity! Then, in 1895, he invented AC and harnessed Niagara Falls! The historical truth of this episode is that Edison fought the rise of AC and played no role whatever in the Niagara Falls power project. An acknowledgment on the inside of the book revealed that its funding was made

possible by the Thomas Alva Edison Foundation. I wondered if Dr. Finn's depiction of electrical history was highly biased toward Edison because funding for the book came from the Edison Foundation?

In *Science*, Vol. 245. July - Sept. 1989. p.768. a book review titled "The Real Edison, The Making of an Inventor," by Reese V. Jenkins et al., Eds. Johns Hopkins University Press, Baltimore, 1989, carries a most revealing observation: "This volume renders untenable the popular view of Edison as a Merlinesque figure who wrestles with mysterious forces and single-handedly conjures up stunning inventions."

My daughter teaches physics and chemistry at a nearby university. I asked her to involve her physics students in my campaign. They wrote numerous letters to the secretary of the Smithsonian besieging him to accept our bust. All responses were negative because the Secretary was determined to back Finn's personal bias toward Edison, amounting to the virtual exclusion of Tesla.

One of my students suggested we make promotional T-shirts and sweatshirts to sell. We decided to put a picture of our bust on the front. My wife, who is usually not vocal, suggested we use the caption, "BUST THE SMITHSONIAN." We engaged an artist to create a seven-color likeness of Tesla including several symbolic figures representing highlights in his life for the back of the shirts. The artwork and silk-screening would be complex and we could find only one firm in Ann Arbor able to do the work. The end product was magnificent! We sold hundreds of shirts in nearly every state, the proceeds going into a charitable account for two additional busts soon to be cast.

My next move was to write to U.S. Senator Carl Levin from Michigan, asking if he could exercise some of his political clout on the Smithsonian. Several letters were exchanged, but they had no apparent effect. Then, in one final effort, Senator Levin, on July 10, 1990, stood on the floor of the U.S. Senate and delivered a scorching account of the Smithsonian's historical debacle regarding Tesla (*Congressional Record*, Vol. 136, No. 86): "...Nikola Tesla has not been granted his proper place in history. In the Smithsonian Institution, for example, Mr. Edison's inventions are justifiably well represented. However, although the museum has included Mr. Tesla's alternating current generators in their exhibit, no mention is made of Mr. Tesla. In fact, the generator is included as part of the Edison exhibit."

At this time several Michigan newspaper articles telling our story appeared in Detroit and locally. Later, an Associated Press writer put the story in newspapers throughout the country. I even received one report the article was seen in a Hong Kong newspaper. All this publicity had no effect on Smithsonian policy. However, the secretary finally promised to have Dr. Finn create a significant Tesla display in 1993. Their plan was to commemorate the hundredth anniversary of the Columbian Exposition in Chicago. This was the first World's Fair, brilliantly lit by electricity—the same AC that powers the world today, made practical by Tesla's genius.

"If, on the other hand, a club or perhaps some students read this story and want to become involved, either by radio or on the Internet, they could make their feelings known."

I sensed that the secretary was only buying time and that some excuse would be found not to give Tesla his due. It was not long before my apprehension became reality. Dr. Finn was relying on obtaining a few Tesla artifacts held in a Yugoslavian museum. Soon thereafter the war in Yugoslavia erupted. Now Dr. Finn uses the war as an excuse not to create a Tesla display. The Yugoslavian museum items he deems so important for his proposed display are only insignificant artifacts...a suit of clothing, a cane, a pair of shoes, a suitcase, etc. Obviously, the public would not relate these items to Tesla's greatest contributions—his rotating magnetic field principle and his basic four-tuned circuit forming the necessary element of radio. Dr. Finn's plan is to explain Tesla as an eccentric loner who remained outside the arena of mainstream academe and industry. Would not science history be better served if he highlighted and paid tribute to Tesla's greatest contributions? These fundamental discoveries serve as the foundation for our two most important industries—power and communication.

It was Hans Christian Oersted discovering electromagnetism in 1820, followed by Michael Faraday making the first electromagnetic generator in 1831, that really opened the age of electric power. Tesla's rotating magnetic field principle indeed "signaled the final major act in the revolutionary drama"... but that drama began with Oersted and Faraday, not with Edison at Menlo Park!

How to Protest

The Smithsonian was criticized severely recently, and rightly so, by veterans groups and others for their wrongful depiction of history regarding the bombing of Hiroshima and Nagasaki. The outcry was so loud that Smithsonian officials had to modify their Enola Gay display. I see little difference in the historical bias the Smithsonian shows against Tesla and the nonsensical bias they preferred regarding the Hiroshima and Nagasaki bombing. Of course the main difference in these disputes is that Tesla does not have large segments of the general public complaining to Smithsonian officials.

When Wayne Green asked me to write a second article for *73 Amateur Radio Today*, I wondered who in the amateur community really cares anything about Tesla or the Smithsonian's depiction of electrical history. I also wondered what I might expect to accomplish by writing a second article. The logical answer to that question is, "probably nothing," because amateurs comprise a small group...certainly not even close to the size of a national veterans group. Therefore, I cannot expect a large outcry of protest to the Smithsonian. If, on the other hand, a club or perhaps some students read this story and want to become involved, either by radio or on the Internet, they could make their feelings known.

Unfortunately, the Smithsonian is a political organization, much the same as many other groups in Washington—they blow in the direction of the wind. I believe the wind has been blowing for too long in Edison's direction, particularly in regard to his entrepreneurial experiment with DC power. I want to see credit given where credit is due...to Tesla for his polyphase AC system...the system that works.

The History of Technology faction that has emerged in recent years has subverted our national museum and converted it into an advertising medium promoting specific industries that support them financially. Also, the group that has assumed power at the Smithsonian is methodically dismantling and converting our national museum into an instrument for social change. What was once a tribute to America is gradually

Continued on page 30

Tesla:
Continued from page 28

being transformed into an assault on American history. I strongly suspect these issues were not even imagined by Mr. James Smithson, a genteel and erudite Englishman, when he bequeathed his estate to the government of the United States to establish the Smithsonian "for the increase and diffusion of knowledge." Smithson was a scientist and man of letters, not a social activist. He undoubtedly envisioned a museum that celebrated creativity rather than entrepreneurship, and tasteful displays depicting an accurate account of our society's accomplishments rather than focusing on its problems.

One way of changing the direction that the Smithsonian has been heading is by voicing strong opposition to its head: Mr. Ira Michael Heyman, Secretary, Smithsonian Institution, Washington, D.C. 20560

Much of the change in focus at the Smithsonian started with its former head, Secretary Robert McCormick Adams who retired in 1994. It appears that Secretary Heyman intends to continue the course started by Mr. Adams. If any readers feel obliged to write to Secretary Heyman, I would be pleased to receive a copy of your letter.

Telephone Flasher

Don't miss any more phone calls.

Chet Garrison W6ZZB
3544 E. Dayton Avenue
Fresno CA 93726

So, you're at your rig with the ear phones on and working some good DX when the telephone rings. You don't hear it and it is your wife at the beauty parlor and she needs a ride home. Boy! Are you in trouble!

It you had built the circuit In this article, it could have saved you from the dog house. This circuit, when connected to AC and the telephone line, will flash a light every time the phone rings. Of course you must have a phone outlet in your shack. Doesn't everyone?

The circuit is dirt simple and can be hard-wired or you can use the PC board accompanying this article. All the parts can be mounted on a 2" square circuit board and will fit into a "wall transformer" case from which the transformer has been removed. However, I'll leave the cabinet or enclosure choice to you.

In my case, I chose a 48-volt SPDT relay because the ringing voltage is approximately 48 to 50 volts.

Parts list:

Relay 48 volt SPDT Part # R22-5D16-48, NTE Electronics Inc. (may be ordered from Radio Shack)
C1 1 µF, 200 volt, non-polarized
C2 10 µF, 50 volt
Rectifier Full Wave Bridge RS # 276 1152

Miscellaneous AC oulets and plug and telephone wire with the proper termination.

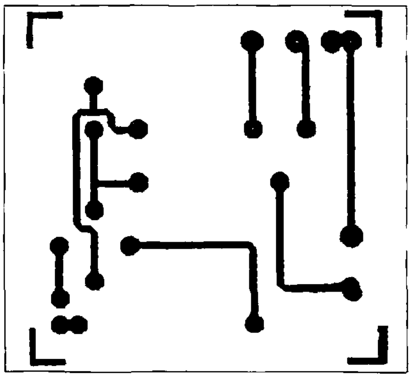

Fig. 1. The foil side of the board.

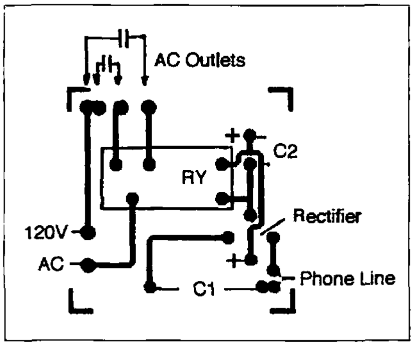

Fig. 2. The component side of the board, showing parts placement.

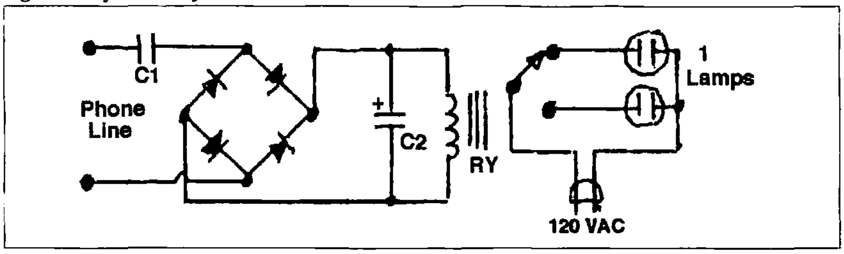

Fig. 3. The circuit diagram.

Free Electricity

Is it worth the price?

Mike Bryce WB8VGE
2225 Mayflower Ave. NW
Massillon OH 44647

Photovoltaics, electricity from the sun, is the ultimate source of energy. It's a clean, nonrotating, renewable source of electricity. Hams have been taking advantage of solar energy since the first surplus cells appeared on the market.

I have been using the sun's energy since 1978. I've designed thousands of systems worldwide through my SunLight Energy Systems company. However, my personal favorite just happens to be located a few miles from my home. It's the home of Clyde "Chuck" Davis WA8YGU. Chuck, like me, has always been interested in solar power. Pushed by the ever increasing cost of electricity from the power company, environmental concerns, and self-sufficiency, he contacted me. Let's take a closer look at his "system" and how it came to be.

Design Goals

Chuck wanted a system that would power his entire home. Some of the loads included were the furnace, washer/dryer, refrigeration, and a small air conditioning unit. Chuck also operates a 24-hour landline-based BBS. Several computer calculations showed that the amount of energy required per day was about 50 kW/hours. At the current cost of grid supplied electricity, Chuck's average monthly electric bills were peaking about $160 a month.

Since most of the loads specified were AC, all loads would operate from a DC-to-AC sine wave inverter. A sine wave inverter was chosen since several of the AC loads would operate unsatisfactorily under the modified square wave some inverters use.

The Solar Panels

Most hams would look for the cheapest solar panels. In a design like this one, there were several other factors that had to be included. Aside from the actual cost of the panels, we had to take into account the required panel mounting structures and the labor required to install the panels. Smaller wattage panels, while less expensive, require more mounting space for a given amount of power. The added cost of interconnecting wires and cables also had to be taken into account.

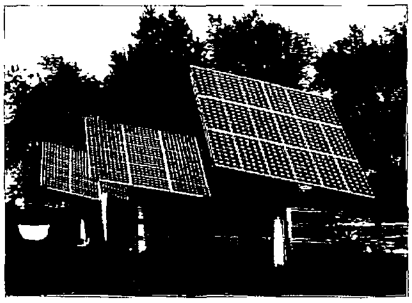

Photo A. The three arrays keep the battery bank fully charged, providing all the power needed for the home and hamshack.

On my first rough draft, I suggested two types of panels. The first was the Solarex MSX-64. This polycrystalline panel produces 64 watts under standard test conditions. Its large extra-heavy frame makes it an ideal unit to use in our local climate. It uses standard 1/2-inch electrical conduit, making the interconnection between modules neat and easy. And it comes with a 20-year warranty against power loss.

The second module I recommended was the Siemens ProCharger PC4-JF. It's made of single-crystal cells and produces 75 watts under standard test conditions. As with the Solarex panel, the PC4-JF will also accept standard electrical connections via its junction box. It also has a built-in bypass diode. This is different from a blocking diode in that a bypass diode will shunt current around a shaded panel, protecting it from damage. It has a 10-year warranty against power loss, and costs less than the Solarex panels.

Chuck decided to go with the Siemens modules. Given an array of 18 panels, the difference between the two would be a total of 190 watts! That extra 11 watts each panel produces would equal more than two MSX-64 panels, when configured in an 18-panel array. With a planned three arrays, that's an extra nine panels at a cost of zero dollars.

Naturally, right after the first PC4-JF had arrived, Solarex announced a new, higher-power version in its MSX "MEGA" series. Had the new MSX-83 (83 watts vs. the 75 watts of the PC4-JF) been available, then the MSX-83 would have been our choice.

There are 18 panels in each array. The panels are wired in series to provide a 24-volt system. The system voltage was determined by the inverter, as I'll explain later on.

Each subset of 24 volts is wired in parallel with the rest of the array. So, of the 18 panels, 9 are in series and 9 are in parallel. Each array then produces a total of 918 peak watts. That breaks down to 27 amps at 34 volts. The entire system produces just short of 3kWpa (peak array).

All three arrays are wired the same. The power from each array is combined in junction boxes at the base of arrays #1 and #2. From the junction box, there are four runs of four-ought weld cable routing the power into the battery storage area. Along with the power cables, several runs of "data" wires were also pulled though the 4-inch underground conduit. In the future, these data wires will connect to different sensors, providing such data collection as array cell temperature, wind direction and speed, as well as individual array current.

Each set of 18 panels is mounted on a dual-axis solar tracking mount. Dual-axis means the mount will track the sun

from east to west and north to south, all at the same time. At dusk, the "trackers" automatically reset back to the east, awaiting the sun's return the next morning. Each tracker is driven by two small electric motors.

A small battery operates the motors at night so the array is pointing toward the east.

Controlling the Power

Under a bright, clear sky the three arrays will produce over 118 amps continuously. Peak current has been noted at over 125 amps. A Heliotrope General CC-120E was used to control the current to protect the batteries.

This controller is state-of-the art in power MOSFET design. Using PWM (pulse width modulation), the power MOSFETs keep the battery bank from being damaged by overcharging. Although the CC-120E is specified for 120 amps, the first unit did not survive. After consulting with Heliotrope General, we decided to add additional heat sinking to the controller. This heat sink consists of a half-inch thick aluminum plate about four feet square. In addition to the aluminum plate, several sections of a large extruded heat sink were also attached to the plate.

The CC-120E has an internal cooling fan controlled by the temperature of the blocking diodes. The fan will run when the case temperature reaches 100°F. At no time has the automatic thermal shutdown stopped the CC-120E.

Battery Storage

We used good ol' lead-acid batteries, wired in a 24-volt system. The bank consists of 24 6V golf-cart batteries. Each battery has a capacity of 220 amp/hrs, so the battery storage bank has the capacity of 1320 amp/hrs at a 20-hour rate of discharge.

Loads

A Trace 2420 sine wave inverter supplies AC to all of the loads. So far, there has not been any load that the Trace has not been able to handle. This includes a deep well pump and various refrigeration units. The Trace has an internal DC charger, but this feature is not being used. With automatic shutdown from everything from a low battery to an overtemp condition, the Trace has been working without a glitch since day one. It has also managed to survive several very close lightning strikes, when it would shut down, wait a few minutes and then restart.

The Trace inverter, at the time the system was being designed, was available only for 24 volts. It is now available for 48 volts. Had that unit been on the market, I would have chosen it, which would have reduced the cost of the welding cable used to bring in the power from the arrays.

System performance

The system has been online for over a year and has produced over 4 *million* kW hours.

Two of the dual-axis trackers failed, but they were replaced by the manufacturer. Since the replacements were installed we haven't noted any problems with the trackers.

With the dual-axis trackers, in the summer months the array-to-load ratio is over 10:1. This means there is slightly more than twice the array capacity than load demand. The battery bank can be depleted to 50 percent at night and be fully recharged by the middle of the next day.

During the winter months, the array-to-load ratio is a break-even 1:1. The battery storage is sized a bit too small to operate all the loads during the winter. Increasing the battery size would provide greater running time, but it would also increase the time required to fully recharge. In the summer, Ohio averages over seven hours of sun per day when using the dual-axis trackers. However, in January we average only three hours.

Things I Would Change

My original design did not specify the dual-axis trackers. I had specified a seasonal adjustable top-of-pole mount. In this location of Ohio, the trackers will not produce much additional power during the worst part of the year.

In January, the sun sits too low in the south for the trackers to do much good, but Chuck had to have them.

I had originally specified Trojan L-16 batteries for the battery bank. Chuck decided against them from two reasons. First, new 6-volt lead/acid golf-cart batteries were available for $38 each from a local source. The L-16s, on the other hand, were $190 each. The L-16 is also 6 volts.

The golf-cart battery weighs about 70 pounds. The L-16 is 120 pounds. Since the batteries are in the basement, each battery would have had to be carried down by hand. Of course, when a battery went bad, it would have to be carried up as well.

Why not use a different battery? Well, ideally, a forklift battery would have been my first choice. The problem is, you need a forklift to move one! We considered NiCd batteries, but their cost put them out of the question. When the current batteries need replacing, we may use large 2-volt sealed lead-acid batteries.

The Bottom Line

What is the payback period? Well, the whole system cost about $35,000. Had Chuck gone with the top-of-pole mount instead of the dual trackers, he would have saved $7,500. And using L-16s instead of the golf-cart batteries would have cost him about $2,000 more.

As for the payback period? Well, Chuck will more than likely never see the system pay for itself. However, several months after the first array went online, Chuck's electric bill dropped so much Ohio Edison sent out a troubleshooting crew.

Still, not counting any maintenance of battery replacements, Chuck is looking at around 15 years before he breaks even.

Caveats

Electrical space heating and refrigeration are two loads that should be run on a source of energy besides PV. In this case, Chuck is running both air

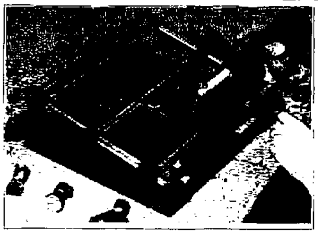
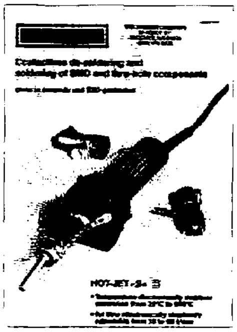
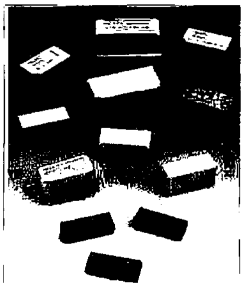
NEW PRODUCTS





Leister/Malcom

Leister sells hot air equipment for welding, drying, curing, shrinking, desoldering, and soldering. The leaflet includes color photos of the new Leister Hot-Jet "S", and is available from The Malcom Company. To find out more, circle Reader Service No. 201

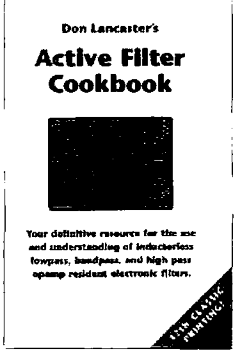


"World Class" Relays

GEM Electronics, Inc.

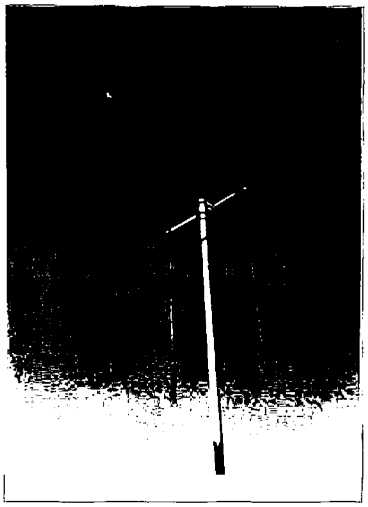
Need a Data Sheet on a particular relay, or some general information on relays? GEM Electronics can help you with their line of Meder Electronic Relays. Circle Reader Service No. 203.

Active Filter Cookbook



Microcomputer guru Don Lancaster has been at it again with this 17th edition. So what's an active filter? It's a combo of op-amps, resistors, and capacitors which replace traditional bandpass and high-pass filters with something smaller, less expensive, easier tuning, and simple in design. The book runs 240 pages and is packed with enough application circuits to keep a builder happy for months. It's $28.50 via better book stores or from Synergetics Press, Box 809G, Thatcher AZ 85552. Circle Reader Service No. 208.

Cubex Antenna Company



The CUBEX Antenna Company has produced the "BUMBLEBEE" 6m 2-element quad antenna. It is all fiberglass with a heavy duty aluminum mast to boom coupler. The antenna is fed directly with 52-ohm coax and features the exclusive CUBEX tuning block that allows the antenna resonance point to be adjusted so that the entire 6m band can be used without completely changing the wire elements. The antenna comes with the driven element pre-marked for a resonant frequency of 50.4 MHz, giving the antenna a bandwidth of 1.5 MHz at an SWR of less than 1.7 to 1. The antenna can be rotated for horizontal or vertical polarization, and has a boom length of 27 inches. The best feature is the price of $69.95 F.O.B. BREA CA. PLUS $12 S & H. Circle Reader Service No. 202.

NCG COMET

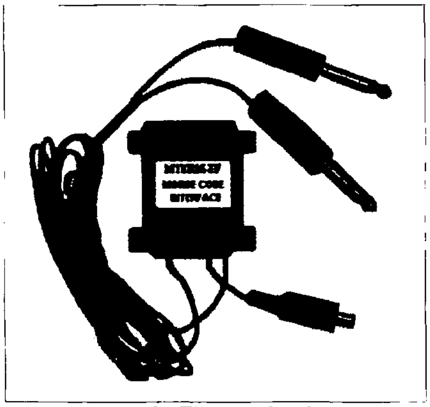
The COMET "Quick-Disconnect" Mobile Antenna Mount, Model CQ-5M consists of two separate sections: A trunk-mount base that is attached to the trunk edge with four set screws, and an antenna-mount base that fits inside the trunk-mount base. Sliding a lever wedges the antenna-mount base securely in place. To remove the antenna, simply slide the lever to unlock. The antenna can then be placed inside the trunk. Comet's 17-foot deluxe coax cable assembly is included. The first 12 inches of coax is RG-188A/U style, allowing easy entry into the trunk without causing cable damage or starting a water leak. The coax balance is double shielded, low loss, with gold-plated connectors.

Two offset washers rotate around the antenna connector to adjust the antenna to the vertical position. The bottom of the trunk mount base is rubber-coated to prevent paint damage. It has a wide foot print to support large antennas. Two versions are available: CQ-5M has an SO-239 antenna connector, and a PL-259 transceiver connector. CQ-5N has N-type connectors. Contact your local or favorite amateur dealer. List price is $66.95. For more info on COMET products, and a complete catalog, contact the NCG Company at (800) 962-2611, or circle Reader Service No. 204.

MCM Electronics

MCM Electronics, an industry leader in the distribution of consumer electronic repair parts and accessories, is introducing their *free* catalog, No. 36.

The catalog contains over 2,700 new items, including project accessories, semiconductors, connectors, test equipment, computer products, audio, TV, VCR, and appliance repair parts. This catalog also introduces LAN cable test products from Paladin and Triplett, quality crimping tools from Sargent, and many other new items for the electronics service technician. Catalog 36 also announces permanent price reductions on semiconductors, video heads, flybacks, motors, and other items used in consumer electronics service. Circle Reader Service No. 207.



Dynamic Electronics Inc.

Dynamic Electronics Inc. is pleased to announce a new Morse Code Computer Interface that allows sending and receiving the International Morse Code with an IBM-compatible computer. The interface electronics is contained in a DB-25 housing which can be connected to any COM port on an IBM Compatible Computer. An adapter can be used for 9-pin COM ports. A 1/4" plug is included for the "phone" jack and a 1/4" stereo plug is included for the "key" jack of a transceiver. A stereo-mono adapter (not included) can be used for 1/4" mono "key" jacks. A 900-Hz audio filter with a noise subtracter is included. An RCA-type phono jack is available for connecting the processed CW to the high impedance input of an audio amplifier. The speed is automatically tracked on receive. The code is converted to ASCII characters and displayed on the screen. The station can be left unattended and messages can be saved to a disk file when a call sign match is received. A Call Alert feature will allow the computer to sound an alarm when a call sign match is received.

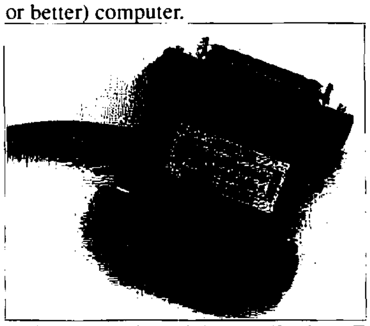
Transmit features include a type-ahead keyboard buffer, and the options of sending from any of the 8 preprogrammed messages, or from a disk file. The transmit speed can be varied from 5 to 100 wpm. A message can be automatically sent at a future time without the operator being present.

Software is supplied on both 5.25" and 3.5" diskettes. The cost is only $79.95 plus $3 shipping. Payment can be made by checks, VISA, or Master Card. For more information, circle Reader Service No. 206.

Advanced Electronic Applications, Inc.

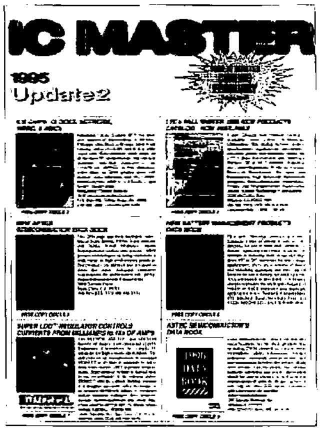
AEA recently introduced the new AEA ACARS package for receiving aircraft digital communications. AEA ACARS is a package containing a small demodulator cable and DOS computer software that, when attached to a scanner or receiver, lets you decode the digital communications taking place between ground stations and aircraft. ACARS is a digital data link system designed to enhance air-ground-air communications. If you are near a major airport, you can even monitor both air-to-ground and ground-to-air digital communications.

All you need is AEA ACARS, a VHF receiver or scanner capable of covering 129-132 MHz AM, and an IBM-compatible (386 or better) computer.



There are three versions of AEA ACARS: (1) the entire package which includes the demodulator, software, and detailed manual; (2) the AEA FAX ACARS Upgrade—so AEA FAX owners can get the software-only version of AEA ACARS to use with their current demodulator; (3) the AEA ACARS 900 package. AEA PK-900 owners already have the hardware built into their data controllers. All they need is this special software-only version of ACARS designed to work with the PK-900. AEA ACARS is available from your favorite amateur radio equipment dealers. For more information on AEA ACARS, call AEA's literature request line at (800) 432-8873, or fax requests to (206) 775-2340. Advanced Electronic Applications, Inc., P.O. Box C2160, Lynnwood WA 98036. Or circle Reader Service No. 205.

IC Master



The new IC Master Catalog is coming out in February on paper, and on CD in March. With over 120,000 different *kinds* of integrated circuits sold by way more than 250 manufacturers around the world, you need something to help you stay oriented. IC Master is a comprehensive reference full of product information. The CD comes in DOS and Windows versions (sorry, Mac users). The Windows version even includes packaging and pin-out information.

The new catalog will have info on more than 20,000 first-time-listed devices, including over 460 new op-amps, 6,000 new listings for memory, 2,000 new digital, and 500 new processors/controllers.

As valuable as the above information is, you can also order several smaller catalogs and other literature from manufacturers for free from IC Master, such as the Datel DC/DC Converters Catalog, the Astec Semiconductor's Data Book, and the Semtech Battery Power Management Products Catalog.

Order before the January 31st deadline and you can get the 1996 IC Master CD-ROM PLUS for $210, which is $25 off the reduced regular subscription price. Circle Reader Service No. 209.

Add-On 2 Meter Receiver Selectivity

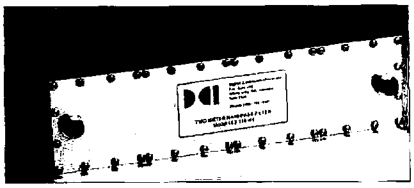

Photo A. The DCI-146-4H 2 meter bandpass filter.

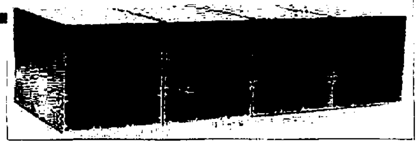

Photo B. The interior of the unit.

Bill Clarke WA4BLC
764 Alta-Voor Road
Altamont, NY 12009

With the proliferation of radio signal producers, both those that are supposed to radiate signals and those that do anyway. 2 meters has become a chore to listen to in many RF-dense areas.

An RF-dense area can be a metropolitan area with loads of pagers, commercial repeater services, cable TV, and/or computers. It can also be a rural mountain, loaded with broadcasters and leased repeater services.

Types of Interference

Nearly everyone using 2 meters has experienced some form of interference at one time or another. Generally, the interference experienced will consist of:

Signal suppressing or blocking—caused by a strong RF signal which desensitizes the receiver, making it incapable of receiving the desired signal. Such signals are from transmitters on "near the 2 meter band" frequencies. A good example is the large number of paging systems located just above the two meter band.

Sidelobe interference—occurs when a signal on a nearby frequency (not within the receiver's passband) bleeds into the region of the passband and blocks the receiver.

Intermodulation—usually referred to as intermod or IMD, is caused by two or more signals from outside the receiver's passband mixing internally within the receiver, then blocking or otherwise interfering with the receiver's operation.

Using a filter such as the DCI-146-4H can reduce instances of these types of interference, often totally eliminating them.

The DCI-146-4H filter consists of four helical resonators mounted in a very solid chassis with two coaxial cable connectors. Helical resonators can be thought of as very high-Q RF circuits, passing only a very narrow band of signals. In the case of this particular unit, that passband range is 144 to 148 MHz. The skirts are quite steep, as shown in the chart, and provide up to -62 dBm reduction in signals outside of the filter's passband. The DCI filter is passive and requires no outside power source. You receive and transmit through it with power levels up to 200 watts.

This type of filter (very narrow passband) allows the receiver to be undisturbed by most out-of-band signals, providing for increased sensitivity and clearer reception.

Specifications

Passband:	144 to 148 MHz
Passband loss:	<1 dB
Selectivity:	-62 dB at 136 MHz
	-50 dB at 156 MHz
Power rating:	200 watts
VSWR:	1.5:1
Dimensions:	12 x 3 x 5 inches
Weight:	2 lbs. 11 oz.

The Test

To give the DCI 2 Meter Bandpass Filter a real-world operational test, I took the unit to a nearby mountaintop where there is an abundance of commercial FM and TV broadcast transmitters and various commercial repeater systems (on all bands). In this particular area, the S-meter (which is an LED bar graph on my 2 meter transceiver) dances all over, and, although the squelch is not broken at all times, the receiver is quite desensed. Even relatively strong stations cannot be heard well.

The test results on the mountain were quite positive. Only the slightest indication of intruding signals on the S-meter could be seen, and that was very sporadic. No noticeable degradation of signals was noticed, even when working distant repeaters and weak simplex stations. A quick removal of the filter gave instant proof that the filter really works, as without the filter the S-meter came alive and the distant stations were lost.

On the test bench I found that the unit's passband was a very close approximation to that indicated in the manufacturer's literature. Due to the very steep skirts of the DCI-146-4H, I doubt CAP and MARS users could use the filter. The SWR seen during transmit rises very quickly as you move out of band. During static testing I used a commercial dummy load and input power of 50 watts, although the filter is rated at 200 watts. Of note: No heating of the filter was observed during testing.

As a final operational test, I went near the transmitter site of a paging company that operates just above the 2 meter band. Using an HT connected to my mobile 2 meter antenna, I found the receiver to be blocked a large percentage of the time and the S-meter dancing a jig. I connected the DCI-146-4H into the antenna line and the problem ceased, with only a small amount of S-meter jumping noted. This type of setup should help the commuting ham using a handheld in RF crowded areas.

Comments

Installation is simple: Just put the DCI-146-4H in the antenna line by using

a short jumper cable. The filter will do its job without any operator control—install and forget. Due to its size, you might wish to remotely mount the filter—just keep in mind that you want a reasonably short patch line from the rig to the filter. Firewall mounting appears to be practical on some vehicles (where there is space). Other choices are under a seat, in the trunk, etc. There are no mounting holes on the unit, and *do not drill any!* My recommendation for mounting is:

1. Use plumber's strap over the unit and fasten the strap to the mounting surface with sheet metal screws.

2. Attach the unit to a surface with silicon glue.

The DCI 2 meter filter makes up for the wide-open front ends found on most 2 meter transceivers (wide-open meaning the receivers easily receive 135 through 170 MHz). When using the DCI-146-4H, effective receiver sensitivity outside the 2 meter band will be greatly reduced.

Too bad someone cannot design a filter that will remove all the computer hash heard around shopping centers, bands, and the like.

Availability

The DCI line of helical resonator filters is available at most ham radio stores and from DCI Digital Communications, Inc.

Note that DCI Digital Communications also produces filters for the 220 and 440 amateur bands. Commercial filters areavailable—call for specific applications.

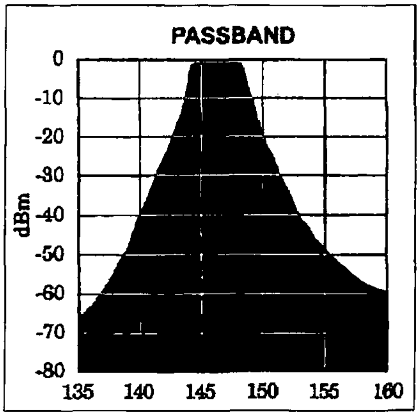

Fig. 1. Graph of the unit's passband.

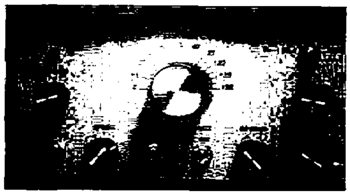
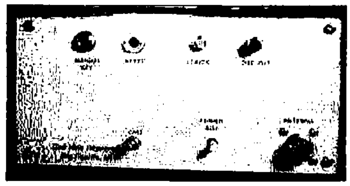
Oak Hills OHR-400 4 Band QRP Kit

Ah! the joys of building!



Front OHR-400



Back OHR-400

Jeff M. Gold AC4HF
1751 Dry Creek Road
Cookeville TN 38501

I had not built a kit in awhile and my personality had started to deteriorate proportionally. I seemed to have forgotten how therapeutic the building process is for me. I started to rationalize that I have built one of everything and that placing components on a board was just not as much fun as it used to be. I couldn't resist the temptation when I heard about the Oak Hills fourbander. Four bands, three of my favorite (20, 30, 40 meters) and one that I need to spend some more time on (80 meters) anyway. So I told the XYL I needed some money for counseling, and sent off for the kit.

I anxiously awaited the arrival of the kit. My children are now pretty well grown up, no grandchildren in the near future, so I guess this is the closest I can come for the time being to an anxiously awaited arrival. I got home from work on Friday afternoon. This was a real big weekend for me. Three days off and the weather was supposed to be nice for the first time in eight weeks. What more could I ask for? I came home from work and there was the box from UPS that I had been waiting for. Having significantly matured (if you can believe this one), I went and changed out of my work clothes before taking the prize to my workshop to unpack.

The first thing I noticed when opening the box was how carefully and professionally it was packed. All of the little components were packed inside the case and sealed so that you don't accidentally throw them away. There are three printed circuit boards, not counting the optional keyer. The boards are the absolute best I have ever come across (I have seen some as good, but none better). They are solder masked and have a terrific silk-screening. There is *no* question which parts go where. The receiver board has the parts fairly well packed, so the very high quality silk-screening is a definite plus.

Another thing I have noted is that Dick from Oak Hills really listens to his customers. This is evident with the documentation. The documentation comes in several sections which are individually stapled. The printing is top quality and easy for even my old eyes to read without the need for those new reading glasses (so in essence the kit makes me feel a little younger). The first section of the documentation is the Assembly Instructions. Oak Hills has a couple of pages on things you need to be aware of to make your building experience more pleasant and more likely to have you succeed with the project. The instructions are step by step, but not in the hand-holding "put this part R3 in hole in section 1A" way Heath used to do it. I really appreciate the clearness of instructions and not having to read and reread something many times to figure out if what I read and thought I understood is what the writer meant for me to understand.

Working with technical writing in the computer field, I realize how hard it is to write good instructions. Oak Hills also has started to include very professional diagrams for the final assembly in with the documentation. There are separate sections for each board that list all the components, a schematic, and an excellent, enlarged overlay. One of my main criteria for pleasure in building a kit is knowing what the author really means when building instructions are given. I feel it takes some of the therapeutic value away from the project when there is ambiguity in any of the steps.

The parts for each board come separately wrapped. This is another example of Oak Hills' listening to the customers. For each board the parts are separated by type, such as resistors and capacitors. I usually hate the first stage of building, which involves the sorting out of the parts and checking to make sure that they are all there. It used to take a great deal of time to separate and label the parts. Now I use little plastic parts bins and dump the resistors in one, the capacitors in another, and so on. I find it fairly easy to then use my magnifying glass (even Oak Hills couldn't solve this problem for me) to make sure I get the right part when I start stuffing the board. I find that after a few minutes of separating out the parts and documentation I can get into the project fairly quickly.

The cabinet for the kit is also very high quality and has a great paint job. The panels are beautifully screened. I believe them to be as good in quality as the major transceiver manufacturers' cabinets.

There are two distinct and equally important aspects of a kit for me: how much fun it is to build and how much I like to operate it when it is done. I have found that there are sufficient variables involved in implementing a kit design so that even the best designs may not work as they should when they are built. Some rigs are just more fun to operate than others. I finally took some time recently to ponder this aspect of my building experiences. I have built about every kit on the market in the last three years. I can pinpoint exactly what constitutes a pleasurable building experience for me. The parts in the kit have to be high quality;

the documentation has to be clear, tested and revised to eliminate errors, with no ambiguity at all; the printed circuit board needs to be high quality and clearly screened; and there should be separate parts lists by circuit board, with a clear enlarged parts overlay.

The fun-to-operate part is much more nebulous. This aspect is very personal. I have come up with a scientific method to determine this aspect. It is really quite easy. I have many rigs on my workbench. The number and type seem to change constantly. I find there are some rigs that I just keep using after the initial testing and evaluating. The reason for this is that they seem to me to work better and are more fun to operate. I put my Norcal 40 in this category, as well as the Oak Hills kits I have built. I think it is pretty amazing that small companies like Wilderness Radio and Oak Hills can put out such high-quality kits. They work very well as long as they are assembled properly.

Building

I found no unwanted surprises while building the kit. I built up the three boards and put in the optional iambic keyer. All went together quickly, even though I checked my work very carefully to make sure the correct parts were in the proper places on the printed circuit board and also checked all of my soldering joints with a magnifying glass. It can take quite a few hours to trace problems such as diodes or electrolytic capacitors being put in the wrong direction, or having the wrong values of resistors or capacitors placed on the board. It is much more economical and pleasurable to take a few extra seconds for each part and verify that they do indeed belong at a particular location. The board was a pleasure to solder. The plated through-holes are very easy to solder and make for strong connections. These also complicate unsoldering, so make sure you have the right parts in the right holes! If you should make a mistake (most of us do), I recommend a good quality solder sucker (can be purchased at Radio Shack) and with this board some solder wick is helpful.

Testing and Alignment

It was another Friday evening and the end of a really tough week. I am supposed to take my wife out for dinner, and my son is already at a friend's house for the weekend. Sounds like a good time for a romantic weekend...well, there was one problem. I was super-stressed from the week's events. I was in dire need of a "therapy session."

I did my mandatory chores, changed to my "play clothes" and went into the shack. I went to the bench and checked the Oak Hills Research 400 that I have put hundreds of parts into and over 50 wire connections and mounted many mechanical connectors, switches, and jacks.

The project passed the initial smoke test. I was very relieved when nothing sizzled on power up. I then took out the alignment procedures and was ready to roll. If you don't have the proper equipment or can't get it aligned, Oak Hills will align the completed rig for $65, including shipping it back to you.

The initial frequency setup went very quickly. Three of the four bands came up exactly on frequency with no adjustments necessary. Getting the fourth on frequency was a matter of adjusting a trim capacitor. It was very easy, using a frequency counter as is suggested. I switched back and forth between the bands and the oscillator for each band started with no problems. The only time-consuming adjustment involves adjusting a coil and a trim capacitor to get the correct bandwidth out of the VFO. I also like to get it so the dial reads near the real frequency. I didn't encounter any difficulties with this part.

You next adjust two coils on the oscillator board for each band for peak signal voltage as measured on a scope. I later found that I did not tune the 20 meter band coils correctly. I noticed this when I tested out the rig and found the SWR was high on 20 meters, even though I knew I was using a resonant antenna. There were two peaks for the coils, using a scope to monitor. You need to check to make sure you peak them on the correct frequency, as stated in the manual. On 20 meters I noticed that when I was peaking on the wrong frequency the power output went up to about 10 watts on my QRP wattmeter, but was right in range at the designated frequency.

Your next step is to move to the receiver board and adjust the voltage at a given point using a trimpot. That is all you do on that board at this time.

Moving on to the TX/REC board, you tune a set of coils for each band to get maximum signal output as measured on a QRP wattmeter. The two coils interact so that you need to go back and forth a few times. I noticed that 20 meters wasn't putting out a full 4–5 watts. I found that I had the power supply turned back to about 9 volts. I turned the supply up to 13 volts and the power came right up. All the bands tuned up easily and I got the correct power output on each band.

Photo A. The OHR-400 QRP kit is sensibly packaged and logically arranged.

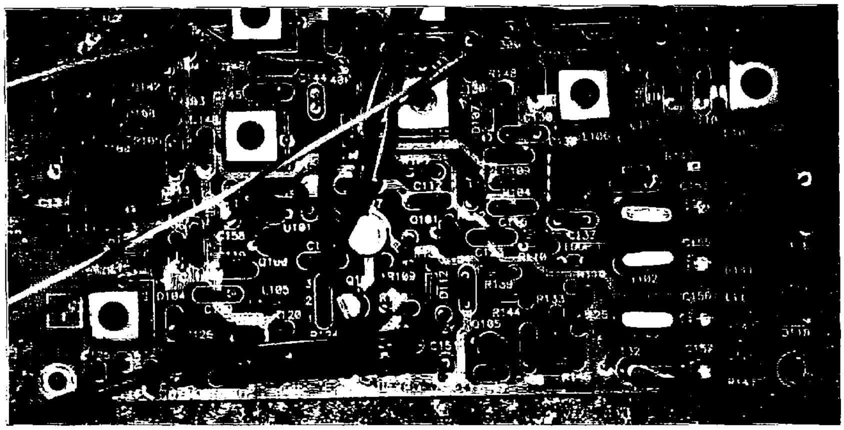


Photo B. "The boards are the absolute best I have ever come across. There is no question which parts go where."

The rest of the alignment went fairly quickly (well, I actually missed dinner and was in the doghouse for a while, but it seemed like only a few seconds). You adjust a trim capacitor on the receiver board to get the signal centered in the right place for the audio filter. The directions are quite clear and should be followed carefully. You then only need to adjust the sidetone level and one more trim capacitor to make sure that you are transmitting and receiving on the same frequency. Another transceiver is a good tool for this. If you have installed the optional keyer there is a simple adjustment for the iambic keyer weighting to get it to your preferred setting.

"I would recommend this kit very highly to hams that have a building project or two under their belt . . . "

To finish fine-tuning the receiver I decided to take it to my operating bench and hook up an antenna. I put the rig on 20 meters using a gel cell for power. As I was connecting the antenna I heard EA3DKR calling CQ. I finished connecting the antenna quickly and gave him a call. Carlos came right back to me. Who needs all those other alignments? He was a 559 and gave me a 559. My two-element quad may have helped a little. I worked an LZ1KOZ through a pileup almost immediately after working Carlos. Next I switched to 40 meters and had a long rag-chew, then back to 20 to work some more DX. I worked a Cuban station off the back of the beam.

Later in the weekend I worked UX3FW, Yura, S59AA, in Izmail, Franc SP3WYQ, George T77BL in the Republic of San Marino (it took awhile to figure out where that was), and Franc 9A2HF. I also did some rag-chewing on 30, 40, and, yes, 80. One QSO on 80 meters was an hour long. I hadn't worked 80 in quite awhile and was very pleased with how well the rig worked with 5 watts on this noisy band.

I received comments like "Your new rig sounds great," "Did you say QRP?," "Congratulations, QRP, sounds FB, Jeff!" (this guy started at 100 watts and we ended up going QRP–QRP on 80 meters), "solid copy." The last guy I talked with went on and on about how good it sounds. I worked anyone I heard, even DX that was real weak. I had nice long QSOs with no problem, on every band.

The rig was putting out about 4 watts on 20 meters and I turned the power back to 4 watts when using the other bands. Listening to the OHR-400 on a commercial transceiver, I found it had a really sweet note.

I noticed on 20 meters the SWR was just a little higher than it should be. I took out the alignment tool that was provided and adjusted the oscillator board coils for 20 meters. It brought the SWR right down to 1:1 and the rig was putting out 4 watts as it was supposed to.

I had the covers off a number of times during the weekend. This is standard operating procedure for me. It usually takes me a few times to get things set up the way I like them. I guess you could say I am a "tweak freak."

The receiver is sensitive and selective and quiet. The VFO is very stable. The audio filter and RIT work well. The QSK is fantastic, very quiet and quick. The optional Curtis keyer works fine. The audio is enough to drive a nice size Radio Shack speaker. The transmitter has a variable power control so you can work very low power if you choose to. You can adjust the power from about 5 watts on 20 and 30 to about 8 watts on 40 and 80 to close to zero.

I must say that I really enjoy operating this little rig. There is an intangible variable that I have with both the building and the operating of one of these kits. I call it the enjoyment factor. The building of this gets my top rating. A great deal of time and energy went into making it a very pleasurable experience. Does this mean it is perfect? By no means. I could spend time criticizing minor aspects, but they were minor enough that they in no way detracted from the building experience or my operating experiences. I would recommend this kit very highly to hams who have a building project or two under their belt, or even to a new builder who may want to get a little help with the alignment. There is great pleasure and satisfaction to be had when using a rig that you built yourself and that works very well.

Specifications: 80-40-30-20 Meter Bands

Receiver
- RF preamp
- Diode ring mixer
- Selectable AGC manual gain control
- 4-pole crystal ladder filter
- Selectable 4-pole audio filter
- Very stable VFO
- VFO covers 150 kHz each band
- RIT ± 1 kHz

Transmitter
- 4–5 watts all bands
- Adjustable from rear panel 0–full power
- Smooth QSK circuit
- Sidetone generator with level adjust
- Both iambic and manual key jacks

Kill Your Interference

Steve Katz WB2WIK/6
21101 Celtic Street
Chatsworth CA 91311

This subject has been so well covered over the years that I can't adequately bibliograph past articles. Yet, I still hear a dozen times a week from hams, both old and new, that they can't operate various bands (or at various times, or whatever) because they cause interference to televisions, radios, telephones, intercoms, compute modems, fax machines...you name it.

Hey, folks, this is 1996. We're all part of the information superhighway, like it or not. Electronic trinkets abound, and thousands more will follow. Who doesn't have a PC? Who doesn't have a fax machine? Who doesn't have a stereo system? And surely, who doesn't have a telephone?

In many parts of the country, cable TV servers and telephone companies are cooperating to replace copper wiring with fiber-optic cables to create interactive television and telephone services with fantastic bandwidth. These services will be more difficult to interfere with, because you can't create electromagnetic interference to an optical transmission system. But it might be many years before our homes are suitably cabled, and we'll still be using conductor-type appliances for the foreseeable future.

The solutions are amazingly simple. But many hams don't seem to want to know, or do, anything, to help themselves. If you're not a total dimwit, follow some simple advice: Interference problems can be resolved, and it's up to you to resolve them.

TVI

This is a relatively easy one. Television sets are intended to be receivers, they're just not particularly selective ones. If you and your neighbors are on "cable," and you're having TVI problems in your own home or those of your neighbors, the first order of business is to reduce the number of peripheral wires connected in the cable signal line. If you (or your neighbors) have appliances other than an approved cable TV converter box or a TV set connected, disconnect everything else (VCRs, preamps, switches, etc.) and see if the TVI persists.

The coaxial line from the cable service to the television set should be as direct as possible. Don't connect VCRs in this path! If you need to use a VCR, as most of us do, connect its input/output ports using audio cables to the television's audio input/video input and audio output/video output jacks. All the modern sets have such provisions. I see many licensed hams who have VCRs and other accessories connected to their cable lines, when it is completely unnecessary. Why convert audio and video signals to Channel 3 and feed them into the TV's tuner when you'll get far better results just plugging them directly into the audio and video amplifiers in the set, without using any RF? It doesn't make sense.

If you're on cable, do *not* use a preamp. They're a total waste of time for cable television services. The signal level from the cable should be sufficient to provide a good, strong signal to four, five, or six televisions without the need for any kind of preamplification. If you think you get "better reception" with a preamp in your cable line, either you're kidding yourself, or there's something seriously wrong with the signal level provided by your cable company. Ask them to come out and perform a measurement on your cable signal level. They all have small, hand-held devices which let them know immediately if your signal level is sufficient. If it isn't, then it is their responsibility to fix the problem, not yours.

Another warning if you're on cable: If your cable was installed more than a few years ago, it is very likely the service has deteriorated due to lack of adequate maintenance. The coaxial cables used need to be replaced every few years. They don't last forever. The connectors are not waterproof, and often fill up with water, creating a reduction in signal strength and the possibility of mixing signals with your transmitter, which in turn creates interference. Connectors should be clean and dry. You can check them yourself, if you can reach them. If you disconnect the cable from the "feed" (either above or underground), and water drips from the connector, this is a real problem that needs to be addressed. Water in an RF connector almost always indicates that water will also be present in the coaxial cable attached to it. This, too, adds attenuation and reduces signal levels. Normally, maintenance of the cable right up to the entry point of your home is your cable company's responsibility. The cable inside your home is normally your responsibility.

If you or your neighbors are not on cable, you may not have sufficient signal levels to override interference. Unless you can literally see the television transmitter's antenna from your TV antenna site, the signal will not be all that strong. Replace old, oxidized antennas with new ones, and make sure they are properly aimed. Avoid using 300-ohm "twin lead" for TV antennas! Use a 300-ohm-to-75-ohm balun instead, installed directly across the antenna terminals, and feed the antenna with high-quality, double-shielded RG59- or RG6-type CATV coaxial cable. (RG6 "quad," which has *four* shields and is "100% shielded" is an excellent choice. It's what the cable TV companies use, and it's not expensive.) If you don't have the proper crimping tool for type "F" TV connector installation, borrow or buy one. The best ones are not expensive, and are a good investment, since it seems these connectors are here to stay. If your TVI problems are from HF

(1.8-30 MHz) transmissions, try using a high-pass filter in the coaxial line to your television set, with the filter installed right at the rear panel connector of the TV, or better still, *inside* the TV between the rear panel and the tuner. Try grounding the case of this filter. If that doesn't help or makes the interference worse, remove the ground.

A word about high-pass TVI filters: These come in several "flavors," and performance is unrelated to cost in my experience. The most effective ones are really the 300-ohm "twin lead" filters, where each side of the balanced line is filtered. Unfortunately, the most effective TV transmission line is coaxial cable, not twin lead. Herein lies a dilemma, but it's an easily solved one. For stubborn cases of TVI, I've often found that using a coaxial feedline to the back of the set, followed by a 75-ohm (coax)-to-300-ohm (twin lead) balun, followed by a 300-ohm high-pass filter, followed by another 300-ohm (twin lead)-to-75-ohm (coax) balun, into the TV set's tuner, is what works best. Sure, it seems crazy to transform from coax to twin lead and then from twin lead back to coax again just to install a 300-ohm filter, but there is a method to this madness.

The problem with most 75-ohm coaxial cable high-pass filters is that while they do a splendid job rejecting interference conducted within the cable, they do absolutely zero for "common-mode" interference, which is carried on the outer conductor of the coaxial cable. Such interference conducts right past a 75-ohm coaxial filter, and enters the television set on the outer conductor (shield) of the cable alone, and can create nightmarish problems. By breaking up the cable's shield using isolation transformers and a balanced filter, such common-mode interference is thwarted by the "broken circuit" created. (P.S.—Good 75-ohm-to-300-ohm baluns, and 300-ohm high-pass filters, have almost no insertion loss, so don't worry about losing a lot of signal strength with this system. If you use good coaxial cable and a good 300-ohm filter, it won't happen.)

If the interference problems are from VHF-UHF transmissions, the best high-pass filter in the world won't help. You'll need to use a "stub," which is tuned to reject the specific frequency of the interfering signal. Such a "stub" will need to be one quarter-wavelength long, measured *in coax*, at the interfering frequency, and connected in parallel with the coaxial feedline to your TV set's tuner, as close to the tuner as possible. One quarter-wavelength *in coax* will be shorter than a real quarter-wavelength because the length needs to be corrected by the *velocity factor* of the coax used. For solid-polyethylene coaxial cable types, the velocity factor is usually 0.66; for "foam" dielectric coaxial cable types, the velocity factor is higher, typically 0.78 to 0.80 or so. Such a "stub" is easily connected to the backside of a television receiver using a "T" (or "tee") adapter having a single type F male fitting and two type F female receptacles. Such items can be picked up for a couple of dollars at Radio Shack or similar retail stores. By the way, in case you didn't know, a quarter-wave "stub" rejection filter has *no connection* to the "open end" of the coax. Don't short-circuit the open end, and don't terminate it with anything, or it will be completely ineffective. The quarter-wave "stub" works on the principle that the impedance of a transmission line is inversely proportional to its termination impedance every quarter-wave. If you leave a quarter-wave stub open-circuited at one end, the reflected impedance will be a short circuit at the opposite end, on the frequency where the stub represents a quarter-wavelength in coaxial cable. Thus, a quarter-wave "open-circuited" stub will look like a short circuit on its resonant frequency, and will shunt interference to ground. It works.

If you try hard enough, TVI is possible to eliminate. I've never seen a situation yet where I couldn't do it. It may take several hours, it may take a few dollars, but it can always be done.

Telephone Interference

This is a broad category that applies to all appliances connected to a telephone line: telephone instruments, computer modems, fax machines, etc.

Telephone interference is rare at VHF-UHF levels, but can be very troublesome at HF. One reason is that VHF-UHF signals are quite well shunted to common by the capacitance of the lines and instruments connected to them, but at HF this isn't the case. Another reason is that wavelengths are so much longer at HF that the near field interfering signals might be as far as a few hundred feet away on HF, while the near field is very short on VHF-UHF. Radiated signals are reduced in intensity by an inverse square law based on the wavelength being used. While 100 feet is very "close" on 80 meters, it is very "far away" on 2 meters.

Many telephone interference problems can be eliminated by terminating unused jacks. Since telephone lines are often "daisy-chained" (connected from jack to jack to jack within the house), any unused jack wiring becomes an antenna which can be an efficient receptor of signals. If you have telephone jacks in your home (or a neighbor's home) which are unterminated (no telephone instrument connected), these can cause problems. The easiest solution is to terminate them, whether a telephone instrument is used there or not, with correct passive terminations. Such terminations provide a 500-ohm terminating impedance (*not* a resistance alone!) across the line, simulating a real telephone-type instrument, and they are available for a couple of dollars from your local phone company or at Radio Shack.

If you've tried this and still have interference problems, try another trick: Go to the point of entry of the telephone line to the house and find the connection box located there. This is often a four-terminal "block" with brass machine screws, flat washers and nuts, where the telephone line from the utility connects to the house telephone wiring. Frequently, you will find unused wires just "floating" (not connected to anything) there. Any and all wires floating at this point (wires just twisted together and not connected to anything) can be grounded, since they're not being used, anyway. Strip the insulation off the unused wires, twist the exposed copper conductors together, and tie them to the nearest ground post, which is likely to be close by, since the telephone utilities usually provide an earth ground inside of or nearby this junction box. By grounding unused conductors in telephone wiring, you can short out some RF current which might be causing interference directly to ground. Also, since telephone wiring is often "twisted" along its route, grounding unused conductors tends to "shield" the entire bundle of wires, which can also help reduce RF interference.

If you try both of the measures outlined above and still have interference

problems, try using single-instrument telephone filters. These are sold by many manufacturers as "aftermarket" fixes, and usually have modular telephone plugs and jacks included. If telephone filters are used, they often work best when installed right at the telephone instrument (or computer modem, or FAX modem, or whatever), as close as possible to the equipment. Don't bother installing a telephone filter at the wall receptacle when a cord will be used between the wall socket and the instrument. It will be much more effective when used right at the telephone (or whatever). Sometimes a filter might be necessary in the handset cord as well. I've even seen situations where one filter did very little to reduce interference, but two or three filters in series at the same point worked perfectly. These filters usually retail for about $10 each and, if they work, are well worth the investment.

If you try all the tricks above and still have telephone interference, take a look at how your antenna transmission line is routed. Is it close to, or in parallel with, your (or your neighbor's) household telephone wiring? If so, move it! Is your HF antenna close to the telephone wiring from a street utility pole to your home? If so, move it! You are free to reroute telephone wiring as required to cure interference problems. You don't need the telephone company's permission. Just be sure that if you do reroute telephone wiring outdoors, use the telephone company's original cable, which is designed to withstand the abuses of mechanical stress and weather. Inside your home, these factors are unimportant and you can pretty much do whatever you want, since you own this wiring, anyway.

If in the process of investigating telephone interference you happen to find frayed, worn, or broken cables outdoors (between the telephone company's street wiring and your home), call the phone company and ask them to replace it. Beware of telephone lines. As benign as they look, they do carry a "ring" voltage capable of inducing quite a shock, and they need to be well insulated. Don't handle exposed conductors with bare hands. (This hazard only exists during a "ring," but you never know when that might occur.)

You might also try different telephone instruments. The complicated ones with electronic memory for telephone number storage and redial are sometimes more prone to interference than the old-fashioned "no frills" phones, purely because they contain additional electronic circuitry. The old Western Electric-built telephone instruments (remember the 1960s and 1970s?) which had a simple one-transistor tone oscillator, carbon microphone element and mechanical bell ringer were pretty "bulletproof" compared to most of the cheapie imports we use today. You can still find these simple but effective telephones, both new and used.

If worse comes to worst and you can't fix a telephone interference problem, try calling the phone company. Although their line filters are rarely effective, they do occasionally help, and they might find some unique problem in your local wiring or instruments. (But don't count on it: Since the divestiture of AT&T several years ago, I've found the local operating companies critically lacking in technical talent.)

"Grounding station equipment can also help prevent lightning damage in the event of a direct or secondary strike, but is by no means a "fail-safe" precaution."

If worse comes to really worst (like civil actions, threats with deadly weapons, etc.—don't underestimate the actions of a neighbor who can't use his telephone!), experiment with band and power changes. If you clobber your neighbor's phone when using 100W on 20 meters, try 10, 12, 15, 17, 30, 40, 80 meters instead. Or you might try reducing power to the minimum required to make contacts (which is a procedure we're all supposed to follow according to FCC Part 97, anyway). Although I'm an advocate of "Why use low power when a kilowatt will do the job?" thinking myself, experimenting with operating frequency and power level might reveal some useful data. You might find that the interference is frequency-specific, for which the obvious conclusion might be that the telephone wiring in question is resonant on some band you choose to operate. This is good to know, because telephone wiring can be altered in length without any notable change in performance, and simply adding or subtracting some length to your neighbor's telephone instrument wiring might shift the resonance out of the band you're trying to use.

Alternatives

Filters on your transmitters will be of absolutely zero help with telephone interference; however, a good low-pass filter on your HF transmitter *might* help reduce TVI ("might" is the key word here—don't count on it). If you're using modern-day equipment, with a high-quality coaxial transmission line connected to resonant antennas that are well matched, a low-pass filter may not help at all, but that doesn't mean you shouldn't try one. If you do try a low-pass filter on your HF transmitter, get one that is well-shielded and rated for considerably greater power output than you ever intend to use. Transmitting filters used on VHF-UHF transmitters almost never help reduce interference to appliances not intended to receive amateur radio signals.

If you're using an "end-fed wire" HF antenna, this is often asking for trouble. Although end-fed wires work just fine on any frequency where the wire length is not a half-wavelength, it usually means strong RF fields inside your own home, which can coincide with angry family members. There are some compelling reasons to use end-fed wire antennas (like no transmission line loss, regardless of VSWR), but if you have TVI/RFI/telephone interference, they are best avoided.

Experiment with grounding. Sometimes a good, low-impedance ground on your transmitter, or the interfered-with appliance, or both, can help. However, I've seen as many cases where a good ground makes no difference at all, and some cases where the grounding actually made interference worse. "Grounding" is not a magic cure. If you decide to try grounding, there are a few points to ponder:

1. The primary reason for a station ground is not to reduce interference. It is a safety precaution that can help save your life should other grounding systems (such as through your three-wire AC line cord) fail. Grounding station equipment can also help prevent lightning damage in the event of a direct or secondary strike, but is by no means a "fail-safe" precaution. At least one ham I know lost his home to a direct lightning

strike, even though his station was as well grounded as any I've seen.

2. There are differences between types of "grounds." A *DC* ground is any ground path that eventually leads to earth, no matter how long or resistive it may be. An *RF* ground is one offering low *impedance* (not necessarily resistance) to earth on a specific frequency or range of frequencies. It is almost impossible to achieve an RF ground at VHF-UHF since the path to earth would have to be just a few inches long at most. At HF, a true RF ground is achievable, but not easily. One example of a reasonably effective RF ground is the one that I use: a pair of 8'-long copper-clad steel ground rods driven into the earth directly below my operating bench (which is in the garage), connected to the station equipment using 2"-wide tinned copper braid capable of conducting more than 1,000 amperes of current. Such braid costs about $5 per foot retail, and isn't easily found. Also, not many folks can install ground rods directly below, and less than five feet from their station equipment. I did it by using costly masonry drill bits (1"-diameter) to drill through about one foot of solid concrete in my garage floor, then using a 16-pound sledge hammer to pound the ground rods in. This task took several hours to accomplish, since drilling through 12" of concrete isn't easy, and the ground was fairly hard. It also used up two masonry bits costing more than $30 each. And the work would have been impossible to do if the station had already been installed. (I did it prior to building the operating bench or installing any equipment.) Was it worth the expense and effort? Probably not. Do I really have an effective RF ground? Maybe. I wouldn't bet the farm on it.

If you have a second-story (or higher) ham shack, the likelihood of getting a real RF ground to your station is minimal. You're too far away from earth. However, this does not mean you cannot achieve a *tuned*, or frequency-specific, RF ground for a particular frequency of operation. One reasonably effective "counterpoise" (artificial ground, which works for RF but is neither a DC ground nor a hazard-preventing ground) is to use a quarter-wavelength "radial" of wire connected to the ground post of your equipment, with the free end connected to nothing at all! Trust me, it works. The MFJ product which effects an artificial ground and is tunable might also work in some cases.

Cable TV converter boxes also vary in workmanship and engineering quite a bit. Some are in plastic cases which are completely unshielded. Some are in metal enclosures which appear to be an effective shield, but really aren't. Most have only two-wire AC line cords which provide no grounding at all. In some cases I've seen, simply shielding the converter box using household aluminum foil has helped reduce TVI. These "boxes" are really cheaply made and designed to a price, rather than performance, specification. They should cost hundreds of dollars to perform their intended tasks, but in reality they sell for very little and barely work. Most have the insignia of an American company on them, but they're actually built offshore, in Taiwan or somewhere with even lower labor costs. There's nothing wrong with offshore manufacturing, except that these factories often cut corners on what were already cheap designs. If it has an AC power cord on it, the equipment is undoubtedly "UL Listed," which means absolutely nothing with regard to performance.

"Many consumer devices such as personal computers and modems are "FCC Class B" accepted, which similarly means nothing at all."

Check your antenna system, too. If it's an old installation, your connections could be oxidized or corroded, which can help generate higher levels of interference than a system built with shiny new components. Also check your coaxial cable. Brand-new, high-quality coax made by reputable manufacturers is usually pretty good; but lower-cost cables, surplus cables, or ones that have been in use for a few years or more may not be. Coaxial cables, especially when used outdoors, do deteriorate and require replacement.

While SWR is not a figure of merit for antenna performance, it can be an indicator of something being right or wrong. If you are using an antenna with a high SWR and "tuning" it in the shack to make it match better, there is still a mismatch between your feedline and your antenna, and there are still standing waves on your transmission line. Antenna mismatch will often cause transmission line radiation, which may tend to make interference problems worse. Adjust your antennas so they match your transmission line. This is not only more effective than using antenna tuners, transmatches, etc., it can also help reduce radiated interference.

You might also consider raising the elevation of your antenna, to get it farther away from the appliances you're interfering with. I had an interesting experience with TVI on 6 meters (50 MHz). This band is notorious for causing problems with TV Channel 2 reception, since 50 MHz is very close in frequency to TV Channel 2 to begin with. I was running 100W output power to a six-element beam up about 35 feet, and causing TVI to two or three neighbors. I tried several cures, none of which worked. In desperation, I finally tried raising my 6 meter antenna. I raised it to 45 feet, then to 55 feet, and finally to 60 feet, while testing for TVI. All these changes took some time, as I was adding tower sections!

Two weeks or so later, after adding the last tower section that raised the beam to 60 feet, I ran some TVI tests with the neighbors again. The interference had literally vanished! I raised my transmitter power. Eventually, I had 1200W output power on 6 meters (from a pair of 3-500Z's) and literally zero TVI. Previously, I had severe TVI with the same transmitting equipment (and much lower power) and the same beam antenna, but the beam was up only 35 feet. The difference was that when the beam was up 35 feet, it was only slightly above my neighbors' rooftops, and nearly in line with their TV antennas. By raising the antenna another 25 feet I was well above their homes and their antennas, thus considerably reducing the strength of my radiated signal to their TV antennas, even when operating at far greater output power.

Agency Approvals

They mean absolutely nothing. Really. Many consumer electronic and electrical appliances are "UL Listed," "UL recognized," "FCC Class B approved," and so forth. It doesn't mean a thing. U.L.

(Underwriters Laboratories) and C.S.A. (Canadian Standards Association), as well as many foreign agency approvals (T.U.V., V.D.E., etc., ad nauseam) don't mean anything in the real world. Many consumer devices such as personal computers and modems are "FCC Class B" accepted, which similarly means nothing at all. While PCs and peripherals are all "Class B approved," they radiate RF energy like mad, and can similarly receive RF energy that can render them useless in strong RF fields.

U.L. and other agency approvals have nothing to do with performance. U.L. employs almost no real engineers, and has literally zero experience in RF interference or other real-world situations. They "list" or "recognize" equipment based on safety criteria (meaning, the equipment probably won't catch fire when operated according to instructions), irrespective of any performance ratings or criteria. I've dealt with them quite a bit over the past 25 years or so and am extremely unimpressed with their knowledge of electronic circuits. To wit, I asked four different U.L. "engineers" how they determine if electronic equipment is safe for use. Without referring to manuals, not a single one could answer my question. After referring to manuals, none gave a satisfactory answer that even peripherally indicated they had any experience with electronic circuits. If these folks are the "experts," we're in serious trouble.

> ***"This can open a Pandora's Box of problems that will haunt you forever."***

When All Else Fails

Ask your neighbors to contact the FCC. Don't be afraid! The FCC isn't out to "get" you. If you're a licensed amateur radio operator and are using your equipment within its ratings and limits (and the limits of your license class), you're probably in good shape. The FCC recognizes that amateurs are licensed to transmit, and your neighbors are not licensed to receive. Reception of television and radio signals is a privilege, not a guarantee. Even telephone calls unencumbered by interference are not guaranteed by the FCC. Indeed, your local telephone utility company guarantees its users some degree of communications which should not be encumbered by radio interference, and if its users find telephone services to be worthless, they really don't have to pay their telephone bills until the problem is corrected.

Utilities are regulated by the Public Utilities Commission, which guarantees users some degree of service in return for fees paid. Communications services are further regulated by the Federal Communications Commission, which recognizes the weaknesses of many user appliances and are usually empathetic with amateur radio operators. It is a ham's responsibility to try his (or her) best to resolve interference problems prior to requesting FCC intervention. But when all else fails, you'll be surprised to find that the FCC is not an enemy, but rather an advocate. I've dealt with the FCC on interference problems more than once, and they've never asked me to stop transmitting yet.

Summary

Interference problems can all be resolved. It takes mutual cooperation on the part of the amateur and the complainant. If the complainant won't let you help him or her, you won't get very far in negotiating with them.

Don't try to "fix" your neighbor's television, radio, telephone, computer or whatever. This can open a Pandora's Box of problems that will haunt you forever. I once voluntarily installed a high-pass filter inside a neighbor's TV set (more than 20 years ago), which did help resolve an interference issue. Two years later, that neighbor tried to sue me for ruining her television, when her picture tube failed and required replacement. (Trust me, I never touched her picture tube.) It's better to recommend filters and so forth, and recommend they be professionally installed or installed by the user. It's even a nice gesture to offer to pay for such filters. I've done it, and I'd do it again, if it makes my neighbors happy.

For a short while I lived in a townhouse community where I had neighbors quite close by. I didn't get into their televisions, but I did cause quite a problem with their telephones. As a neighborly gesture, I offered to buy them all telephone filters. The filters worked great, but it cost me more than $200 to buy all the filters required. This sounds like a lot of money, but I don't regret the decision. It quelled a real problem and allowed me to operate the HF bands without having neighbors complain about it! (One case of telephone interference was so severe, no amount of filtering seemed to help. I offered that neighbor free use of my portable cellular telephone, which had no interference at all, when he needed to call someone and I was on the air. The bills amounted to maybe $10 or $15 a month, but the neighbor was satisfied, I was working DX, and the world was a nice place.)

If you still have problems, write or call me and I'll try to help you out. If you don't, then this article served its purpose. 73 and good DX!

HAM TO HAM

Your Input Welcome Here

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

Since we began this column three issues ago, a number of worthwhile ideas have been received and they continue to arrive daily. Many thanks to all who've contributed their time and effort to make this a success, and I'm hopeful that the response seen so far will grow even more enthusiastic in the future...remember, this should be your column, with your ideas and suggestions.

Here's a basic rundown of what I'm looking for in the way of reader input. Everyone has different experiences in amateur radio, with different equipment and varying setups; each of us has encountered any number of instances where we've made improvements, both major and minor, to what the equipment manufacturers "think" that we want. Some of the modifications are primarily operational in their nature, others make the equipment more technically sound. I'd like to hear about your innovations, with the possibility of passing them on to all of the others reading this column. That's what "Ham To Ham" means, one ham's helpful hits, ideas or suggestions to another who might be in a similar situation or have similar needs. Hams have always enjoyed helping one another, that's part of the fun of the hobby, and this column is a way of extending that helpfulness to many, many others all at once.

Not everyone wants to write a complete, long, drawn-out article on an innovative idea that they may have come up with, so here's your chance to jot down the basic details, in casual form, and I'll put the finishing touches on it, if need be, for the column. Don't worry about your writing style, just try to be as complete as you possibly can, but even if you're not sure, send it to me and I'll let you know if I feel that more information is needed. I'm primarily interested in down-to-earth, practical ideas that others can duplicate with relative ease. Here's an example of a simple idea, something that's easily duplicable by most hams, yet many may have been reluctant to apply it to their own situation.

Pilot Lamps and Today's Radios

Have you noticed how difficult it's become to change a burned-out pilot lamp in most of today's modern transceivers? In the "good old days"—when radios and pilot lamps were both a lot bigger—changing a dead lamp was a pretty straightforward, easily accomplished job. Lamps were usually mounted in sockets, and normally just a twist of the wrist popped the lamp right out, ready to install a new one. Not so anymore! Most lamps are now on tiny wires, soldered in place and often buried deep within the radio's front panel wiring. It's become such a problem that many hams don't bother changing the lamps when they do burn out, or they wait until something else much bigger in the set needs attention, changing the pilot lamp then as something of an aside to the larger problem.

What follows may not make the task of lamp replacement any easier, but it might just double or triple the time between pilot lamp failures, and it's not usually too difficult to accomplish.

Here's the first tip: When a pilot lamp does burn out, most hams probably think in terms of going to the radio's manufacturer for a "direct replacement," but often that's the most expensive and time-consuming route to take. Here's an alternate approach that's ordinarily much, much easier. Radio Shack stores stock a number of small, low-voltage lamps, most of which work on what your transceiver supplies as pilot lamp voltage—usually 12 volts DC. By the way, using a replacement lamp rated at a higher voltage is fine, just as long as it will provide enough brightness once it's in place. In fact, a higher voltage lamp will last quite a bit longer than one that's rated right at the nominal supply voltage. That leads us into the rest of the story. How do you extend the life of those tough-to-get-at little pilot lamps?

If you lower the supply voltage to any incandescent lamp, you'll increase the lamp's life dramatically. Tests have shown that the life expectancy of an incandescent lamp zooms upward as the voltage across it goes down, and of course, vice versa. Lowering the voltage across a 12-volt lamp by just a couple of volts, for instance, will extend the lamp's expected life by two or three times! Just a series resistor in the lamp's supply lead will do it for you, but there are some other considerations. You'll have to determine how much light loss is acceptable in your particular operating configuration, because there will be loss of brightness if the voltage to the lamp is reduced. Once you have determined how much illumination you can afford to lose, you'll need to know the value of the resistor needed to drop the voltage just enough to accomplish that objective. Finally, the power to be dissipated by the resistor will determine what wattage resistor is needed.

Lowering the voltage across an incandescent lamp will definitely reduce its light output and it will also shift its color somewhat toward the red region. The more the voltage is lowered, the more red-shift occurs.

I have a couple of flood lamps illuminating the front of my house each night that are wired in series, i.e., the lamps run at 1/2 voltage across each lamp. They're very much on the "warm side"—red-shifted—but have been going for years and years each night without burning out, because voltage-rating-wise, they're loafing along!

Getting back to our pilot lamp discussion, you can easily determine what resistor to use in series with each lamp by using Ohm's Law: Voltage drop desired (V) divided by the lamp's rated current (I) equals the correct resistor (R) needed and Voltage drop (V) desired times the lamp's rated current (I) equals the resistor's wattage (P).

By way of example, let's take the Radio Shack #272-1141 lamps mentioned earlier, which have a current rating of 25 milliamps—or 0.025 amp—and assume that we would like to drop the 12-volt lamp supply by 2.5 volts—down to 9.5 volts. Plugging in these values we get: 2.5 volts ÷ 0.025 amp = 100 ohms and 2.5 volts times 0.025 amp equals 0.06 watt.

Now we know that we'll need a 100-ohm resistor in series with each lamp, and that a 1/2-watt dissipation rating on each resistor will give us a good margin of safety.

Another way to lower the voltage to all of the lamps in the set at one time would be to use a 3-terminal adjustable voltage regulator supplying something less than 12 volts to the lamp supply bus, but in most cases, that's something of an overkill. You would also have to be sure that nothing else is tapped off of the lamp supply bus that might be adversely effected by a slight voltage reduction. The individual resistor in series with each lamp is usually the safest approach unless you know the transceiver's circuitry well.

Remember, the more you can lower a lamp's voltage from its nominal rating, and still have enough light output from it, the longer that new pilot lamp will last once it's in service.

Reducing Scratches

Sometimes accidents happen, and a plastic meter face, dial cover or even a wristwatch faceplate can become marred with an ugly scratch or dig, often making it difficult to even read through the scratch mark.

Next time that happens to you, try using a small amount of metal polish, such as Brasso™, to polish out the imperfection...it really works. Most of these products are composed of a very fine abrasive that, if used properly, will eliminate or minimize many scratches—even relatively deep ones—restoring the damaged piece to usable condition again.

Try folding a paper napkin, and with the tip of your finger

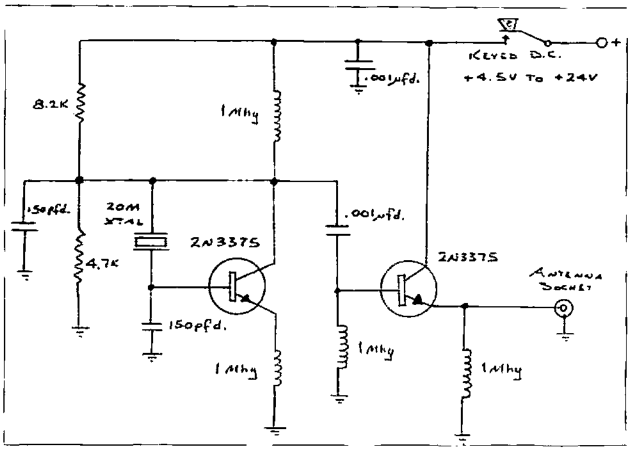

Fig. 1. 4X1UF's ultra-compact 20 meter CW QRP transmitter schematic diagram. See text for further details.

backing it up, apply a small amount of polish to the damaged surface. Take your time, applying only the amount of pressure needed to remove enough of the surface plastic to polish out the scratches in question. You might want to try this on a couple of scrap plastic pieces first, just to get a "feel" for the procedure. Rub over the scratch several times and then wipe the dried polish completely off. If the surface has "fogged" a bit, repeat the procedure, but this time using progressively lighter pressure.

For very light scratches, even ordinary typing paper may be just abrasive enough to polish the surface sufficiently. Try using the paper just as is—without any additional external abrasive applied to it.

Most reasonably sized marks—and even some pretty big ones—can be removed or greatly reduced in this manner. It even works on scratched CD-ROM disks, but again, better to practice on a "throw-away" one first.

Submitted by: Herb Foster AD4UA, 3020 Pennsylvania Street, Melbourne, FL 32904-9063

Moderator's Note: most cleansers and polishes will exhibit the abrasive effect that Herb refers to above, so you might want to try a number of them—keeping notes on which work best for you—on several samples of scrap plastic. You might also want to try a mild-abrasive automobile rubbing compound or an optical lens grinding compound as well. Jeweler's rouge, a very fine abrasive in an oil-based cake form, is also very useful in the same manner—you might check with a jeweler's supply house or your own neighborhood jeweler to see about obtaining a small container for the next time you need it. Jeweler's rouge is also excellent for cleaning tarnished connector contacts and intermittent battery connector springs, as well as your XYL's gold rings and bracelets! Brasso, mentioned above, is a registered trademark of Reckitt & Coleman of Wayne, NJ.

Two-Stage QRP Transmitter

All the way from Israel, Lavee 4X1UF contributed this interesting little two-stage, 5-watt, 20-meter CW QRP transmitter circuit for experimental purposes.

In the circuit diagram of the Fig. 2, the first 2N3375 transistor is wired as a Pierce Oscillator, and is capacitively coupled to a second 2N3375 that functions as a buffer as well as an impedance converter. Lavee writes, "...by drawing as much current as needed by the stage," the second 2N3375 "...acts as an automatic antenna tuner. The lower the impedance, the higher the current" drawn from this stage. The need for an external antenna tuner is therefore minimized, except perhaps as a tuned circuit for harmonic reduction, since no tuned circuits are employed within the two-stage transmitter itself. These days, some sort of harmonic reduction would be well advised.

"The need for an external antenna tuner is minimized, except perhaps as a tuned circuit for harmonic reduction."

Lavee built his unit into a very small copper box, bolting the 2N3375s directly to the box and bringing the RF out via an RCA-type "phono" jack. Direct point-to-point wiring is used, with all grounds soldered right to the copper box itself with the shortest possible leads. With 24 volts keyed DC applied, he was able to realize about 5 watts of RF output on 20 meters. He further cautions that the box can get very warm after a time, so either additional heat-sinking might be required, or key-down time kept to an absolute minimum—lower V_{cc} input voltage would also reduce heat, along with the output power. A small 12-VDC fan might be a worthwhile addition if the heat dissipation is still too great. Lavee commented that after final testing, he covered all of the internal components with a heat-dissipating epoxy for additional component mechanical stability as well as better heat transfer.

From 4X-land, this is an interesting circuit with lots of potential for QRP enthusiasts. Questions and comments should be directed to: Lavee Israel 4X1UF, c/o International Electronics Services, 12/21 Got Levin St., Haifa 32922, Israel.

That's our "Ham To Ham" column for this month. Please keep your ideas, tips, suggestions and shortcuts coming and we'll use as many of them as possible in each of the coming months. Please send them to the address at the top of this column, not to *73 Magazine* directly.

Note: The ideas and suggestions contributed to this column by its readers have not necessarily been tested by the column's moderator nor by the staff of *73 Magazine*, and thus no guarantee of operational success is implied. HOMING IN

Radio Direction Finding

Joe Moell P.E. KØOV
PO Box 2508
Fullerton CA 92633

More About Hamcon/ Foxhunt-95

"We need more young people in ham radio!" Wayne says it. I've said it, and you have probably said it, too. What if I told you that there is a way for kids of almost any age to learn about radio without realizing they are being educated, while they have so much fun they won't want to stop? They'll also be getting lots of fresh air and exercise, far more than they would get sitting in front of a computer screen. Best of all, the kids don't need to be licensed; they can start immediately.

Yes, such an activity exists. In some eastern European and Asian countries, it is so popular that it's part of Physical Education in schools. The sad fact is that it's rarely done stateside. Hams in our education industry haven't discovered it yet. This best-kept secret is a sport called "foxhunting."

Hide-and-Seek With Radios

Unlike more familiar mobile "T-hunts," an international-rules foxhunt is an on-foot search for several concealed mini-transmitters in a large outdoor setting. Kids love it, and so do adults. I explained the concept in detail in last month's "Homing In." I also began the story of Hamcon/Foxhunt-95, Southern California's first international-style radio direction finding (RDF) championship. It was held September 3 on the Fort MacArthur Military Museum grounds in the San Pedro area of Los Angeles. I served on the committee of Southern California Six Meter Club members who put on this 2 meter event for the 1995 ARRL Southwestern Division convention.

Photo A. Fox #3 was next to the long staircase on the edge of Batteries John Barlow and Saxton, an abandoned WWI shore defense site at Fort MacArthur. One hunter hasn't realized yet that he is standing on top of it.

Hamcon/Foxhunt-95 simulated as closely as practical a European/Asian foxhunt. Our rules were based on International Amateur Radio Union (IARU) rules for direction-finding championships. Unlike IARU events, there was no separate division for women and competitors in all divisions were required to search for all foxes. Age divisions were different from IARU classifications.

International-style foxhunting is new to Southern California, but that doesn't mean all Hamcon/Foxhunt-95 participants were complete greenhorns. Many of the forty who signed up were experienced mobile T-hunters who had learned techniques for "sniffing" out transmitters on foot, whereas others had never tried RDF before. How could we put on a hunt that challenged the experienced T-hunters but gave first-timers a chance to do well?

The fox-hiding subcommittee decided to put out six foxes. Two transmitters would be easy to find, two would be really tough, and two would be in-between. Foxes #6 and #2 were intended to be the easy ones. We hid #6 under the concrete cover of an abandoned 40-year-old underground command post for Nike defense missiles on a hilltop 900 feet southeast of the start point. The antenna for Fox #2 was N6MI's horizontal dipole in a tree 400 feet west of the finish line. Both of these foxes were high and in the clear, relatively speaking, so hunters should have gotten sharp bearings.

IARU rules require red and white flags (called prisms) next to each fox. They are appropriate in the deep-cover forests where world championships are held, but they would have been far too conspicuous in the fort areas. So we did not use them. The bright orange punches within five feet of each transmitter were easy to spot and provided sufficient visual identification.

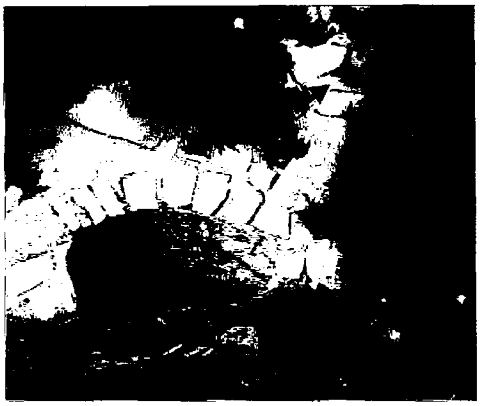

Photo B. The most dastardly fox hiding spot was deep inside this drainage channel, 200 feet from the beach. The orange card-marking punch is just barely visible in the wall-climbing plants.

Fox #3 was supposed to be very hard. It was on the steep slope of a 50-foot-deep football-field-sized pit that used to be part of a World War I mortar emplacement (Photo A). Its antenna was a twin-lead J, most of which was buried a couple of inches into the dirt next to the long stairs. The idea was to "light up" the entire pit with lots of RF and create many signal reflections. The ultimate challenge was Fox #4, which was underground, five feet into a sea-level drainage channel near the southern end of the park (Photo B). All foxes except #4 were at least 50 feet from the nearest trail.

The shortest possible route reached the foxes in the following order: #3, #5, #6, #1, #4, #2. Hunters traveling that route directly would have gone 1.35 miles. This is about one half of the shortest route in a typical IARU championship foxhunt. Of course, nobody's route was close to being that short. Overall winner Scot Barth KA6UDZ found all foxes in 66 minutes and Senior Division (over age 46) winner Marvin Johnston KE6HTS did it in 76 minutes (Photo C). By comparison, a Hungarian and a Russian completed a much longer five-fox 2 meter course in just 47 minutes at the 1994 World Championships in Sweden.

According to the fox-hiding corollary to Murphy's Law, "Everyone will easily find the foxes that you think will be hard, and vice versa." The pit didn't create a pool-table effect for Fox #3 signals. Eighteen hunters found it. On the other hand, the high horizontal dipole of Fox #2 must have caused some unusual signal reflections, because many hunters reported that bearings to it crossed on top of a hill 400 feet northeast of it. The fox found by the most hunters (28) was #5; the one found by the fewest hunters (8) was #1. Both had been expected to be medium difficulty foxes.

This foxhunt was the last event of the convention, on Sunday afternoon. All day Saturday, a half dozen or so "micro-Ts" transmitted for a few seconds each from hiding spots around the Queen Mary convention site, including the hotel, exhibit area, and parking lot. This gave everyone a chance to check out RDF gear and practice techniques.

A few eager entrants didn't wait until Saturday to get ready. Rick Barrett KE6DKF, who

Photo C. Marvin Johnson KE6HTS picked this high spot overlooking the ocean to take a bearing. He took first place in the Senior Division.

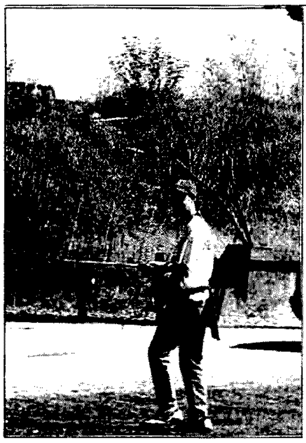

Photo D. Tom Mirabella KD6AAN, age 14, took first place in the Youth Division. He found more foxes than his dad, Ken KM6YH.

placed third in the Prime Division (ages 18 through 30), was glad he had practiced diligently. "Scott Barth KA6UDZ, another hunter, and I went up to Glendora to a local sports park several times," he told me. "We would each hide a fox in the park and then we'd hunt each other's foxes down. Once we found all of them, we'd move them and find them again. We did it after dark so we would not see each other hide them. This allowed us to get used to our equipment, so we could trust it and not just what we saw."

Everyone Is Able

Fox hunters who win international championships are true athletes who train just like world-class competitors in any other running sport. By contrast, Hamcon/Foxhunt-95 entrants were a cross section of ordinary hams, ranging in age from 11 to 70 (Photo D). The median age was 38. There were no cross-country runners, and two could not run at all. The story of these two is proof that foxhunting is a sport for almost everyone.

Photo E. Mike Obermeier KD6SNE "sniffs" in his wheelchair and T-hunts regularly on 2 meters in a converted mail delivery truck with a 4-element quad and a Roanoke Doppler. The photo isn't backwards; the steering wheel really is on the right side.

Mike Obermeier KD6SNE is a regular at Southern California mobile T-hunts. Because of a spinal cord injury, Mike has adapted his T-hunt vehicle to include hand controls for the accelerator and brakes (Photo E). In just a few seconds, he can maneuver himself out of the truck and into his sports wheelchair for sniffing out the T.

When I promoted this foxhunt at a mobile T-hunt in August, Mike told me he really wanted to compete. He kept asking, "Can I do it in my chair?" I knew the site had plenty of paved and unpaved trails, but there would be no way to place all the foxes so he could roll right to them. There are no provisions in the IARU foxhunt rules for this sort of situation. Mike didn't want a special course just for him, nor did he want the course made easier on his account. All he needed was a way to finish closing in after he had done the basic RDF work on wheels.

Fortunately, I had an expert nearby for consultation. My wife April WA6OPS is a Registered Occupational Therapist and former rehabilitation department head at a major medical center in Orange County. Occupational Therapists are trained to find creative ways for persons with disabilities to adapt to their physical limitations and

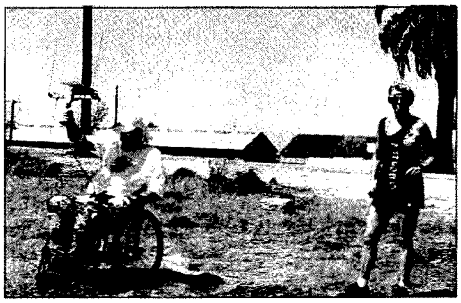

Photo F. KD6SNE cruised the foxhunt course in his wheelchair. Christie Holoubek KØIU, his Extender, went into the brush on his command to uncover foxes and punch his competitor card.

***Photo G.** On the downhill, KØIU had to move fast to keep up with KD6SNE.*

return to regular activities of their daily living.

April suggested that Mike be provided with an assistant on the foxhunt course to perform search duties in areas of the park that were inaccessible to his wheelchair. I countered that the competition was for individuals only, not two-person teams, and that other contestants might consider it unfair to go up against the team of Mike and an assistant. After some discussion, we agreed that the assistant would be selected by the hunt committee and would be allowed to act only as an extension of Mike's range. Mike would do all the RDF work and maneuver his chair as close as possible to the foxes. Then Mike's Extender would go into any inaccessible places and search, without equipment, at his direction (Photo F).

Mike thought this idea was great and quickly agreed to the terms and conditions. Christie Holoubek KØIU agreed to act as his Extender. There was no concern about Christie being able to keep up with Mike, because she is an accomplished marathon runner (Photo G).

One week before Hamcon/Foxhunt-95, I received e-mail from Marvin Johnston KE6HTS of Santa Barbara. He and Dennis Schwendtner WB6OBB were coming to the hunt and he wanted to know if Dennis could participate on a team. I already knew that WB6OBB's keen hearing had made him a successful "navigator" on mobile T-hunts in Santa Barbara for many years, despite the fact that he is sightless. I told Marvin that there would not be a team competition, but we would try to find another good Extender so that Dennis could hunt.

WB6OBB liked the idea, so April asked an acquaintance who had expressed interest in amateur radio to be his Extender. April's instructions were that she could act only as eyes for Dennis, and could not do any RDF for him. Besides insuring his safety, she was allowed to describe to Dennis the terrain features and the presence of other hunters in the area in which they were searching (Photo H).

No one at the foxhunt starting line was more excited than Mike and Dennis. Of course, not all sporting events turn out like a Rocky or Mighty Ducks movie. Neither Mike nor Dennis won a medal. However, both received certificates for successfully finding foxes, and their extenders got a real workout. I'm sure all four are hoping that organizers here and abroad will improve the rules so all future international-rules foxhunts are as accessible to handicapped hams as this one was.

As you can see from the photos, Hamcon hunters used a wide variety of RDF gear, from the commercial sets used by KE6HTS and KD6SNE to KD6AAN's yagi and the foil-tube attenuator of WB6OBB. Every hunter has personal preferences for equipment. Selecting just the right sniffing setup for your needs will be the topic of an upcoming "Homing In" column. Meanwhile, keep me informed about both mobile T-hunting and on-foot foxhunting in your area. Write to the address at the beginning of this article or send e-mail to me via Internet (Homingin@aol.com) or CompuServe (75236,2165). 73

***Photo H.** Long-time T-hunter Dennis Schwendtner WB6OBB didn't let his blindness keep him from having fun at Hamcon/Foxhunt-95. Future ham Linda Reagan served as his Extender.*

HAMSATS

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB

Houston, TX 77083

The AMSAT Annual Meeting

The 1995 AMSAT Annual Meeting and Space Symposium was held October 6-8 in Orlando, Florida. Over 200 satellite enthusiasts listened to dozens of presentations and visited the Phase 3D integration facility. For all participants it was a fantastic weekend. STS-73 was scheduled for launch during the weekend only 40 miles away at the Cape, but due to weather and other delays, it was a hamsat weekend and not a hamsat/shuttle weekend.

Photo A. Phase 3D Satellite Project Leader, Dr. Karl Meinzer DJ4ZC, addresses the 1995 AMSAT Space Symposium in Orlando, Florida.

Friday

This year the presentations began Friday before noon with a paper by Bob Bruninga WB4APR about a new software program called APRtrack. Gwyn Reedy W1BEL of PacComm described the capabilities of the program and its use for determining the locations of ground stations and spacecraft using packet radio and GPS (Global Positioning System) data. Shareware versions can be found on various BBSs, while registered copies can be purchased from WB4APR or AMSAT. AMSAT VP for Manned Space Activities Frank Bauer KA3HDO, John Nickel WD5EEV, and Matt Bordelon KC5BTL updated the group on the progress of SAREX, the Shuttle Amateur Radio EXperiment. SAREX did very well in 1995 with random QSOs and many fine scheduled contacts with schools from the ham-astronauts.

Ignacio Martinez CE2MH of AMSAT-CE (Chile) described the Fodtrak tracking and tuning software. The program was developed in Chile to help fund the satellite CESAR-1.

Other afternoon talks included methods of developing and utilizing satellite gateway nodes by Barry Baines WD4ASW, development of microsat ground station software for Linux and X-Windows by John Melton GØORX/N6LYT, ways to extend the lifetime of scientific satellites by Philip Chien KC4YER, and details on the success of the joint AMSAT/TAPR (Tucson Amateur Packet Radio) DSP-93 project. The Texas DSP-93 crew included TAPR President Greg Jones WD5IVD, Bob Diersing N5AHD, Bob Stricklin N5BRG, and Frank Perkins WB5IPM.

Finishing the afternoon activities was Phil Karn KA9Q with a demonstration of digital voice via the World Wide Web on the Internet.

A brief dinner break followed. Evening presentations began with a slide show on satellite DX by Mikio Mouri JA3GEP.

Doug Howard KG5OA followed with the latest exploits of balloon enthusiasts in Texas. He described the many payloads in previous and current packages that the groups send to the edge of space.

David Liberman XE1TU showed a video of the attempted launch of UNAMSAT-1 on a converted Russian ICBM. The launch failed, but UNAMSAT-2 is nearly complete, waiting for a chance to become an OSCAR (Orbiting Satellite Carrying Amateur Radio).

Dan Schultz N8FGV delighted the audience with his pictures from the Hubble Space Telescope. Dan showed several new and exciting images from the telescope taken after the Shuttle repair mission. He had a few picture copies which were included as handouts for those attending.

Bruce Paige KK5DO finished the Friday talks with his description of the efforts in Houston to get the local Houston Area AMSAT Net out to as many hamsat enthusiasts as possible via commercial geostationary satellite link and HF. The Houston net can be heard every Sunday night at 10 p.m. Central time on Telstar 302, Transponder 21, 5.8 MHz audio subcarrier or on 1860 kHz am from Missouri. Many VHF and UHF repeaters in North America also carry the net via the satellite feed.

Photo B. AMSAT VP of Engineering, Dick Jansson WD4FAB, coordinated the Phase 3D talks at the AMSAT Symposium.

Saturday

Activities began in earnest at 8 a.m. AMSAT President Bill Tynan W3XO gave an official welcome to the symposium participants.

With the scheduled launch of Phase 3D only a year away, the focus of the symposium was on the new satellite. AMSAT VP of Engineering Dick Jansson WD4FAB moderated the morning talks, all dealing with progress of the Phase 3D program.

Project Leader Dr. Karl Meinzer DJ4ZC brought participants up to date on launch opportunities, financial considerations and an overall picture of the program. The planned launch is to occur late in 1996 on the second flight of an Ariane 5 vehicle. If there are difficulties with the schedule, the satellite may be launched as late as mid-1997 on an Ariane 4 rocket. Phase 3D is on schedule, but still needs more money to pay for launch costs and the many other items that come with any launch campaign.

Most of the mechanical efforts for Phase 3D are the responsibility of AMSAT-NA (North America). Dick WD4FAB presented details on the structural and thermal design, while Stan Wood WA4NFY followed with antenna location and other considerations. It has been quite a challenge to orient the spacecraft antennas on one face of the satellite without causing interaction problems.

AMSAT Board of Directors member Dick Daniels W4PUJ related information on the propulsion system. The satellite has a kick motor similar to the previous Phase 3 satellites, but it also has an ammonia arc-jet motor that will be used for many months during final "tuning" of the orbit. The plumbing for the motors is in place and waiting for final wiring.

Lyle Johnson WA7GXD and Chuck Green NØADI

Photo C. Stan Wood WA4NFY and his cake-pan, 1.2 GHz backfire antenna.

Photo D. AMSAT Board member and past President, Dr. Tom Clark W3IWI, shows one of the L-band "salad bowl" antennas for Phase 3D.

characterized various Phase 3D computer systems. The main operations computer is called the IHU or Internal Housekeeping Unit. Other computers include the GPS system and the RUDAK digital communications controller.

Peter Guelzow DB2OS covered the Controller Area Network or CAN that will be used for digital communication between subsystems onboard Phase 3D.

AMSAT President Emeritus Dr. Tom Clark W3IW1 described his Global Positioning System (GPS) experiment for Phase 3D. Bdale Garbee N3EUA and his crew have been working on the GPS computer subsystems and writing software for use in the spacecraft. Bdale passed several prototype boards around the audience during his talk.

Hiroyuki Ohata JM3MAJ brought a prototype of the SCOPE digital color imaging experiment with him from Japan. His presentation provided details on the specifications of the two-camera unit. The

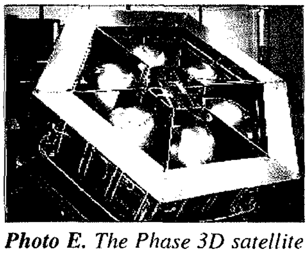

***Photo E.** The Phase 3D satellite is progressing well at the AMSAT lab in Orlando, Florida.*

***Photo F.** Integration Laboratory Manager Lou McFadin W5DID in the clean room with Phase 3D shows the location of one of the 12 magnetorquer rods to be installed.*

equipment will be located in the spacecraft with holes strategically located to allow the cameras, one wide angle and the other narrow, to view the earth at the orbit's high point or apogee.

AMSAT Integration Laboratory Manager Lou McFadin W5DID wrapped up the morning talks with data on the complex wiring harness for Phase 3D and methods now used in the lab to keep up with all the parts to be built into the 1,000-pound satellite. Lou joined the project after retiring from NASA at the Johnson Space Center in Houston.

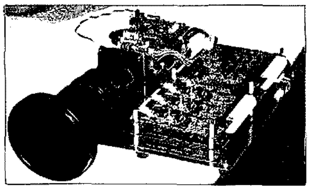

***Photo G.** A prototype of the Japanese SCOPE Digital Color Imaging Experiment camera was on display at the symposium.*

Afternoon sessions concentrated on future satellite programs. Peter Vekinis KC1QF/EI4GV got things started with ideas about very small satellites, or picosats. Measuring only five inches on a side and incorporating active three-axis stabilization, Peter proposed a constellation of picosats in low earth orbit, all using VHF and UHF frequencies. While still in the early planning stages, the program is thought provoking and may provide future satellite builders with ideas.

Steve Bible N7HPR discussed his efforts with the World Wide Web Amateur Satellite Ground Station. For those with Internet access, the address is http://gndstn.sp.nps.navy.mil

The system Steve created maintains data received from the 9,600-baud amateur satellite (UoSAT-Oscar-22, Kitsat-Oscar 23 and Kitsat-Oscar-25). Steve also gave an update on the PANSAT project sponsored by the Naval Postgraduate School in Monterey, California. Using spread-spectrum techniques, this small satellite is scheduled for launch in 1997 and will use the frequency range from 435 to 438 MHz for both uplink and downlink. Work has begun with TAPR to provide earth-station hardware and software to communicate with the satellite. Updates on the PANSAT project can be found via the Internet at http://www.sp.nps.navy.mil

SEDSAT Project Manager Dennis Wingo KD4ETA brought everyone up to date on the status of the SEDSAT program. SEDSAT-1 is a microsat-class satellite that will be part of NASA's Small Expendable Deployer System (SEDS). Changes in launch schedules have caused delays with this hamsat. SEDSAT will carry several scientific and amateur-radio experiments. The main purpose of the satellite is to test the dynamics of tethered satellites and remote sensing. The SEDSAT program also has a World Wide Web home page at http://seds.lpl.arizona.edu

Ken Emandes N2WWD completed the afternoon talks with an enlightening description of his efforts to properly identify the Russian RS-15 satellite and its orbit. Orbital data from NORAD and NASA

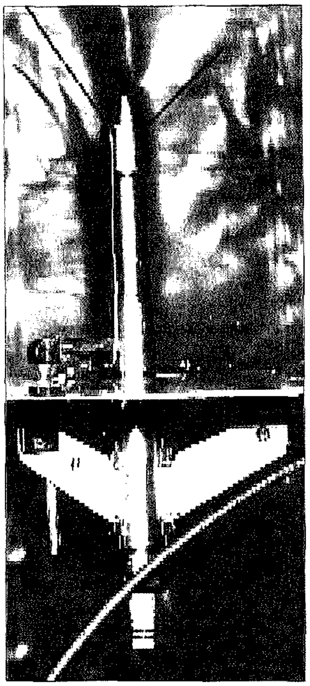

***Photo H.** The ammonia arc-jet motor will be on for several months after launch to fine-tune the orbit of Phase 3D.*

was inaccurate in the early days following the launch of the satellite. Ken determined that the upper-stage vehicle had exploded leaving many radar targets in the area of the satellite. Determining which space objects were nothing but debris, and which was RS-15 became a challenge. While NORAD used their sophisticated radar systems to catalog the objects, Ken used both the NORAD/NASA data in conjunction with the 10 meter ham-radio signals transmitted by RS-15 to characterize the orbit and identify the satellite.

After Ken's talk, AMSAT President Bill Tynan introduced the officers and Board of Directors' members. Each officer or director was given a chance to speak to the group. It was also a time for questions and answers from the attending AMSAT members.

Following a short break to allow everyone to catch their breath and relax after data input overload, the yearly banquet began. The speaker was Dr. Paul Shuch N6TX. Last year he talked about "The

Search for Dark Matter." This time he provided details about the SETI League. Paul is now the Executive Director of the organization and provided everyone with an informative, yet light, discussion on the search for extra-terrestrial intelligence. He has that unique ability to make the most complex topic both understandable and fun.

Bill Burden WB1BRE of the American Radio Relay League presented AMSAT with a check for $305,000. This was

Photo I. Stan Wood WA4NFY and Tom Clark W3IWI discuss one of the GPS antennas being prepared in the AMSAT lab in Orlando.

the result of the ARRL Matching Fund program run earlier in the year to help finance Phase 3D.

Prizes and AMSAT awards finished the evening. The prizes ranged from books, T-shirts and maps to gear from SSB Electronics, 50 copies of Windows NT from Microsoft, and a mobile transceiver.

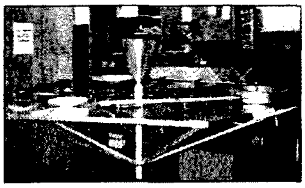

Photo J. A mock-up of the "earth" side of Phase 3D is used to test antenna locations in the lab.

Sunday

Following the Field Operations Breakfast at 7:30 a.m., Bill Tynan started the AMSAT Board of Directors' meeting,

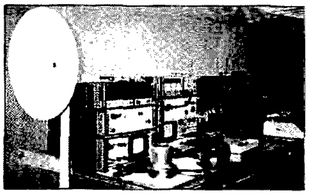

Photo K. One of the test equipment benches in the AMSAT lab in Orlando.

which lasted through mid-Monday with a few breaks for food and sleep. The agenda covered many items including publications, SAREX, the DSP project status, long-range planning, commercial relationships, new satellites and the budget.

The Phase 3D program was the main topic this year. AMSAT still has a significant challenge ahead to pay its part of Phase 3D and maintain other activities. Work on fund raising will continue to dominate AMSAT's operations until launch.

Parallel to Sunday's BoD meeting, guided tours were provided of the AMSAT lab facility at the Orlando airport. A chartered bus furnished transportation for those interested in viewing the progress on the satellite and improvements to the lab. Many displays and demonstrations were provided.

Tucson, Arizona, is the site for the 1996 meeting. It is sure to be a fascinating event since Phase-3D will be completed and waiting for launch. Don't miss the Friday talks. Be sure to come early. Copies of the *Proceedings* of the symposium are available from AMSAT or the ARRL. The book is 8 1/2" by 11", 182 pages, and softbound. It's well worth the cover price of $12.00. AMSAT can be contacted at 1-213-589-6062 for details on shipping charges.

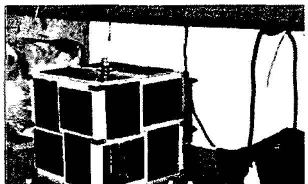

Photo L. A microsat model from five years ago resides in one corner of the AMSAT lab in Orlando.

Straight Key Night

For many years the ARRL has sponsored Straight Key Night (SKN) on New Year's Eve and New Year's Day. In

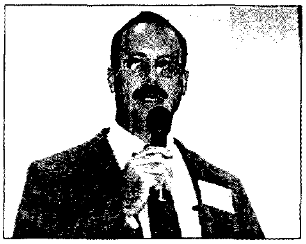

Photo M. Steven Bible N7HPR discussed Internet connections for satellite telemetry monitoring and future modes for digital satellite communications beyond Phase 3D.

1972, a group of satellite chasers decided to try their hand at some straight key CW via OSCAR-6 during SKN. The idea caught on and the tradition has been maintained whenever there has been a satellite available for the event.

AMSAT Vice President of International Affairs Ray Soifer W2RS invites interested satellite operators to participate in the 24th annual SKN via OSCAR. He reports that there are no rules, no scoring, and no need to send in a log. Just call CQ SKN in the CW passband segment of an OSCAR between 0000 and 2359 UTC on January 1, 1996, or answer a CQ SKN call from another station. Contacts via the moon also count. Nominations for best "fist" can be sent to W2RS@WA2SNA.NJ.USA.NA via packet or to W2RS@AMSAT.ORG via the Internet. You can also use his Callbook address.

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

I guess I should begin this month by paying attention to the date on the cover of the magazine, and wishing each and every one of you a *Happy New Year!* My most sincere wishes for a Healthy and Happy 1996 to all of my readers. With this interest in time, I have several items of interest to the ham paying attention to this detail of our lives.

To begin with, a new program has hit the market, called WinZones, billing itself as a "comprehensive time zone utility for Windows." Produced by Extend, Inc., in Pleasanton, California, the program generates a number of customizable clocks on the Windows desktop. It is available in versions for both Windows 3.1 and Windows 95, and I have reviewed the Windows 95 version.

As you can see in Fig. 1, the program's window can be filled by a clock, either analog or digital, which may be set to any time zone. A variety of cities are provided in a data file, which allows the generated clocks to highlight time zones around the world. The four clocks from my screen demonstrate the degree of customization possible. Clocks may be analog, using Arabic or Roman numerals, or digital. Typefaces, size, and color of the clock may all be changed at will. There is even an alarm function, indicated by the red arrow on the Jerusalem clock in the Fig. 1, that can be used for any purpose where an alarm might come in handy.

Indicators on the clock face indicate daytime or nighttime by a little tree in the sun or moon being displayed, and daylight savings time may be activated individually for each clock to allow for differences in daylight savings time observance in different areas.

The program installs easily, using the common "a:setup.exe" routine. It opens the Setup Wizard, which quickly steps you through the installation process. Although the program configures itself to open with four clocks, this is quite easily changed to whatever your heart desires. Additional clocks may be opened on the fly, so to speak, and closed again without affecting the rest of the program.

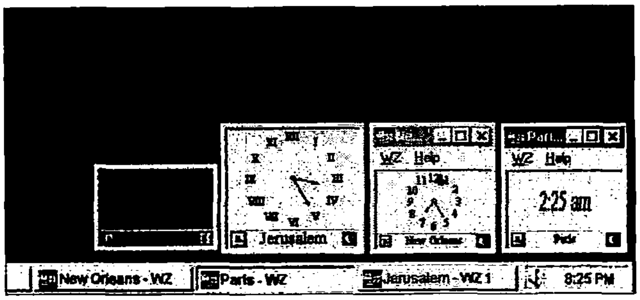

Fig. 1. A WinZones screen in Windows.

Unfortunately, uninstalling the program is not so easy. While there is an uninstall routine, as required of Windows 95 compatible programs, it fails when called, indicating that it cannot find the uninstall log file. Since all the files appear to be installed in one directory, erasing that directory effectively gets rid of the program. However, I cannot tell, at this point, if there are not some scattered INI files, pointers, or registry data remaining.

In short, if you have a need for several clocks on the screen at one time, WinZones may be just what you are looking for. Windows 95 comes with a clock of its own, on the taskbar. So, if you have no trouble converting from local time to GMT or the time zone of your current contact, this product may be overkill. If you are interested, contact Extend and tell them you read about it in "RTTY Loop."

Now, if all you want is an analog clock on the screen, instead of the little digital taskbar icon, check out rclock.exe, one of the "powertoys" from Microsoft. Available free on the Microsoft Home Page, as well as other bulletin boards near you, this little darling puts a round clock on your screen, through the magic of Windows 95's sophisticated windowing system. Of course, you can configure it to be a digital clock as well. While you can't use it to put multiple clocks on the screen, and it can only display the system clock time, it may be all you need. If you want this little darling and can't find it in your neighborhood, I wouldn't be surprised if it didn't turn up on a RTTY Loop Software Collection disk, real soon!

With all these clocks, you might want to know what time it is — for real! That need takes us to our web site of the month, a page which will give you the correct time, down to the fraction of a second, direct from the U.S. Naval Observatory Master Clock. Point your web browser to: http://tycho.usno.navy.mil/what.html and you will see a Daliesque graphic and a button to push. Pushing the button will give you a spread of times from a variety of sources. Given the delays inherent in the communications system, I would not calibrate a clock to the hundredth of a second, but it is more accurate than that sundial in your backyard. Enjoy!

Albeit a bit late for some of you, my apologies to anyone I have kept waiting for either a list of programs or software collections. While I would like to spend most of my day on ham radio or computers, the demands of my practice, family, and other pressures occasionally delay my responding to your inquiries. By the time this column is published, I should be pretty much caught up. If you have been waiting for my response for more than a month or so, feel free to drop me a line, I may not have received the original request.

Work is progressing on setting up a RTTY Loop Home Page on the web. Stay tuned, by the time this column is published it may well be online. Try one of the search engines and see, you might be surprised. In the meantime, the RTTY Loop Software Collection continues to grow. Get the latest list by sending a stamped, self-addressed envelope to the address at the top of the column, or by E-mail to me on America Online (MarcWA3AJR), CompuServe (75036,2501), or via the Internet (marcwa3ajr@aol.com). Then again, if you're lucky, maybe you'll be able to download it from a home page yourself!

Mail Call!

This month, I'd like to devote the column to answering some questions. Keep those letters coming, folks, but please don't include SASEs; I just can't answer letters personally. Those relevant to the column will be discussed here in the magazine. Here goes:

Dear Kaboom,

I recently bought a Radio Shack DX 390 receiver and am now thinking about greater involvement in ham radio. I was excited by your article in which you discussed how computers can be integrated into one's shack. I have a Mac Plus with 4 Megs of RAM. How are computers actually used in ham radio, and what kind of software is available?

Getting My Feet Wet

Dear Wet Feet,

The computer has loomed as the greatest advance in ham radio since sideband and FM came along. How do we actually use computers? Lots of ways! They depend, though, on what facets of ham radio intrigue you. You mentioned you were interested in CW and packet. Packet is, of course, a computer mode right from the word "go." In packet, you can use your computer as a terminal for a separate hardware TNC (terminal node controller—the thing that actually makes and decodes packets), or you can save some money and use the computer as the TNC itself. That's how I do it here, because it saves me the cost of a TNC. Several "software TNC" programs which let you do that are available for the PC, and there's at least one for the Mac. Some of the PC programs are Baycom, Soft TNC, and Poor Man's Packet.

[*See "Packet on the Mac," in the October '92 issue of* 73. *In the article, KD6CMT mentions a Contol Panel called SoftKiss which emulates a TNC in KISS mode. KD6CMT suggests using it in connection with NET/Mac, available through America Online and other online services. Reprints of the article are available for $3.00.—ed.*]

Using a computer as a TNC requires adding a small modem. You can buy one for about $50 (considerably less than the price of a hardware TNC), or you can build one, which will be a nice introduction to the technical side of the hobby. I built mine for about $20, and it works fine.

As for CW, there's all kinds of public-domain software that will help you. You can get study courses with audible practice drills. You can also get programs which will actually key your rig and send CW, and some can even receive it pretty well, showing the decoded characters in plain language on your screen! Truthfully, though, CW is not the most machine-friendly mode; if you practice, you can learn to receive Morse more accurately than a computer can. Besides, it keeps your skill up. I do have both transmit and receive on my CW program, but I never use the receive. Still, the transmit function saves a lot of wear and tear on my arm, and lets me send better code than I could with my iambic keyer. It's not as much fun, though.

If you get into contesting, logging programs can help you avoid dupes (duplicate contacts with the same station). And, when you're done, you can have the machine print out your logs, ready for sending in for your awards. I don't care for contesting, so I don't use anything like that. But, many noncontesting hams still like logging programs, simply because they make it easy to keep track of contacts. It's quite nice to answer a CQ ("calling anybody") and call up notes regarding the last contact with the same station. The other ham will sure be surprised when you say, "Hi, Bill, how's your dog's arthritis these days?"

If you get a CD-ROM drive for your Mac, you can install a callbook database that'll let you look other operators up by their callsigns. Especially if you want to QSL (exchange reception report cards), that

can save a great deal of time and effort on the air, because you don't have to exchange addresses.

Particularly because you're just getting into the hobby, you'll find your computer very useful as a study aid. Any ham-oriented BBS should have lots of exam simulators and study guides to help you earn your license. Good luck, and I hope you're on the bands soon!

Dear Kaboom,

The schematic in your article for the Kenwood MC-85 microphone modification did not show the resistor numbers for the 22k and 4.7k resistors. Also missing is the capacitor number for the cap between IC1 pin 2 and the 22k resistor. I'd like to modify my mike to work like yours, but I can't figure out the conversion without those numbers. Can you help?

Missing Info

Dear Missing,

Sorry about that! Somehow, those numbers got removed from the diagram. Here they are: The 22k is R9, and is connected between the wiper of the compression control (VR2) and IC1 pin 6. The 4.7k is R23, and is connected between one end of the same control and ground. And, the 3.3 µF cap is C8, and is connected between IC1 pins 2 and 6. Hope that helps.

Dear Kaboom,

I've been off the air for months, due to a failure of the MRF 485 driver transistors in my Kenwood TS-930. I was told that Motorola no longer makes these transistors. I tried a pair of NTE 236 transistors, which are listed as replacements, but they promptly failed. A Kenwood technician told me that the company does have a replacement transistor, but he no longer does these repairs. Also, there are other modifications necessary. Is there a retrofit?

Unwillingly Silent

Dear Silent,

My ECG cross reference lists these as ECG 236. I haven't heard about the retrofit problem, but it would pay you to try and get that Kenwood tech to send you the details of the required modification. Probably, it's just the addition of a capacitor or something similar. I suspect, though, that the NTE 236s failed for another reason. Most likely, both they and the original parts blew because something else is wrong. If I had to guess without actually seeing the radio, I'd wonder about your final transistors. Are you sure they're not shorted? Drivers usually don't go when the finals are good, and shorted finals will blow drivers faster than you can hit the "off" switch. Before investing in yet another pair of drivers, check those finals. Also, try RF Parts Company, (619) 744-0900, and see if they have any other replacements for the MRF parts. They carry all kinds of RF power transistors.

Dear Kaboom,

I enjoyed your articles on oscilloscope use. I picked up a scope at the last hamfest, but I don't understand one thing: when I hook my probes to the calibrator terminal, I get a nice square wave as long as the probe is in the X1 position. When I set it to X, though, the wave looks like something from outer space! It has big spikes at the top and bottom which then slope inward gradually to the end of the wave. Did I buy a hamfest nightmare?

Puzzled

Dear Puzzled,

Nope! Your scope is fine. It just watches the X-Files too much! Seriously, though, all that's wrong is a simple adjustment, and you don't even have to open up the case to do it. Take a look at your probe and you'll see a little hole with a screwdriver adjustment slot in it. Usually, it's on the part you hold, but it may also be on the part that plugs into the scope. This adjustment sets the capacitance of the probe when it's in the X10 position. Due to the very high input impedance of about 10 megohms, the amount of capacitance has a great effect on the resulting waveform. Just set the probe to the X10 position, connect it to your calibrator, and adjust the probe's trimcap until the waveform straightens out. You'll find that if you then use that probe on the other channel, you'll have to readjust it; that's how critical that setting is! By the way, that's why calibrators have square waves, instead of just supplying calibrated DC voltages with which to set the channel gain.

Until next time, 73 from KB1UM.

Another Potpourri

Several times a year I clean up my "in box" and take on a few topics that are not worth an entire column, but are of interest to readers because most of the ideas came from questions or comments in my mail box. Which brings up a little housekeeping matter. You can reach me at my post office box (P.O. Box 1099, Falls Church, VA 22041), or by Internet E-mail at carrjj@aol.com

Science Fair Project for a Radio Buff?

One of the topics that I've written about extensively over the past five years is what I call "radio science observing." This coined term refers to radio astronomy, propagation observations, and VLF SID (sudden ionospheric disturbances) hunting. The latter requires a VLF receiver, which can be built using low-cost components. VLF SID hunters look for the effects of solar flares on the ionosphere.

Because the distance between the Earth's surface and the bottom of the D-layer of the ionosphere is only a few wavelengths in the 15 to 30 kHz band, a sudden increase in ionization (as occurs during a flare event) causes that space to act like a waveguide at VLF frequencies. A friend of mine uses a geiger counter to record solar flare events. He looks for sudden increases in background radiation levels. It might be interesting to look for solar flares using both the VLF receiver and the geiger counter, and note what correlations do or do not exist.

If you do not own a VLF receiver, and are not inclined to build one, then you might wish to consider using the shortwave bands. The HF shortwave bands are not the best bet because there is a lot of variation in those bands under the best of circumstances. But you can make some recordings using the apparatus described below.

The trick is to monitor a station that stays on the air most of the time. The National Institutes of Standards and Technology (NIST) radio stations WWV (Colorado) and WWVH (Hawaii) are pretty good bets. Try monitoring the 5, 10, or 15 MHz signals.

Recordings can be made with either a strip chart recorder (which can be obtained relatively cheaply on the used market), or by using an A/D converter feeding a receiver. Although A/D converters were once expensive toys, one can now buy them relatively reasonably. There are models that will plug into the parallel printer port on the back of your computer (yep, that's what I said...the parallel port). These devices use the four bidirectional handshaking lines to take in the A/D signal. Others are available that will plug directly into the RS-232 serial communications port on the back of the machine. Radio Shack now offers a digital multimeter that contains a computer interface, and the software to drive it. This meter can be used as a data acquisition A/D converter.

Doing radio science observing may seem like a waste of a computer, but today you can buy non-Windows PCs for a song and a heartbeat. I've seen 286 machines sold for $10 by a local hospital that had just upgraded to 486-DX4 machines. The used ads, hamfests, and local used computer stuff stores can sell an '80s vintage PC-XT class machines for $50 to $100, and 286 machines for a bit more. I recently bought a 386-33 machine at a local used computer stuff shop for $200 complete with monitor. So, as you can see, setting up a monitoring station need not be terribly expensive.

Fig. 1 shows the circuit needed to obtain a DC signal that is proportional to the signal strength. Of course, if you can get to the receiver's automatic gain control (AGC) signal, then use it. But that's not so easy as it was when I was a Novice, so many readers will want to opt for the circuit shown in Fig. 1.

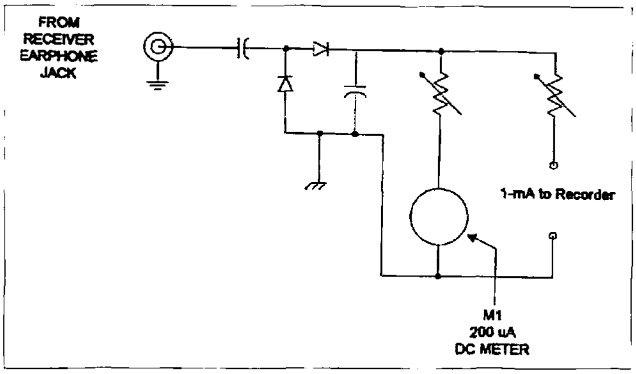

Fig. 1. Audio-to-DC converter for recording signal levels.

This circuit has two parts: a rectifier and an integrator. The rectifier is a voltage doubler type that uses two capacitors and two diodes. The capacitors are each 10 µF units (the straight line side being positive), while the diodes are 1N60 germanium signal diodes. That may surprise you in this silicon era, but those 1950-type diodes are preferred in this application because of the lower voltage drop (0.2-0.3 volts rather than 0.6-0.7 volts) compared to silicon diodes. Radio Shack and other sources still offer 1N34 and 1N60 diodes, usually in a blister pack of about a gozillion diodes for a few bucks.

The integrator produces an output that is the time average of the input signal, so it tends to smooth out very short variations in the signal (e.g., noise spikes), leaving the signal strength variation component. There are actually two methods of "integrating" this signal in this circuit. First, the action of the output filter capacitor, which is also part of the voltage doubler circuit, tends to smooth variations. The second factor is the inertia of the meter movement and the recorder pen assembly.

Levels to the meter and (if you use it) the 1-mA recorder assembly can be controlled with potentiometers. I found that signals' levels are generally sufficient to use nearly any potentiometer from 10k to 100k. In my case, I had a pair of likely 25k linear taper potentiometers, so I pressed them into service.

By the way, if you or some youngster you know is busy with the science fair activity in their school, then you might want to provide them with a copy of my book *The Art of Science* ($19.95, HighText Publications, P.O. Box 1489, Solana Beach, CA 92075; 1-800-247-6553). The chapter on winning science fairs is worth the price of the book alone. Besides, the rest of the book will tell them how to do science and how to handle data.

Bill Orr W6SAI, whom any honest technical writer today will recognize as the guru of gurus, was extremely complimentary in a review of the book in another ham magazine. He was especially enthusiastic about the chapter titled "Counterfeits of Truth," which deals with the logical fallacies. If you have any interest at all in intellectual honesty, then you might want to bone up on the fallacies...and compare with the news media and our politicians.

Low-Pass Filters

A low-pass filter (Fig. 2) is needed by nearly all ham operators who use the HF bands. Harmonic energy from our transmitters will clobber other services, notably television and FM broadcast radio bands (those frequencies that are harmonically related to the ham band frequencies). For transmitter harmonic suppression we would usually want to simply buy a 300-watt or 2,000-watt low-pass filter and be done with it. Those filters have a cut-off frequency between 30 and 40 MHz, so offer a substantial amount of attenuation in the 54-MHz, and up, band occupied by the television stations.

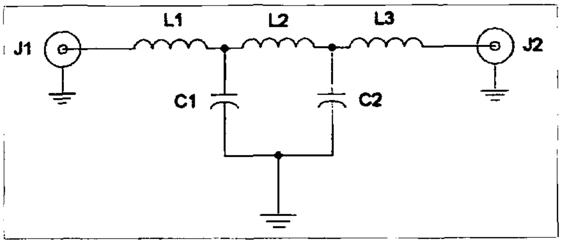

Fig. 2. Low-pass filter circuit.

But what do you do if you want to make a filter for another frequency? For example, suppose you wanted to build a 3-kHz audio filter for use as at the input of the speech amplifier in a transmitter, or at the output of a direct conversion receiver. Well, you build a circuit such as Fig. 2. One way to design your own filter is to look for a "normalized" design, and then frequency scale it. Such filters will show the values for some frequency such as 1 Hz, 1 kHz, or 1 MHz, and then you scale it by dividing the printed component values by the actual 3 dB cut-off frequency you want. That's the way my "FilterMaker" software works. Crude, but you get results.

But what do you do if you don't want a 50-ohm filter? Most of the tables published are for filters that have 50-ohm input and output impedances, which is the standard for RF systems. But in those audio cases mentioned above you might prefer to use 1000 ohms rather than 50 ohms. Also, if you design circuits for the NE-602 chip, you can avoid the use of impedance transformers at the input and output terminals (pins 1/2 and 4/5, respectively) if you go ahead and design the filters for the 1,500-ohm impedance offered by the NE-602 device, rather than 50 ohms.

The 1996 edition of *The ARRL Handbook for Radio Amateurs* holds the solution for you. On page 16.6, the circuits for both capacitor input and inductor input low-pass filters are shown, along with the table for the 1 radian/second, 1-ohm capacitor and inductor values. You can use the equations shown in the article to calculate the values needed for the specific frequency and input/output impedances that you need for your application.

The *ARRL Handbook* has a software diskette accompanying it which makes the calculations a little less tiresome for those for whom a first course in high school algebra was more traumatic than using up a little hard drive space.

It came as a bit of a shock when I ordered the *Handbook*. It's been a couple years since I bought a copy, so I was a little taken aback by the $38 price tag. That's more than ten times the price I paid for my first *ARRL Handbook*...which dates me a bit, doesn't it??? You can get the *ARRL Handbook* from local ham stores or from the Uncle Wayne's Bookshelf (see ads in this magazine). 73

Energizing Experiments

There are lots of obvious good reasons for including a unit on energy in your ham radio curriculum. While lining up my guest speakers for my classroom this term, I decided to invite a spokesperson from our local electric utility, Con Edison. Guest speakers are always a good idea. They bring a change of pace and face for the youngsters, or to whomever your daily audience is. We wound up having several assembly programs being given so that other children besides the ham radio students could benefit from the visit. Here are some of the experiments the children seemed to enjoy the most.

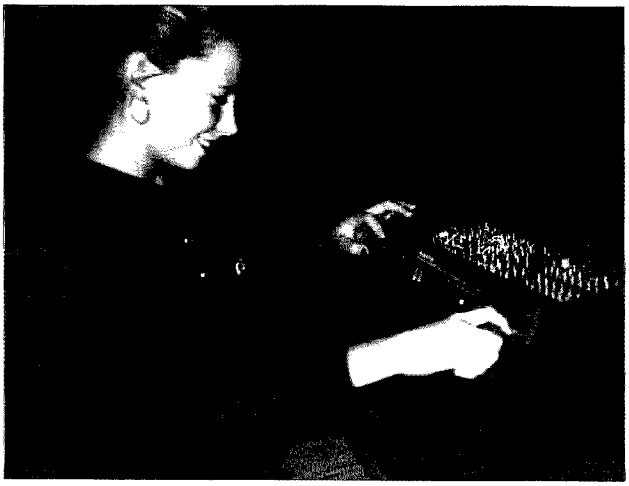
All of us know that energy is a big part of our lives. Scientists define energy as the ability to do work. There are many forms of energy; for example, there are heat, light, electricity, movement of air, water, and machines, and gravity (the earth's pull). There are many sources of energy; for example, there are fossil fuels, hydropower, nuclear power, and solar power. Sheets of paper were distributed for the students to list the ways in which energy makes their lives better. It was pointed out that some energy sources are limited and costly. That's why conserving energy is so important. After the experiments were completed, the children were asked to add to the list they had made.

The first experiment dealt with conduction. The materials needed are: hot water, shallow pan, metal spoon, wooden spoon, plastic spoon, and a glass rod or tube.

Background:

Heat is an important form of energy in the home. Heat is "molecules in motion." Molecules are particles that are too small to see with the eye. All things are made of molecules. They move back and forth slowly at cool temperatures—faster at warmer temperatures. Heat can move by conduction—heat passing directly from one thing to another through touch. Convection is when something heats air (through conduction), which then rises, carrying the heat elsewhere. Radiation is invisible "heat rays" which carry heat away from something. (No touching of objects or movements of air is needed.)

Homes, schools and other buildings lose heat in cold weather, and gain heat in hot weather by conduction. Heat is "conducted" through walls, doors, windows, etc. In this experiment you'll "feel" conduction at work.



Many spin-off lessons come after a guest speaker has visited a ham radio classroom. Here's Kristy, 8th grade.

Procedure:

1. Pour about 1 inch of water in the pan.
2. Place the spoons and the glass rod or tube in the hot water. Which object do you think will become the warmest?
3. After 2 minutes, remove the objects from the water. Which one feels the warmest? Which one feels the coolest? Children were asked to explain why on their papers.

Hands-on experiments can be "energizing." This is Mohammed, 7th grade.

This was a really simple experiment designed for lower grades. Of course it can be adapted for older classes accordingly.

How To Figure Electricity Costs

The next activity led to several spin-off lessons in math and science. "How To Figure Electricity Costs" brought us many favorable comments from the parents. Materials needed: classroom lighting information (wattage and number of bulbs in the classroom).

Electricity is a form of energy used widely in homes, schools, and other buildings. Choice and use of lighting and appliances affect electricity costs. This experiment will give you a rough idea of how electricity costs are determined.

Procedure:

1. Find out how many light bulbs are used to light your classroom.
2. Find out how many watts of electricity each bulb uses. (More watts means more electricity is being used.)
3. Total the watts. Be sure to include the watts for each bulb.
4. Divide the total by 1000.
5. Multiply your answer by the average number of hours the bulbs are left on during each school day.
6. Multiply your answer by the number of school days in the year. This will tell you roughly the number of "kilowatt-hours" of electricity the lights will use in the school year.

If each kilowatt-hour costs 10 cents, about how much does it cost to light your classroom for the year? Can you think of two ways to cut lighting costs in school and at home?

The students enjoyed running all over the classroom, jotting down the wattage information. More importantly, it made them aware that there is a real cost to consumption of electricity. 73

Tattooing Yaks

Well, another new year. It's a perfect time to start new projects, and plunge into the unknown. John N8ZXB and Scott N8JSK have taken up tattooing Yaks. A rewarding and highly satisfying hobby—as Scott calls it.

I am not into Yaks, but I do like to play with digital panel meters. In the past, I've mentioned the DI International DPM5035L as a rather diverse DPM. So, to start out the new year, I'll show you what I've been doing with this meter.

Instead of displaying a voltage obtained from a power source, I've been trying to marry the DPM to a microstrip RF pickup. Up to a certain point, I've been making some progress. Here's the basic idea.

The first thing required is some way of picking off a small amount of RF coming out of our rig. I have been working on several methods, but the stripline seems to work best for me. In fact, my first attempt was in using a defunct CB SWR meter. It had the proper power capacity and the meter had a microstrip already in place. Instead of using PC board copper traces for the actual micro lines, the CB SWR meter used two large copper wires placed in parallel to a single conductor carrying the RF from one connector to the other. It required only a few cuts with the side cutters to remove the unwanted parts. I kept the metal case and added some .001 feedthrough capacitors between the RF section and the digital section.

The diodes used in the original meter were 1N914s. I replaced them with two hand-selected 1N34As. Better diodes are available for this purpose, but I had those guys in hand.

The DPM has a input impedance of over 100 megohms, so loading of the sensor would not be a problem. A two-position switch allowed me to select either the forward RF position or the reflected power position. The meter will not read out SWR, but rather the voltage generated by the forward RF and the reflected voltage caused by any standing waves on the feedline and antenna. To read the actual SWR, a graph would need to be constructed to show the voltage generated by the reflected RF. Of course, the voltage would only be correct at a specific RF output. This is something I have not done. Common sense should instantly tell you the higher the reflected voltage the higher the SWR is on the antenna system.

Problems

Even with an input of 200 mV, the resulting voltage developed by my QRP rig, did not generate enough for a large reading. The reflected reading was even weaker, as it should be.

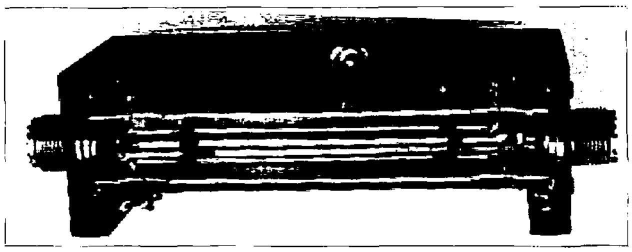

Photo A. Michael Bryce digital panel meter with microstrip RF pickup.

Looking back, the microstrip is probably not the best thing to use at HF frequencies. Instead a toroid pickup would be better. I could modify the transformer's secondary to increase the resulting voltage generated by the RF passing though the core. I also figured the toroid would be more frequency tolerant.

I ended up using an RF pickup from a an old project I had laying around. I used one of many classic RF sensor projects, many of which are in the *ARRL Handbook*. My pickup will generate both the forward and reflected voltage generated by the RF flowing through it. Everything goes inside a deep drawn aluminum box. All leads leaving the box go through .001 feedthrough capacitors, which I might add, are getting harder to come by.

Once the RF sensor had been built, the next step is to increase the voltage developed by the sensor to a usable level needed by the DPM. To do that, I used an op-amp as a voltage amplifier.

Having spent most of a Saturday night working on the the voltage amplifier, I found that the popular 741 op amp did not provide a low enough offset with no signal. So, a LTC1001 op amp by Linear Technologies was put into use. An OP-07 op amp may also be used, but are much harder to come by. Digi-Key stocks the LTC 1001. The LTC1001 is about $2 a pop.

Instead of sweating blood trying to come up with a dual-voltage power supply, I cheated and used two 9-volt transistor batteries. A third battery is used to power the DPM. This DPM must have its own power source. A junk box 3PDT switch is used to turn off the project. If you don't happen to have a 3PDT switch, just leave the DPM on as it should operate for the shelf life of the battery. That's not the case with the op amp circuit.

Projects

In Photo A, you'll see the final result of my work. Again, let me state this is *not* a finished project. There is enough information for you to pick up where I have left off. This is not the last word in a digital SWR meter by any means.

I have also tried to add the second circuit to the DPM. Rather than reading the voltage produced by the RF sensor, I tried to make a digital field strength meter. In its simplest form, the meter will display the resulting voltage developed by the detector. Again, an op amp is used to up the voltage to a more suitable level.

Notice, the field strength meter has no tuned circuits. In fact, it has a response from DC to light. By adding some tuned circuits, one should be able to sniff out RF on a very narrow frequency range. If you like twisting knobs and dials, then insert your tuned circuit before the detector and the antenna. Use shielded coils to prevent unwanted pickup from coil to coil. Digi-Key stocks a large assortment of RF coils in their catalog. A plastic AM broadcast 365 pF variable capacitor from a defunct transistor radio would make an ideal capacitor to tune the circuits into resonance while keeping the size of the field strength meter down.

There is still one more project I wanted to try with the digital meter but have not had the time. I wanted to measure the voltage developed across a dummy load and then display the result. In theory, it should work. In Fig. 1, a simple RF detector, will convert

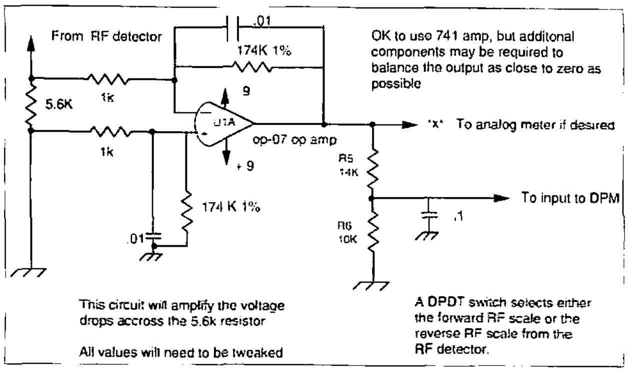

Fig.1. Schematic of the DPM.

Welcome Newcomers

Wayne Green W2NSD/1

When I saw the FCC's license figures for the last 10 years I could see that we'd had a substantial increase in Techs, hut it wasn't until I drew the graph you see here that I grasped the full extent of what has actually happened. Check it out and let the message sink in.

The graph explains several things: (1) Why hamfest attendance has dropped so much in the last few years; (2) Why our ham dealers and manufacturers are really hurting for sales; (3) Why our ham bands seem less crowded than they did 30 years ago.

The General Class license numbers have increased at about 1.1% per year over the last 10 years. But when you consider that the FCC admits that over 40% of the old licensees are not renewing when their tickets expire, that looks like a possible loss of 4% per year! The obvious fact is that the no-code Techs, with pitifully few exceptions, are just not interested in upgrading. Our repeater system is much better than the 40 channels of CB, and that's all they seem to want in life.

And that means that *Radio Fun* has failed in its mission. We haven't been able to sell the current newcomers on the great fun amateur radio provides via satellites, building kits, packet, ATV, SSTV, RTTY, DXing, DXpeditions, foxhunting, ham clubs, and so on. I don't run any of my businesses just to make money. They all have a mission, so I'm discontinuing the publication of *Radio Fun*. Maybe this will allow me to spend more time pushing cold fusion, which has a far greater potential for benefiting the world.

Can anything be done to blast these ex-CBers off 2m and into General tickets? I'd like to see some

> ***"Get on from there and work 10,000 J's in a week, and you'll see what good operating sounds like."***

clubs make an effort to (a) get these guys to come to club meetings; (b) provide them with upgrading classes; (c) send me photos of their graduating classes, along with stories on how they did it.

We can't win this by hassling the Techs. Ridicule won't work either. What we have to do is get them interested enough in what the HF bands have to offer to get them to go for a General or Advanced ticket. That's why I've been harping about our setting up crossband repeaters, making club meetings more fun, getting some zing into the club newsletters with reports on what hot DX some members have worked recently, and anything else exciting that the members have been doing.

I get a lot of club newsletters, but I don't recall seeing one with a request from the editor for the members to write about anything exciting they've done in the hobby. Amateur radio has provided a lifetime of excitement for me, which I try to share with you. If I can get on the air from South Yemen, so can you. It didn't cost me anything because I kept my eyes open and grabbed the opportunity when it turned up. I keep asking you not to just enjoy life's merry-go-round, but reach out for that brass ring. You can get it, but only if you really reach.

When I started *73* I put every nickel I had into the first issue. I didn't start out rich. I wasn't a great student in school. Heck, I just barely made it with C's. It was ham radio that pushed me to go to a technical university. It was ham radio that got me into the Navy as an electronic technician. Later a RTTY chum got me a job on a Guggenheim grant, working on a color organ. And another RTTYer got me a job as the head of the Music Research Foundation. My hamming got me into broadcasting as an engineer-announcer, and then into TV as an engineer, cameraman, then a producer-director. It was RTTY that got me into publishing.

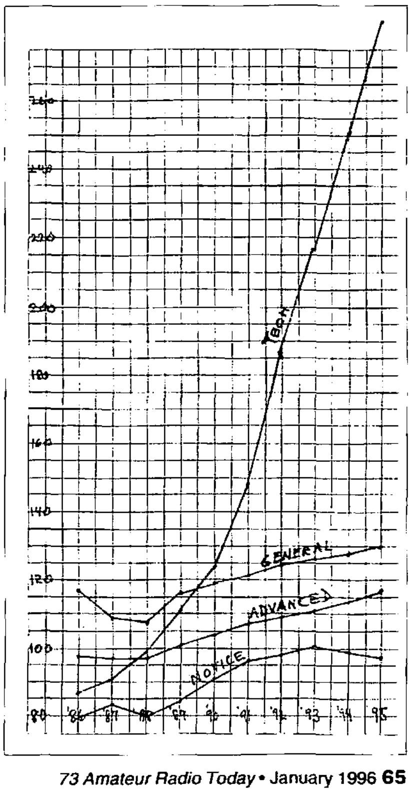
We know that the key to making money lies in technology, and we also know that hamming makes it fun to learn about electronics. As transportation costs drop and communications systems improve and get cheaper, unskilled people in America will be more in direct competition with unskilled workers in the lowest-wage countries of the world. So we're going to see more and more of a difference between what educated and ignorant people earn.

I do get upset over the bleeding heart liberals taking my money and giving it to people who spurned the free education they were offered, thereby guaranteeing themselves poverty unless they go into crime. Grumble.

I want to read in club newsletters about the clubs descending on their local schools like locusts and getting the kids interested in hamming. I want to see them never-say-die on getting the new Techs in their area to upgrade.

I'd hoped that I could make a difference with *Radio Fun*. The hams I did get to subscribe liked it a lot. I think we had one of the highest percentages of renewals in publishing history. But, as I explained, I've never had any interest in doing something just because it makes money. If it isn't going to somehow be a benefit to mankind, the heck with it.

Look, the ARRL obviously isn't going to do anything about this, and I've failed, so it's all up to you. Start seeing what you can do to get these Techs to upgrade and have some fun with us on the low bands. Get 'em on packet, satellites, or maybe a DXpedition to South Yemen. It's been a while since I operated from there. Or perhaps New Caledonia, where the local hams are very friendly and will lend you their stations, so you don't even have to carry your rig and antennas along. Get on from there and work 10,000 J's in a week, and you'll see what good operating sounds like.



the RF across the dummy load and then output the result as a DC voltage proportional to the input. The old Heathkit Cantenna has such a circuit built inside a small box mounted on the dummy load lid. As a matter of fact, I plugged into the output jack of my Cantenna and was able to display a reading on the DPM. Again, a graph could be made to compute the number displayed on the DPM into something more useful. Or, if you wanted to get really mad and wild, a small embedded microprocessor such as the PIC 16X series could be programed to convert the incoming voltage into something really useful on a LCD display

For those of you who want to experiment with the digital SWR meter, I have some of the D1 International DPMs in stock. They're $30, and that includes first class shipping. Send to my attention at the address at the top of the column.

Major Project Plus New Rig

As I write this, I am about to undertake a major project—cleaning off my work bench! For sitting on a table in the next room is a TACP1 by S&S Engineering. This rig is the first synthesized QRP transceiver to come from S&S Engineering utilizing a tuning knob for frequency selection. This is the second version of the TACP1. The first model was available only on the 80 meter band. There is now a TACP1 for 40 meters, the bread and button of most QRPers. Stay tuned for a full-blown review of this exciting new rig.

Communications Simplified, Part 1

Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

If you're into ham radio, then you are already into electronic communications as well. But if you are a beginner, or if you've limited yourself to contesting or chatting on your local repeater, you've probably missed out on a lot of the more interesting technical parts of communications. This series of articles will try to bridge that gap, but in a simple (and hopefully interesting) way.

These articles are the result of a community college course I have been teaching for some years. Since I haven't been able to find just the right textbook for my course, I've decided to write my own course notes. Eventually, these notes will become a textbook, but for now you're looking at just the notes.

But don't be scared by the idea that this comes from a college course—it isn't as complex as you think. First of all, I teach a survey course. That means that it's an introduction to communications for students who haven't taken any other communications courses before. So it starts fairly simply, and doesn't assume a lot of previous knowledge. In those areas where it assumes some knowledge from a prior course, or where it seemed like a good idea to discuss some related topic, I've inserted what I call "detours"—short discussions that temporarily break away from the main subject.

Second, I teach a survey course that tries to cover a big area in just one semester. That means that there isn't time to go into tremendous depth on any one topic. Hence, we have to stay fairly simple at all times. The course has a lot of descriptions and pictures, and almost no math.

Third, this is a community college course in the second year of a technical program. It's intended for students who will become technicians, not engineers or mathematicians.

Finally, Wayne has made me promise not to show off with fancy formulas and theorems, and to add a little sugar to make the material go down easier. (I guess that means I have to crack a bad joke now and then, such as "What do you get from a Mafioso college professor? An offer you can't understand!")

But before I start off, let me add a little fine print for the benefit of the many readers who probably know a lot more about this subject than I do. Please keep in mind that these articles are intended for beginners. As such, I will often provide explanations that may seem a little (maybe *very*) simple-minded to you. While my explanations will not be *wrong*, they may be very *incomplete*. Please don't barrage me with long treatises and reprints from other texts and journals if I've omitted or simplified too much (but do let me know if I say something that isn't true).

So let's get started.

Communications

Communications is simply the moving of information from one place to another.

An English teacher thinks of communications as the process of writing or speaking words, which tell your reader (or listener) something you want him or her to know. There is even something called mass communications, which is sort of like journalism, but for TV, radio, and film. In this course, on the other hand, we think of communications more as the electronic process and equipment needed to send information over long distances.

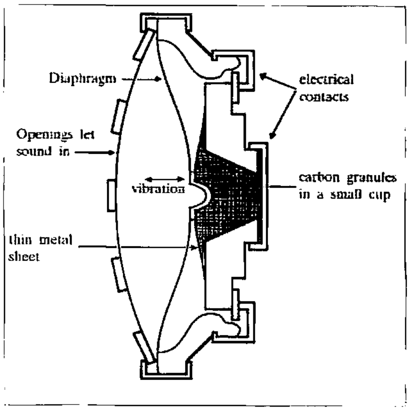


Fig. 1. Telephone-type carbon microphone.

For our purposes, we are interested in three aspects of communications:

- What is being sent? In other words, what kind of information are we sending; is it sound, pictures, or perhaps computer data?
- Through what is it being sent? That is, what is the *medium* through which it goes—wire, radio waves, sound, light, fiberoptics?
- How is it being sent? All by itself as in a telephone wire, or combined with other signals? Analog or digital?

It would be nice to be able to look at each one of these questions separately. Unfortunately, they all interact, and so our discussion will have to flit back and forth occasionally. Still, let's try to start with an orderly approach.

Let's start off with what is being sent. The information you send can be sound, video (pictures), or digital information. Let's look at each in turn.

Sound

Sound is simply the vibration of air. When we speak, our vocal cords vibrate the air coming out; the sound travels through the air until it vibrates the ear drum in someone's ear, which eventually winds up in sending nerve signals to that person's brain.

In electronics, a microphone is used to convert the air vibrations into an electrical signal. The air vibrations move a thin metal or plastic plate

(called a *diaphragm*) inside the microphone; a motion-to-electricity converter then converts the motion into an electrical signal. This signal is amplified and somehow sent from one place to another, and then converted back into air vibrations by a loudspeaker. Both the microphone and the loudspeaker (more often just called the speaker) are called *transducers,* a term describing any device that converts energy from one form (such as mechanical vibration of the air) into another (such as an electrical signal). (See Detour 1.)

In simple sounds such as someone whistling, the resulting waveform may be a sine wave; in more complex sounds the waveform may be much more complex as well.

Let's now look at the output of a microphone on an oscilloscope. What you see depends on the sound that the mike is picking up.

Suppose you stand in front of a mike and whistle a pure note into it (making sure to be far enough away so the mike isn't picking up the sound of the air hitting its front). You'd see the signal shown in Fig. 4. This kind of a wave is called a *sine wave* because of its relationship to the sine function from math.

On the other hand, suppose you whistle another note, but this time an octave higher. The word *octave* is a musical term, meaning eight white keys lower on a piano keyboard. This time you'd see the waveform of Fig. 5.

Both of these waves have the same shape, but the second one goes up and down twice as often as the first. In electronic terms, its frequency is twice as high. More on this in a moment.

Now suppose you do the same thing, but this time look at the signal created by the sound of some instrument such as a trumpet, rather than a whistle. Fig. 6 shows the resulting picture.

The sound in Fig. 6 has the same frequency as that in Fig. 5 (since it has the same number of cycles in a given time period), but it looks very different. A musician might say that it has the same *pitch* (that is, it is the same musical note), but different *timbre* (a different sound quality). Some repetitive sounds (like the pure tone of a flute) have a waveform almost like a sine wave; other repetitive sounds (like those from a violin or trumpet) have a waveform possessing a basic frequency, but which looks much more distorted and "kinky" than a sine wave.

The frequency of a note determines the pitch; two different instruments playing the same note have the same frequency. But they sound different because their waveshapes are different. Finally, note that the amplitude of the wave—its height—determines its volume. Quite often the amplitude of the waveform changes with time. For example, when you play a piano note, the amplitude builds up to a maximum fairly quickly when you hit the key, but then gradually decreases as the note dies away.

Note also that only repetitive sounds (like a whistle or the note of a guitar) have a definite frequency; other sounds (like the beat of a drum or the crack of a whip) do not.

Sound normally involves frequencies from about 20 to about 20,000 Hz, but many people cannot hear that entire range. Children often hear up to almost 20,000 Hz; as you get older, you hear fewer and fewer high frequencies.

When you reach 60 or 70 years of age, you will be lucky if you can hear up to 10,000 Hz. On the other hand, many animals (such as bats or dogs) can hear much higher frequencies than humans can.

Fig. 7 shows the frequencies produced by each of the white keys of a piano. For example, if you look at the note labeled "Middle C," you will note that its frequency is 261.6 Hz. If you then go an octave to the higher—counting exactly eight notes to the right—you get to the next C, which is at 523.2 Hz, exactly twice the frequency. The piano has about an eight-octave range, and its frequencies range from about 27 Hz on the left or bass end, up to almost 4,200 Hz at the right or treble end. Fig. 7 also shows the frequencies produced by various other instruments. For example, the trumpet produces notes only in the range from about 160 Hz up to about 890 Hz.

That brings up an interesting question: If the frequencies of musical notes range up to about only 4,200 Hz (and most musical instruments have even less of a range), why do hi-fi equipment manufacturers stress that their equipment goes up to 15,000 or even 20,000 Hz? The answer has to do with harmonics.

Harmonics or Overtones

So far, we've explained that

(1) The frequency of a sound determines its pitch or tone, and two instruments playing the same tone will have the same basic frequency. That basic frequency is called the *fundamental.*

(2) The amplitude of the sound determines its volume.

(3) The waveshape of the sound is what gives it its tone quality. For example, a trumpet or violin can play the same note, but they will have totally different waveforms; that is what makes them sound different.

Consider, for example, a square wave like Fig. 8. What is it that makes this wave different from a sine wave?

Suppose this square wave has a frequency of 1,000 Hz. An interesting thing happens when we send it through some tuned bandpass filters—that is, filters that let through only one frequency. This is shown in Fig. 9.

When the 1,000-Hz square wave is sent through a 1,000-Hz filter, out comes a 1,000-Hz sine wave! Nothing comes

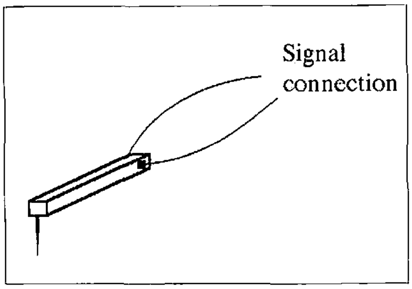

Fig. 2. Simplified crystal phono cartridge.

out of the 2,000-Hz filter, while a small 3,000-Hz sine wave comes out of the 3,000-Hz filter. What's going on!?! (See Detour 2.)

Returning to Fig. 9, we have three filters all looking at the same original 1,000-Hz square wave. We see three things:

• The 1,000-Hz filter outputs a 1,000-Hz sine wave, so there must have been a 1,000-Hz component in the square wave.

• The 2,000-Hz filter outputs nothing; thus, there was no 2,000-Hz component in the square wave.

• The 3,000-Hz filter is also outputting a signal, and we see that it has three times the frequency of the square wave (there are three times as many cycles in the same amount of space); so it seems to be at 3,000 Hz. Moreover, if we were to measure it carefully, we would see that it is exactly one-third the height of the 1,000-Hz sine wave.

If we had more filters, we would see other frequencies as well. Any filter tuned to an odd multiple of 1,000 Hz would show an output, while any other filter would show nothing coming out at all. For example, if we had a filter tuned to 5,000 Hz, out would come a small 5,000-Hz sine wave, and so on.

We can see from this that a 1,000-Hz square wave consists of a large number of components. The 1,000-Hz sine wave is called the *fundamental,* since it has the same frequency as the original square wave. Each of the other components is an exact multiple of the fundamental; the frequency of the 3,000-Hz signal is exactly three times the fundamental frequency, and is therefore called the *third harmonic;* the 5,000-Hz component has a frequency of five times the fundamental, and is therefore called the fifth harmonic. In other words, a square wave consists of a fundamental sine wave signal (whose frequency is the

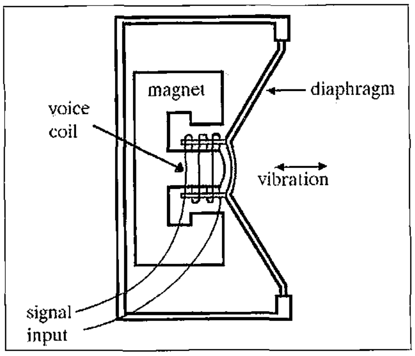

Fig. 3. A telephone-type earphone.

same as that of the square wave), plus a large number (actually an infinite number) of extra frequencies, each of which is an exact odd multiple of the fundamental. We say that the square wave consists of a fundamental plus an infinite number of odd harmonics.

Fig. 10 shows a computer simulation of this situation. It shows a fundamental plus four harmonics (the third and fifth are labeled; the seventh and ninth are not), each of which contributes a little to the output. When they are all added up, we get the wave that looks square shaped, except that its sides don't go straight up and down, and the tops and bottoms are not quite completely flat. The reason it only approximates a square wave is that it has only a limited number of odd harmonics, whereas a perfect square wave requires an infinite number of them.

This is an important concept to understand: The square wave consists of an infinite number of components. Of course, the components have to be just right—they must have the right frequency, the right amplitude, and even the right phase. For the square wave, the rules are fairly simple:

• The harmonics must be exact odd multiples of the fundamental frequency. For example, the 93rd harmonic of a 1,000-Hz fundamental would have to be *exactly* 93,000 Hz.

• Their amplitude must be just right. For example, the third harmonic must be exactly one-third the size of the fundamental; the fifth harmonic must be exactly one-fifth the fundamental's size, and so on, all the way up. Thus the 93rd harmonic would have to be 1/93 the size of the fundamental. This points out that eventually the harmonics get so small that perhaps they can be omitted without making a noticeable difference in the square wave.

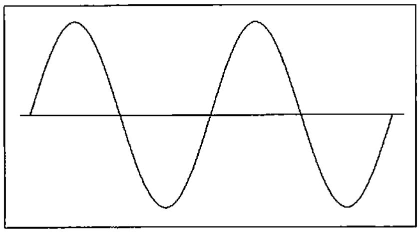

Fig. 4. Waveform of a whistle.

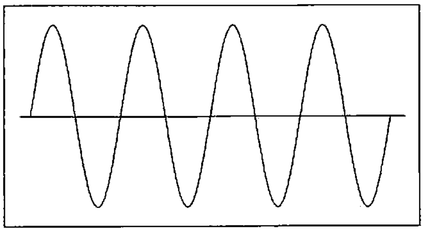

Fig. 5. Whistle waveform an octave higher than that in Fig. 4.

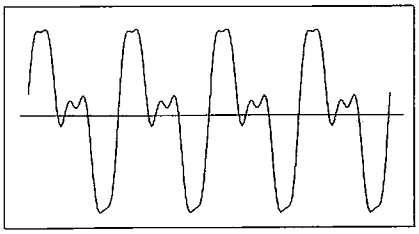

Fig. 6. More complex musical sound.

• Their phase has to be just right. To get the steep rise and fall of the square wave, all of the sine waves making it up have to go up together, and down together, as shown at points *a* and *b* in Fig. 10. If any one of them is out of step, the result will be some wave other than a square wave.

We can extend this concept in two important directions, both of which are critical to understanding many of the circuits in communications:

(1) Just as the square wave consists of a fundamental and harmonics, so *any repetitive waveform consists of a fundamental and harmonics,* although some of these might be missing in special cases. The sine wave is a special case since it has no harmonics at all; the square wave is another, in that only odd harmonics exist, they all rise and fall together, and the harmonics get smaller as their frequency rises. In a more general case, there might be both even and odd harmonics, some harmonics might be large and others small or missing, and they might have all sorts of strange phase relationships. You may have heard of the FFT or Fast Fourier Transform; it is simply a mathematical procedure for finding out what components make up any particular waveform.

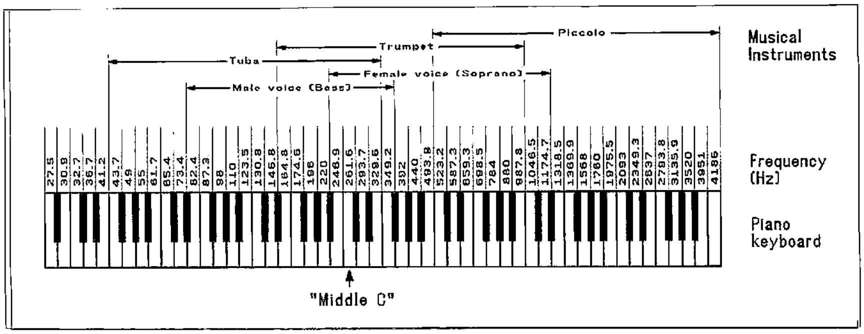

Fig. 7. Frequencies produced by musical instruments.

(2) No matter how you generate that waveform, the harmonics are there even if you don't consciously put them in. For example, one way to generate a square wave is to set up a switch that rapidly switches between a positive and a negative voltage. This setup obviously doesn't put in any sine waves, yet if you look at the square wave with some tuned filters, the fundamental and harmonic sine waves are there.

Let's think about filters again. A filter lets you look for specific frequencies (or colors) in a signal (or in light). But using colored filters to look for specific colors in light is a hit-or-miss proposition if you don't know what to look for; you might need many specific color filters to identify the components in a particular

DETOUR

DETOUR 1

OK, now you see how detours work. Let's detour to talk about transducers. Microphones (also called mikes) come in many different types. Most common is probably the carbon mike, because it is used in every older telephone (the old-fashioned kind, not the newfangled little phones made in the Far East. But not just the real old ones, as in Photo A; more modern ones, too).

Like every microphone, the carbon mike has a diaphragm, which vibrates when hit by a sound wave. The diaphragm in turn moves a thin metal sheet that presses on carbon granules in a small cup. The electrical connection is made to the metal sheet and to the bottom of the cup, as shown in Fig. 1.

The carbon granules are small particles of carbon, which act as a resistance between the cup and the diaphragm. The value of this resistance depends on how closely the granules touch. As the diaphragm vibrates, it alternately squeezes the granules to increase the pressure between them, or releases the pressure. This changes the resistance of the mike in step with the vibrations of the air. The mike is in series with a battery (back in the telephone company's central office, not inside the phone), and thus varies the current in time with the sound. The current variations are converted to voltage variations when the current passes through a resistor or a transformer.

It turns out that a carbon mike has very bad sound quality, but it has one advantage—the voltage variations in the series circuit can be quite large, which means that the electrical signal from the mike can travel long distances without any amplification. This was obviously necessary back in the early days of the telephone, before there were any amplifiers.

Carbon mikes were used in the early days of radio, too, but they were soon replaced by better-sounding mikes.

One inexpensive mike still commonly available is a crystal or ceramic mike. This kind of mike uses a crystal (usually quartz) or ceramic material that is *piezo-electric*. This kind of material is a natural transducer: If you connect a set of terminals to a small block of the crystal or ceramic material, you get a voltage when you squeeze or twist the block; alternatively, the block twists or changes shape if you put an external voltage across it. So it naturally changes mechanical movement into an electrical signal, or vice versa.

Piezo-electric materials have many uses. For example, Fig. 2 shows the idea behind a crystal phonograph cartridge. The needle is attached to a small block of crystal. As the needle rides in the record groove, it twists the crystal, and the two wires attached to the other end generate a voltage proportional to the needle movement. When sufficiently ruggedized, it also works backward. For example, some 40 years ago, Astatic created a recording head that used a crystal to make records. When fed with 50 or 100 volts of audio, the crystal would move a sharp needle and cut a record.

Although crystal cartridges are no longer popular, piezo-electric materials are still often used. One modern application is for lighting a gas flame. When you push a button, a small weight hits a piezo-electric block, which in turn generates several thousand volts. This causes a spark that lights the flame.

In the crystal or ceramic mike, the diaphragm is coupled to the piezo-electric material so that the sound vibrations move the block; this in turn generates an electric voltage that is proportional to the sound signal. The mike can generate a volt or so of audio, though only at a small current.

Crystal and ceramic mikes are somewhat fragile, but back in the days before inexpensive IC amplifiers were available, they were popular because their output didn't need much amplification to be useful. But today's integrated circuits provide lots of cheap gain, so the most popular contemporary mike is the dynamic microphone.

Dynamic mikes work on the same principle as electric generators in power plants or even in your car: When a coil of wire is placed in a changing magnetic field, the coil generates a voltage. This can be done in two ways—either keep the coil stationary and move a nearby magnet, or else keep the magnet stationary and move the coil.

Since the coil is usually lighter and smaller, it's more common to move the coil. In the dynamic mike, the diaphragm is attached to the coil, and the magnet is stationary. When the diaphragm vibrates, the coil moves in relation to the magnet, and thus produces a small voltage.

Dynamic mikes and dynamic earphones have much in common, since the earphone can work as a mike, and the mike can work as an earphone (except that the earphone usually isn't rugged enough to produce much sound). For instance, Fig. 3 shows the earphone from a typical telephone. In this case, an electric current through the coil (which is called the voice coil) produces motion. The *voice coil* is attached to a diaphragm that then vibrates and produces sound. Modern speakers have a similar construction, except that the diaphragm is much larger and is called the *cone*.

As I mentioned above, dynamic mikes and earphones work in both directions. For example, some years ago, after placing a call from a pay phone, I discovered that someone had apparently stolen the mike from the handset. By yelling into the earpiece, I was able to complete my call anyway. But since dynamic mikes (and earphones!) produce much less output than a carbon mike, even with yelling my signal was very hard to hear.

Dynamic mikes can produce very good sound quality, mainly because the mass of the diaphragm and attached coil is very small, and so they easily vibrate in step with the sound wave. Since the vibrations of sound occur very rapidly, a heavy diaphragm cannot move fast enough to accurately reproduce these sound waves. A carbon mike is worse, since it has to move a lot of carbon granules. A crystal or ceramic mike is better, but it still has to apply some force to the piezo-electric material and this increases the mass. A dynamic mike is an even greater improvement because the diaphragm and coil can be very light. The best mike would be one in which there is just a diaphragm, and nothing attached to it at all. There is a form of a dynamic mike, called a *ribbon microphone*, in which the diaphragm is actually a thin strip of foil acting as the coil. But these mikes are very fragile (a strong wind can ruin the foil) and also provide a tiny output, and so they are not very common.

Instead, professional recording studios often use an excellent (though very expensive) mike called a *condenser microphone*. In the condenser mike, the diaphragm acts as one plate of a capacitor. As it moves, the capacitance changes, and an amplifier picks up that change and converts it into a voltage change.

Condenser mikes require a power supply, partially to charge up the capacitor, and partially to power an amplifier right inside the mike. The amplifier is needed because the condenser mike output voltage is tiny, and so it has to be amplified right inside the mike before being sent out the cable. Professional recording studios usually have a 48-volt power supply inside the recording console to supply power to condenser mikes.

The cheap modern version of a condenser mike is the *electret microphone*. These mikes work on the same principle as older condenser mikes, but the diaphragm is made out of a permanently charged semiconductor material that does not need a separate power supply. There is still an amplifier inside the mike, but the amplifier needs only a volt or two to run and so can be powered by a single battery. Electret mikes are not as good as professional condenser mikes (since their diaphragms are heavier), but they are cheap and small. Radio Shack has some electret cartridges for $2; these cartridges are often found inside small cassette recorders. When you buy an actual electret mike, most of its cost is in the case and hardware, since the cartridge inside is often the same $2 cartridge (even cheaper in larger quantities).

light source. You can save a lot of time by looking at the light through a prism, which lets you see all the color components at the same time in the form of a rainbow or *spectrum.* The prism acts like a very large number of filters, all working together to check all the colors at the same time. You can then immediately spot whether a given color is in the light, or whether it is missing.

In communications there is an instrument that does the same job. Rather than looking at a signal through filters that look at just one frequency at a time, we can use a *spectrum analyzer* to break down a signal into its components and display them all on a scope screen as a *spectrum* (notice the similarity to the use of the word in referring to a spectrum of color).

The spectrum analyzer measures the frequency components in a signal and plots the voltage of each component against its frequency. For example, if you were to look at a pure 1,000-Hz sine wave on the analyzer, you'd get a picture like Fig. 11.

If you imagine that 0 Hz is on the left of the screen, and each division to the right represents 1,000 Hz, then the "blip" toward the left would be at 1,000 Hz, and (in this case) have a height of 7 divisions. (Ideally, the blip would be just a thin line, but on the spectrum analyzer it is spread out so it looks like a very tall but thin bell.)

Leaving the analyzer at the same setting, Fig. 12 shows the spectrum of a square wave. This time there is a big blip at 1 kHz (I added small numbers at the bottom of the figure to mark off kHz) indicating the fundamental, and progressively smaller blips at 3 kHz, 5 kHz, 7 kHz, and 9 kHz, showing some harmonics. If you examine Fig. 12 carefully,

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The 73 Flea Market, Barter 'n' Buy, costs you peanuts (almost)--comes to 35 cents a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

The deadline for the March 1996 classified ad section is January 12, 1996.

ALL ABOUT CRYSTAL SETS. Theory and construction of crystal set radios. $9.95 each, ppd USA. Send to: **ALLABOUT BOOKS**, Dept. S, P.O. Box 22366, San Diego CA 92192. BNB200

NEVER SAY DIE

Continued from page 4

CompuServe, Prodigy, bulletin board systems, and so on?

There are almost endless communications services out there. Now, if you, as a bona fide communications expert, can't answer even simple questions about 'em, imagine how confused the average business person is when faced with choices of telephone switches, cellular telephones, teleconferencing, security systems, computer networking, and so on. All this is so far beyond the average person to deal with that you have a tremendous opportunity to make some money—once you know your stuff.

No, you don't know all the answers now, but with your ham background, at least you can understand the questions and you have some clues on where to find the answers. Knowledge is not only power these days, it's money. There are at least ten million small businesses that could be benefited by better communications, security, and computer systems. That's one heck of a market.

How long do you think it would take you to become an expert on pagers, just to pick one field at random? You need to get literature from the manufacturers, dealers, and service companies. You'd want to read a couple books on the subject, subscribe to a magazine. Are we talking six months? One month? A week?

Next you'd want to visit some of the companies involved in the business and talk with them. Find out their problems, what success stories they have, which equipment they think works best, and so on. Couple of months in your spare time?

Now that you have a good understanding of the technology, the players, and have the contacts you need, what should you do next? My recommendation would be to sit down at your computer and write a brief handbook on the subject—maybe 32 pages. Write it for the nontechnical average business person. Explain the benefits this service provides and show how the costs are small compared to the benefits. You can make the handbook look professional by printing it on a laser printer. The first hundred copies can be made on a copy machine. That's the way I do all of my booklets until the demand gets out of hand and practicality forces me to use a commercial print shop.

This will provide you with some sales literature for your new communications consulting service. With your name as the author, this certifies that you are an expert. It's like a Ph.D. Now you're in a position to send letters to local businesses offering the first phase of your communications consulting services.

Once you know your stuff on pagers it's time to pick the next business you're going to learn. If you've made any efforts toward selling your pager expertise, by now you'll know what questions business people are asking about other communications services. You might tackle fax-modems next.

Same deal. Get the literature. Read the books. Subscribe to the magazines in the field. Talk with the manufacturers, dealers, and services. Help some friends for free, learning on their money. It's always best to use other people's money (OPM) as much as possible when you are learning your skills and building your knowledge base.

Within a year, if you make any kind of an effort at all, you'll be Mr. Communications in your town, and you'll have dozens of small businesses turning to you for solutions. In the communications business you make money on sales, on installations, and on service. Great business. All communications equipment breaks, so the service business is wonderful. And computers, being the most complicated of all, break the most often. Plus there are viri, incompatible software, static electricity, errant magnets, and so on, to help keep you living comfortably.

Oh yes, it won't hurt to become an expert on magnetic fields and go around with your gaussmeter and help people avoid possibly harmful fields. There'll be a very inexpensive gaussmeter on the market soon that does a wonderful job.

And when your customers want to know whether cellular telephones are harmful or not, you'll know the answer and be able to give them a reprint of an article from *73* on the subject.

There's no reason for any ham with even the slightest amount of gumption not to be living in comfort and have as big a ham station as he wants. Or she, as a balm to militant feminists. Gumption. Guts. The will to make a change in your daily routine. The will to turn off the TV, to *not* go to that ball game, to *not* read that newspaper. The will to use your time to invest in yourself and a better future.

Expert Help Needed

If you are already an expert on any phase of communications, how about writing an article for possible publication in *73* to help newcomers to the field? They need to know the suppliers, publications, have a list of recommended books, how distribution works, what frequencies and services are available and their average cost—things like that.

If we can get a series of articles to help *73* readers come up to speed on business communications services, that'll help a bunch of hams build some spare-time income, and maybe be able to take their new consulting businesses full time as entrepreneurs. So what's out there in BBS software? In security products and services? In video conferencing? Satellite services?

Or are you happy with your old ham gear and not having enough money to comfortably buy a subscription to *73?* Tsk. The money is out there in great big gobs, you just have to make a little effort to grab it. And that means turning off the ball games and doing some homework instead. Get off the couch, put down that can of beer, brush off the pretzel crumbs, and get cracking. I don't care if you're 20 or 70, you can learn new things and it'll be some of the best fun you've ever had. Heck, I'm 73 now and I'm tackling a whole new branch of physics—one which not even the best scientists in the world understand yet—cold fusion. Now *that's* exciting.

I'd love to know more about communications, so I'll be reading any articles submitted for my own edification and well as yours. That means they've got to be simple enough so I can understand them.

CW Fiends Alert

Just because I am anxious for us to build up our ranks before the FCC wises up and closes us down as no longer relevant, some code-loving readers have misinterpreted this as Wayne hating CW. Well, actually, I really do hate CW, but that has nothing whatever to do with my efforts to get the code test the hell out of the licensing exam system. No, the reason I have always hated the code is because my beloved government made it mandatory.

I have an obviously twisted gene which just naturally rebels against anything mandatory. I wouldn't have lasted long as a slave. Hmm, I wonder if the blacks may have a problem with the natural selection process working over several generations as slaves, thus tending to make them more inclined to be followers than leaders? Sure, call me racist, if that makes you feel superior. But it makes sense, and I haven't ever seen anyone come up with that concept before. And it could help explain a lot of what's been going on.

If the code had been voluntary, I'll bet I'd have been a whiz at it and had a ball. It's always looked like fun, but I'd be damned if I was going to be forced to do something. The Navy and I had some problems with this concept, with them being used to the "How high?" response to a command to jump.

Anyway, for those of you who have had no problem with knuckling under to the government, there's a great little CW magazine you've probably been missing. *Morsum Magnificat* is in its fourth year and is running around 48 pages a month. Subscriptions are $26.50 via airmail from the UK. Make checks out to Wise Owl, 4314 West 238th Street, Torrance CA 90505-4509. Credit cards via 310-375-6258. You'll love the stories and photos of old-time keys.

Once the FCC gets rid of the code tests I'll buy a key and start catching up on the fun I've missed. I might even organize code certificates which can be awarded at hamfests. I started my ineffective campaign to get rid of the code tests in 1958. Will I have made any headway when the 40th anniversary of my windmill tilt arrives? Probably not.

MARS News

Effective October '96, CW will no longer be used on any MARS circuits, according to a recent Department of Defense order. "It is recognized that CW can no longer compete with the rapid advancements in radio technology. Therefore, CW is to be retired from use within the DOD MARS." Newer modes such as packet, AMTOR, and PACTOR have also replaced RTTY.

Digital Camcorder

Digital video has been promised for some time. Well, it's finally arrived, via Panasonic. The camcorder provides 500 lines, which is 50% better than live TV broadcasts. It also records CD-quality audio, and all on a cassette which is 1/12th the size of a VHS cassette. Since the data is digital, it'll be able to connect to computers.

The cassettes use 6.35 mm tape and a 60-minute tape will store 12.5 gigabytes of information. That would take about 8,700 floppies, so this tape should have lots of computer applications for storage and backup. The 60-minute tape is expected to sell for about $14. The camera will be a little more, on the order of $4,000.

Will we someday be seeing ham rigs with a tiny digital camera built in? Only if the hobby doesn't get wiped out by the CW-forever mongers. Hey, would you like to see some video of me swimming with the turtles off the coast of Maui? Or how about the ham gathering on skis on top of Aspen Mountain? Or maybe our ham hunting safari in Africa? Or maybe my visit to the Taj Mahal with a group of Indian hams? Burma? Nepal? Navassa? News at eleven.

Okay, Who's the Quack?

The only ham doctor I can think of right now, the last I heard, is in prison for paying someone to kill his wife. But if there are any ham docs tuned in, I suggest you move on to my next topic and skip reading this. And that goes megadittos for anyone who is a True Believer in our beloved medical establishment. Yes, I've been reading some more books.

My work with a new model of the mind some 40 years ago got me interested in reading up on the various schools of psychiatry, psychoanalysis, and hypnotherapy. Using this model with some hypnotism I found I was able to quickly diagnose and

repair just about any kind of mental problems. And that was something no other approach to mind repair came even close to being able to do.

If you've read much of the literature you know that, in every careful test, none of the mental repair approaches are able to do any better than just giving people tranquilizers. The whole psychiatry business is smoke and mirrors, promoted to a gullible public as reality.

Okay, so I knew the psychologists and psychiatrists were humbugs, but I still had faith in medical doctors. This faith has been shaken recently as I've read more and more about alternatives to the establishment's use of drugs, radiation, and surgery to tackle the symptoms of illness. Doctors aren't even taught how to avoid illness in medical school.

Now I'm reading, *Immunization, The Reality Behind the Myth*, by Walene James, 285p, ISBN 0-89789-360-3. It's a very well researched book and it explains a lot about my own health. And probably, yours. You are so thoroughly inculcated by the media in the reality of vaccinations that you'd better read the book. I know you're not going to believe me when I encapsulate what it says. I really hate finding out that I've been a grade-A sucker all this time.

The bottom line is that not only don't vaccinations do any good, they're doing incalculable harm. The theory itself is baloney, and the billions of dollars doctors and pharmaceutical companies are making is nothing compared to the later costs resulting from the damage done. Yes, I know all about the diseases which mass vaccinations are supposed to have eliminated. So does the author. That's been a huge con job. Read the book

I was a healthy youngster until I had my first vaccination, which was required for me to enter school. Soon afterward I got sinus trouble, and for almost 10 years, and despite nose drops of Neo Silvol or Ephedrine several times a day, I was unable to breathe through my nose, even for minutes. When I was seven I suddenly developed massive allergies, to animals, foods, trees, pollens, dust, and so on. Hay fever, asthma, the works.

These are common results of the destruction to one's natural immunity system caused by vaccinations. Wait until you read the list of problems vaccinations cause! They kill a small percentage of kids outright. Doctors claim this is an acceptable loss, considering all the benefits resulting. Others suffer hyperactivity, autism, attention deficit, dyslexia, multiple sclerosis, cancer, leukemia, arthritis, diabetes, meningitis, tuberculosis, polio, smallpox, chicken pox, obesity, bulimia, thyroid damage, sexual disorders, etc.

Before the smallpox vaccine was discovered, there were almost no cases of smallpox in Japan. Then they instituted compulsory vaccinations. This resulted in 165,000 cases of smallpox, and 30,000 deaths. During the same period in Australia, where they did not have compulsory vaccinations, there were only three deaths. I'm not sure that's really enough to get anyone to think.

And how about cancer specialists in Canada, the US, and Britain who point to a definite link between the polio vaccine and cancer? By the way, the polio vaccine has killed far more children than the disease ever has unassisted by the vaccine. Oh, just read the book and see if it gets you to think.

I'd ascribed the change in family values to Dr. Spock's teaching the baby boomers not to discipline their children. But it could be that childhood vaccinations, plus later booster shots, are the real culprit. They have a tendency to make people more short-tempered and resistant to change. This could help explain our soaring divorce rate and ignored children. "Go watch TV and shut up."

As I've mentioned in my editorials, and in my book of WWII submarine adventures, the doctors came very close to killing me with a tetanus vaccine. It was only my own caution and firm resolve that saved my life. They were really pressuring me to have the shot, and it undoubtedly would have killed me. Thousands of people have died from vaccinations and hundreds of thousand gotten seriously sick.

If you knew that permanent illness or death was a distinct possibility for you or your children, would you voluntarily get those shots? Maybe you remember that last year's Miss America was deaf as a result of a childhood vaccination? Probably not. And I think her sister lost part of her hearing too.

Dr. William Douglass has a new book out claiming that the so-called Gulf War Syndrome is just the reaction to the barrage of shots all our combat troops were given before heading to the Middle East. The soldiers from the European countries did not get these shots and have not reported any of the resulting illnesses. The military does not make any tests before giving the shots, so it's no wonder they have deaths and a wide array of other bad reactions. And once your blood is poisoned by bypassing its defenses against these viruses and germs, you can't ever unpoison it.

There are endless reports of brain damage resulting from vaccinations, but not one report of brain enhancement. Yes, of course they are mandatory and the government will put you in prison if you refuse to have this poison injected into your body, or try to keep your children from being permanently poisoned.

But please don't believe me. Read the book and the overwhelming substantiation of every aspect of this, complete with the truth about all the lies used to force vaccinations on us. They don't work. They have not played any significant part in the reduction of any diseases anywhere in the world. They are a giant multi-billion dollar scam that is doing us all terrible damage.

Hey, maybe you can get your doctor to read the book. He's just as brainwashed about vaccinations as you are, in all probability. But then most dentists are by now aware of the serious damage putting amalgam fillings in your mouth can do to you, but they're still using 'em, and their patients are being slowly poisoned as a result.

Are Darwinians Wrong?

I watched a debate between a Darwinian Evolutionist and a Creationist on PBS the other night. The Creationist not only believed that the Bible's Genesis story is the truth, but that it should be taught in schools instead of the Darwinian theory of evolution: the survival of the fittest. The Scopes trial apparently didn't convince everyone.

The Creationists are upset because the Bible says man is built in the image of God, and the Evolutionists say, in essence, that he's descended from apes. Well, that isn't exactly what they say, but it's close enough. Actually, Evolutionists believe that man and apes are descended from a common ancestor. But one part of the evolution theory that really sticks in the Creationists' craw is the idea that evolution's mutation process is believed to be completely random and not divinely controlled.

It annoys me when scientists go about their business with blinders on. Blinders? Ask the next scientist you meet about ghosts. I have a great deal of trouble totally ignoring the sincere testimony of thousands, and even millions, of people who report things that are currently outside accepted scientific beliefs. Like what? How about ghosts, UFO reports, contactee stories, crop circles, precognition, reincarnation, past lives, near-death experiences, out-of-body experiences, psychokenisis, telepathy, psychometry, psychics, fortune-telling, the power of prayer, angels, poltergeists, voodoo, luck, synchronicity, serendipity, clairvoyance, and so on?

Sure, some of these may be 100% hooey, but where we have thousands of people all around the world reporting the same phenomenon, it's difficult for me to accept that every single one of them is either lying or crazy. Hey guys, maybe it's time to take off the blinders.

Tens of thousands of near-deathers have reported back on their visit to heaven and meeting with God. Isn't it odd that their reports are remarkably similar, no matter what religion they believed in before their experience? And, even odder, when they come back after being told that they have more to do in life, they are usually more religious, but no longer follow the religion they went in with. And they no longer have any fear of death.

They *do* believe in God, but they no longer consider themselves Catholic, Moslem., or any standard brand of Christian, and they're no longer sporting a "Honk if you love Jesus" bumper sticker. I'm not pushing any particular religion, or against any of 'em. I'm just telling you what you'll find if you read some books on the subject.

But that's a side issue which will undoubtedly have the overly-religious furious with me, just as are lawyers when I give facts about them, and ditto most doctors...at least the well-indoctrinated ones. And teachers. No, I don't condemn all of the above, knowing that there are exceptions to the rule. I've met Afro-Americans who don't hate Euro-Americans. I've met intelligent, progressive teachers. I've even met a few honest lawyers, and doctors who are actually open to at least consider alternatives to the usual drug and slash attack on symptoms, and never mind the causes of illness.

That long list of weirdness all comes under the heading of "life" for me. Life is quite separate from matter, though it has to use matter to deal with matter. I'll explain what I think matter is some other time.

Anyway, somewhere lost to history, the first DNA molecule was assembled. This was a molecule which could not only replicate itself endlessly, but also was able to modify itself as a result of the environment and keep that modification in memory. All known life depends on this molecule.

Dr. Fred Hoyle, in his book, *Evolution From Space*, estimated the odds against the DNA molecule being assembled by chance. He compared it to the chance that a tornado sweeping through a junkyard would assemble a complete 747. Well, it does seem odd to some scientists that nature hasn't come up with at least two basic life forms. Hoyle, by the way, is a world-renowned astronomer, so we're not dealing with a science-fiction writer off on a hare-brained crusade.

If you've done much homework in the occult field, you know that as people get in better touch with themselves they develop a feeling of oneness with all life. I've been there, done that, so I know how it feels. I'll tell you about that experience some time. I've put off writing about it because I don't want the Scientologists putting out a contract on me. I wish I was exaggerating.

Say, have you read *The Secret Life of Plants*, which I recommended? Or *Kinship of All Life?* Or *The Secret Life of Your Cells?* Do your homework so when we meet on 20m we'll have something interesting to

talk about...other than the model rig you're using.

Anyway, it seems reasonable to me that life, whatever it is, has a good deal of power to influence matter. We see it in luck, psychokinesis, and so on. So why shouldn't this life force also be able to modify evolution towards its own goals? If the original DNA didn't arrive from space a la Hoyle, perhaps it was the life force which assisted its original assembly?

Of course, if DNA did arrive from space, that just moves back the clock. DNA had to start somewhere, somewhen. And if earth is continually being peppered with DNA-based life forms from space, as Hoyle proposes, it does explain a lot of anomalies. Like why so many diseases suddenly spring up in a number of widely separated areas, all at the same time. And why so many new species have suddenly appeared in history without any apparent evolutionary bridges.

If "life" is influencing evolution, that might to some degree mollify the Creationists. It would certainly make life simpler for Evolutionists, who have a really tough time explaining the rapid evolution of specialized species of animals and plants adapting to new conditions. Shades of Lysenko!

So let's do our best to take off our blinders and be open to information which may not seem to be in line with our inculcated beliefs. The more you learn, the more I think you'll see how things start fitting together. All living things exhibit awareness, even CBers. Where we are different from animals and bugs is in our awareness of our awareness. Our drawback is a tendency to believe our senses. We believe what we see, so when some joker comes along and tries to convince us our senses are wrong, we kill him. Everyone can plainly see that the sun is going around the earth. And the stars, too. And the earth sure looks flat to me.

It comes as a shock to some when people find out that over 12,000 years ago astronomers worked out the circumference of the earth to within a 163 miles (they didn't allow quite enough for the bulge at the equator). And they even knew that the earth wobbled on its axis with a period of 26,000 years.

Copernicus and Galileo did not have an easy time convincing the scientists of their day that their beliefs and senses were wrong. So what's changed? The mental trip from believing that the earth was the center of all creation to understanding that it is a small planet in a relatively new solar system, out toward the edge of one of billions of solar systems in our galaxy...and that our galaxy is just one of billions of other galaxies, is a terrible downer. And where does God fit in this mind-bogglingly enormous universe? If you have an NDE and think to ask The Big Guy, please let me know when you get back.

Vanity Calls

The FCC is gradually phasing in vanity callsigns. They'll cost you $30 for a 10-year license. Cheap enough. When they get started, the FCC will be accepting applications (form 610-V) for the reissuance of calls you may have had in the past and lost, or the call of a deceased close relative. Hmm. I wonder if I should apply for W4NSD or W8NSD, or perhaps WR1AAB? Or K2PMM? I've had a bunch of calls down through the years, but I guess I'm stuck with W2NSD/1 until the Commission eases their restrictions so I can get "W."

Phase two will be open to Extra Class licensees. Then Advanced Class. And when that's all taken care of, any licensee will be able to invest $30 to get rid of KF4ZXZ, or some other awful combo.

The Candy Company used to issue the same suffix in a new area when you moved. That's how I got W4NSD, when I moved to North Carolina. And W8NSD, when I moved to Cleveland to work at WXEL-TV. By the time I moved to New Hampshire in 1962, the CC had stopped this generosity, so even though W1NSD was open and available, they wouldn't let me have it. They said they expected the rules to be changed soon, so just to operate portable and hold my water. I'm still holding 33 years later. I probably don't have the record for operating portable, but I'm right up there.

It's probably been months since I've told you about my operating in the Sweepstakes contest from Ohio in 1951 as W2NSD/8. Then, just as my W8NSD license came through, I moved back to New York, so I operated the second weekend of the contest as W8NSD/2. The only common piece of equipment was the microphone. Even so, I did well in the contest.

Someone else has been issued my 1958 license for Navassa, KC4AF, so I won't be able to get that one back. Drat!

The address for the vanity calls, once the FCC gets their computer programmed, is: FCC, Amateur Vanity, Box 358924, Pittsburgh PA 15251-5924.

Alchemy Today

If you know anything about chemistry at all you know that you can't turn lead into gold. Well, it seems that the old alchemists were a little further along than history has been leading us to believe. It wasn't lead, it was mercury that they were transmuting into gold, and the "philosopher's stone" they used to help the action was made of phosphorous. I know you're going to find this difficult to believe, but the Japanese have been doing a good bit of research on this more recently, and with considerable success.

My interest in the transmutation of elements began when I read the Bird-Tompkins 1976 book, *The Secret Life of Plants*. There was a chapter on how chickens are able to convert the potassium in mica into calcium for their eggshells. It almost got me to think. So I chased down Christopher Bird and got up to date on some of his newer books. His *Secrets of the Soil* is fantastic. It's a must read. I also got in touch with Cleve Backster, the chap who did much of the original work on communicating with plants. And he put me on to Brian O'Leary and *The Secret Life of Your Cells*, another fascinating book. But I've told you about those and you should have read 'em by now.

Chris suggested I look up the transmutation work by Michio Kushi. I found him and think you ought to know about his 1994 book, *The Philosopher's Stone*. Before you dismiss transmutation via biological processes as baloney you should at least look at the remarkable research data Kushi presents. He makes a very good case for the heavier elements on earth being made biologically from carbon, oxygen, and nitrogen instead of having to have originated from a supernova explosion, which is the current scientific dogma. It turns out that many scientists have researched this area with very positive results.

For instance, take $_{11}Na^{23} + {}_{8}O^{16} \rightarrow {}_{19}K^{39}$, for starters. Kushi put 2.3 mg of sodium in a vacuum, then ran an electric current through it until it was melted. Then he added 1.6 mg of oxygen. The result was 3.9 mg of potassium.

Then there is the data from Louis Kervran, who carefully checked the input and output of food and wastes from a group of men working in the Sahara in 1958. They generated far more magnesium output than input. Ditto potassium. More than could be accounted for in any way other than biological transmutation.

I think you'll enjoy the book, and it may almost get you to think. Or not. It's $10 (plus s/h) from One Peaceful World Press, Box 7 Becket MA 01223, ISBN 1-882984-07-2; 413-623-5741.

One of the reasons I got interested in transmutation is that the scientific establishment has been putting cold fusion down because it seems to involve the changing of hydrogen into helium, and "everybody knows" that alchemy died a deserved death a couple centuries ago.

Those Pesky ETs

Somehow, in amongst trying to keep up with the editing and production deadlines for two magazines a month (*73* and *Cold Fusion*), I also manage to read my mail and even answer some of it. For instance, I got a wonderfully chatty letter from Frank Thomas W4QDM. It didn't hurt when he started off saying how much he likes my editorials and the challenges I provide. He's been reading many of the books I've recommended and enjoying them.

Sure, I could just write about amateur radio, but my editorials are more like a monthly contact with you, where I talk not just about the hobby, but about anything else I think you might find interesting. And that's what you like about some of the ham contacts you make, isn't it? So get off the concept of everything printed being a lecture and get the idea of communication.

Anyway, Frank mentions that he's interviewed two people from Sylvania (GA) who had good close looks at a UFO which had landed in a field near town. One was a retired meteorologist from the Dept. of Commerce, and the other was the owner of radio station WSYL, so their credibility was high.

Unless you've been living in a cave with no radio or TV, you've seen and heard plenty of UFO stories. I've got stacks of UFO books—some are kooky, but many are well researched. The author of one was a good friend of mine, Jay Stanton. I've forgotten his ham call. When I first moved to New Hampshire he used to come up and visit. He went into the UFO book project as a skeptic, with the intent of exposing the whole business as baloney. He soon was convinced that most of the reports were real. Millions of people have seen UFOs and they're not all crazy. Thousands have reported being abducted, many repeatedly.

Another reader sent me a most interesting tape of David Jacobs talking about the real purpose behind the abductions. More *National Enquirer* stuff, right? Only if you don't do your homework. It's easy to dismiss something you don't know much about. Look at the fools some top scientists recently made of themselves in dismissing cold fusion. And we had the spectacle of the medical establishment trying for years to deny *H. pylori* as the cause of ulcers. And the ongoing power company fight against EMF dangers, the tobacco companies and cancer, and the ADA's fight to continue the use of dental amalgams despite all the scientific evidence of their destructiveness.

With the Big Bang theory now having been pretty well discredited, scientists admit they haven't any clue as to the age of the universe. This tends to make the possibility of there being alien visitors from more advanced civilizations much more likely. And then there's the possibility of time travel to further confuse things. We've enough reports of verified precognition to know that we still have a lot to learn about how time works.

I'll keep letting you know about the books I've found which I think you'll enjoy. When you come across a book you think I should read, please let me know.

Continued from page 71

you will see that the blip at 3 kHz is one-third the height of the fundamental at 1 kHz, and so on.

The presence of harmonics has an important effect on communications. Whenever we talk about sending a signal from one place to another, we have to make sure that all the components of that signal (or, at the very least, the *important* ones) get through as well. This brings us to the concept of bandwidth.

Bandwidth

Consider piano music. Obviously having a phonograph that covers the range from 27 Hz to about 4,200 Hz will let through all the notes, allowing us to recognize the melody.

But a restricted range like that does not sound like a very good piano. To make it sound realistic, you must let through all the harmonics—or at least the ones you can hear. That is why modern hi-fi equipment typically reproduces up to 20,000 Hz (or, at least, that's what

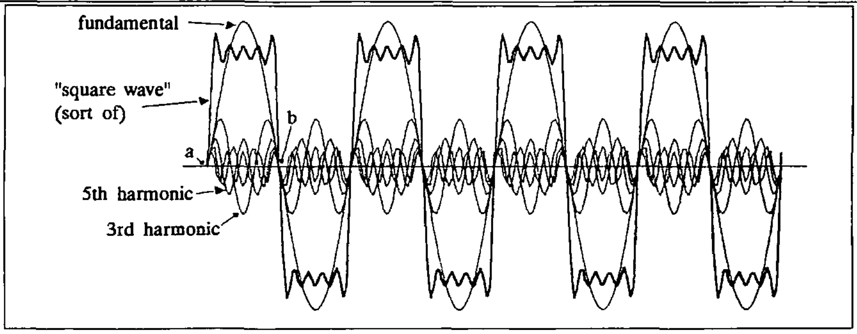

Fig. 10. Making a square wave out of a sine wave.

DETOUR

Detour 2

Let's talk about filters for a moment. Suppose you get several pieces of colored glass—one red, one green, one blue. When you look at a light bulb through the red glass, you see red light. Look through the green glass, and you see green light; look through the blue glass and you see blue light.

Don't think of the colored glass as a filter that is changing the white light into colored light. Instead, remember that white light consists of many colors, all combined together. The colored glass is simply a filter letting one color through, while stopping all the other colors. We can demonstrate that easily be putting the green and red glasses together and trying to look through both of them. When the white light goes through the red glass, only red light comes out. There is no green light left, and so when that red light hits the green filter, it is all stopped and nothing comes out (assuming that the filters are good enough).

If we have light from some unknown source, colored glass filters let us test that light to see what colors are in it. If we use a particular color glass, and nothing comes through it, then we know that that particular color was not generated by the unknown light source. But we can also interpret this result in a different way: if what comes out of the glass filter is different from what went in, then the original light must have had some colors in it that did not pass through the glass.

In the same way, electronic filters, like those in Figure 9, let us test an electrical signal to see what its components are. When we put a 1,000-Hz square wave into a 1,000-Hz filter, but a sine wave comes out, this tells us that the original square wave must have some other frequencies in it that cannot get through the filter.

the manufacturers claim!) In fact, 15,000 or even 10,000 Hz would probably do for us older people whose hearing no longer extends to 20,000 Hz (pity!)

Let's look at the frequency ranges covered by various pieces of equipment:

- •SSB transceiver—about 300–2,700 Hz.
- •Telephone line—about 300–3,500 Hz.
- •AM broadcast station—about 100–10,000 Hz.
- •FM broadcast station—about 50–15,000 Hz.
- • Compact disk—about 5–20,000 Hz.

Looking at these frequency ranges, we can clearly see which equipment will handle music best, and which is merely good enough for voice. (See Detour 3.)

So far, we've taken a short look at the nature of audio. We have seen that audio signals consist of frequencies in the range of about 20 Hz to about 20,000 Hz, but that a narrower bandwidth suffices if we're not too concerned with quality. For example, a typical telephone circuit can handle only the range of about 300 Hz to about 3,500 Hz.

A frequency range up to 3,000 Hz or 4,000 Hz is good enough to understand speech and even to recognize the voice of the speaker, but it is certainly not hi-fi. Let us now look where time comes into this.

Time

Say you have 20 minutes of things to tell him. You decide to record it on tape at a low speed. Then you rewind the tape and play it back, but at double the speed so that it takes only 10 minutes to play. Can you thus send 20 minutes of speech, but pay for only a 10-minute phone call?

You can certainly do that, but your voice will sound like the Chipmunks (that's how they do their voices!) and may not be too understandable. But suppose your friend records your voice on another tape recorder, but this time records at high speed and plays it back later at half-speed (try this with a Chipmunks record!) This stretches the 10 minute tape back into 20 minutes. Will this work? (And if it does, can you speed up the tape by a factor of 10 and pay for only a 2-minute call?)

Yes . . . and no. What happens is that as you double the speed of your tape, every frequency on the tape gets doubled too. A 1,000-Hz component of your voice becomes 2,000 Hz, and so on. The problem is that every component of your voice that is above 1,750 Hz or so gets doubled to above 3,500 Hz, and therefore doesn't make it through the phone line. In other words, your friend will only hear those components in your voice that are below 1,750 Hz. (And if you tried to speed things up by a factor of 10, he would only hear those parts of your voice that are below 350 Hz.)

In other words, it's the bandwidth of the telephone line that limits how much information you can get across in 10 minutes. If you used a higher-bandwidth line—such as the special lines that broadcast stations lease from the phone company for studio-to-transmitter links, which cover up to 10,000 or 15,000 Hz—you could easily speed up your tape by a factor of 3 or 5, and still transmit all of your message (though still only at normal telephone-line quality).

So the idea is that there is a tradeoff between bandwidth and time. If you have a fixed amount of information to send, you can send it fast if you have a lot of bandwidth. But you have to send it more slowly if the bandwidth is small. That explains why, for example, a fax transmission can go through a regular telephone line, but a full-motion TV video image can't. The fax takes up to a minute to send one picture, whereas the TV has to send it in 1/30 of a second.

Summary

Although the discussion has rambled off and on about various aspects of audio, we've actually covered a lot of ground. We have seen the characteristics that make up an audio wave—the frequency, wave shape, and amplitude of the signal. We have looked at how harmonics affect the wave shape, and how the bandwidth of a system affects the sound quality that you can send through it. Next time we will tackle transmission of video.

DETOUR

Detour 3

While we're on the subject of hi-fi equipment, let's discuss a few more terms.

It's not enough for a piece of hi-fi equipment to cover a wide range of frequencies; different frequencies in the range have to be treated equally. That is, an amplifier or tape deck that covers 20–20,000 Hz, but provides a lot less gain above, say, 1,000 Hz than below, would sound very bassy. Ideally, hi-fi equipment should be able to handle signals of different frequencies equally well. Evenness of response is usually rated in *decibels* or dB. For example, a typical amplifier might have a rating of "20–20,000 Hz ±1 dB," which means that the gain (how much it amplifies) does not vary more than plus or minus 1 decibel from some midscale value. (We'll have a detour later to explain decibels.)

In addition to having a wide frequency range, the hi-fi device also should not distort the signal. That is, its output waveform should look like the input waveform (except for possibly being larger or smaller). One way to rate distortion is as THD or *total harmonic distortion*. Remember that it's the harmonics that make one signal of a given frequency different from another signal of the same frequency. Hence if the output from an amplifier or recorder looks different from the input, its harmonics must somehow have been changed. The standard way of measuring this is to insert a pure sine wave test signal (that has no harmonics), and look to see whether there are any harmonics in the output. If so, then the signal got distorted. The THD number is a percentage that tells how much harmonic voltage got added to the pure signal. For instance, if the output from an amplifier (with a sine wave input that should have no harmonics) is 10 volts of fundamental and 2 volts of harmonics, then there would be 20% THD (a terribly high number, by the way. THD values of under one or two percent are more desirable).

Actually, though, harmonic distortion is not nearly as bad as you think. Since music and speech normally have harmonics anyway, adding an extra percent or so of harmonics to them is not too noticeable. Amplifiers and other all-electronic hi-fi equipment tend to have low distortion, but tape recorders and mechanical components such as phonograph cartridges and speakers often have a high THD (sometimes as much as 5% to 10% for speakers).

Much more dangerous is IM or *intermodulation distortion*, which introduces new frequencies not in the original at all. Even 1/2% or 1/4% IM distortion is grating and unpleasant. Unfortunately, IM distortion is not very often listed in spec sheets for equipment; fortunately, however, IM distortion sort of goes hand in hand with THD, and a hi-fi device with low THD *probably* also has low IM.

Finally, hi-fi equipment should have very little noise. Noise can appear in the form of a low-pitched hum (often caused by a bad power supply, bad grounding, or bad shielding of a wire) and a high-frequency hiss. Either one is bad. Hi-fi equipment specs therefore often list the SNR or *signal-to-noise ratio*. This is the ratio between the loudest music it can handle and the noise. For example, in a CD recording, the loudest music voltage is typically about 65,000 times higher than the noise voltage, while in a cassette recording it might only be 300 or 400 times stronger. In a telephone circuit, the ratio between the loudest voice signal and the noise might be as low as 10 to 1. Since we're holding off on our discussion of decibels, let me just say at this point that the 65,000 ratio is equivalent to about 95 dB, the ratio of 300 to 400 is about 50 dB, and a ratio of 10 is only about 20 dB.

SPECIAL EVENTS

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the May issue, we should receive it by February 29. Provide a clear, concise summary of the essential details about your Special Event.

JAN 13

HARRISBURG, PA The Harrisburg RAC will hold a Hamfest 8 AM-Noon at Oberlin FC Social Hall. For info. call (717) 232-6087; for table reservations, write *Tom Hall WU3X, Box 418 Halifax PA17032*. Talk-in on 146.76 and 146.52.

LOVELAND, CO The Northern Colorado ARC will sponsor the Winter Superfest at the Larimer County Fairgrounds, 700 S. Railroad. Talk-in on 144.515/.115 Pl 100 Hz; or 146.25/.85. VE Exams, tables, contact *Jeanene Gage N0YHY, (970) 351-7327. For general info, call Michael Robinson AA0UB, (970) 282-1167.*

PHOENIX, AZ The ARC of Arizona, hosted by ThunderBird ARC, will hold the West Valley Hamfest (WestFesT) at Glendale Comm. College, North lot, 6000 W. Olive (Dunlap & 59th Ave.). Contact *Morgan N7DLW, (602) 938-4356.* or *Mark N7KKQ, (602) 843-0960.*

JAN 13-14

SARASOTA, FL The Sarasota Hamfest and Computer Show will be held 9 AM-5 PM Sat.; 9 AM-3PM Sun. at the Robarts Sports Arena, Sarasota Fairgrounds, 3000 Ringling Blvd. Contact *Sam Everts KE4BXF, (941) 927-8999.* Talk-in will begin at 8 AM each day on 146.31/.91 and 444.925/449.925 Rptrs.

JAN 14

DOVER, OH The Tusco ARC Hamfest will be held at Ohio Nat'l. Guard Armory, 2800 No. Wooster Ave., starting at 8 AM. Setup at 6 AM. Contact *Howard Blind KD8KF, 6288 Echo Lake Rd. N.E., New Philadelphia OH 44663. Tel. (216) 364-5258.* Talk-in on 146.730(-).

JAN 20

GOWER, MO The 6th Annual Northwest Missouri Winter Hamfest will be held 9 AM-4 PM at the Ramada Inn in St. Joseph MO. Sponsors: Missouri Valley ARC, Green-Hills ARC, and Ray-Clay ARC. Commercial exhibitors welcome. Contact *Northwest Missouri Winter Hamfest, c/o Gaylen Pearson WB0W, 121- Midyett Rd., St. Joseph MO 64506.*

JAN 21

YONKERS, NY The Metro 70cm. Network will present a Giant Electronic Flea Market 9 AM-3 PM at Lincoln H.S. VE Exams. Indoor Flea Market. For registration, call *Otto Supliski WB2SLQ, (914) 969-1053.* Talk-in on 449.425 MHz Pl 156.7; 223.760 MHz Pl 67.0; 146.910 Hz; and 443.350 MHz Pl 156.7.

FEB 3

KNOXVILLE, TN The Shriners of Kerbela AR Service will sponsor the Kerbela Hamfest at the Kerbela Shrine Temple, 8 AM-4 PM. Setup Fri. 4 PM-9 PM; Sat. 5 AM-8 AM. FCC Exams by WCARS-VEC. Reg. until 9:30 AM. Mail completed 610 form with check for $6.05 payable to *WCARS-VEC, Ray Adams N4BAQ, 5833 Clinton Hwy., Suite 203, Knoxville TN 37912-2500. Tel. (423) 688-7771.*

ST. CATHERINES, ONT., CANADA The Niagara Peninsula ARC Big Event #18 will be held at the Canadian Auto Workers Hall, 124 Bunting Rd., 9 AM-2 PM. Setup at 7 AM. Contact *Marg Sewell VE3HOX, NPARC, P.O. Box 20036, Grantham Postal Outlet, St. Catharines ON L2M 7W7. Tel. (905) 680-1211.*

FEB 3-4

MIAMI, FL The 36th Annual Tropical Hamboree Amateur Radio and Computer Show will be held at Dade County Youth Fair and Expo Center, S.W. 112 Ave. & Coray Way. Sponsored by Dade Radio Club of Miami. Talk-in on 146.925. Booth and table info: call *(305) 642-4139;* or Fax *(305) 642-1648.*

SPECIAL EVENT STATIONS

JAN 20

SANDUSKY, OH The Sandusky Radio Experimental League will operate W8LBZ 1500Z-2400Z to celebrate the 100th Anniversary of the "Boy with the Boot" statue, Sandusky's official symbol. Operation will be in the General 40, 20, 15m bands, 146.655(-), and 444.375(+) Rptrs. For a certificate, send an SASE to *W8LBZ/SREL, 2909 W. Perkins Ave., Sandusky OH 44870.*

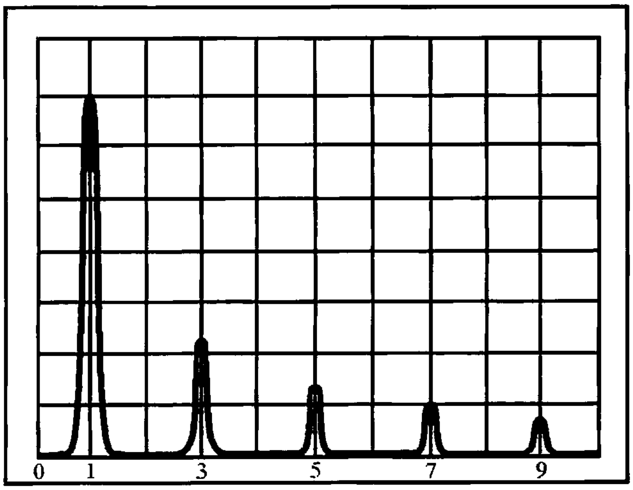

Fig. 12. Spectrum of a 1,000-Hz square wave.

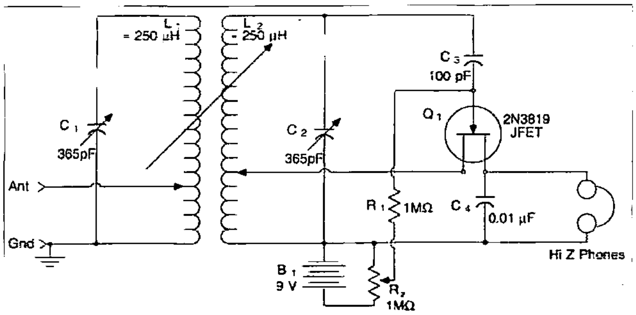
UPDATES

In December's *73*, we ran David W. Cripes KC3ZQ's article, "Nostalgia for the Future," without the all-important schematic. Here it is:



The Ultimate Crystal Receiver

Letters
Continued from page 6

my license. In 1987, I re-tested and quickly acquired my General License again. Late in 1994, I passed the Advanced Class upgrade, and in August 1995 I upgraded to Extra Class. I have had to renew my high school memory of trigonometry, as well as learn how to use a scientific calculator. My main talent is sewing, not electronics, but I passed the test, three months short of being eligible for Medicare. And I understand that keeping the mind active wards off Alzheimer's disease and other maladies. I am very appreciative of the ham community, which has kept the bands active throughout the years in order that those of us who have been less active still have frequencies on which to operate. That means the old-timers. They probably have more stick-to-it-iveness than some of the newcomers. If they have not become bitter through the years, they have more manners than some of the younger generation. And manners speak well for amateur radio. And, off of that subject: May I suggest/request that it would be easier to respond to "Feedback" if the back side of the listing were an ad, rather than an article or printed circuit diagram?

Noted . . . Wayne

Jack Conway N5YIS I never go to hamfests, so I thought that I would never have an opportunity to hear you speak. When I read in *73* that you had a tape for sale, I just had to have one. Here is my five bucks: After reading years of good money-making ideas from you I thought I would send you two that you can have free of charge. Your offer to sell back issues of *73* was tempting, but like most people I don't have room for any more magazines. I do, however, have room for more CD-ROMs, so why don't you scan all your back issues onto CD ROM's and sell them? I know I would buy them just to read all the editorials. Why don't you put your audio publishing house to work putting together a Morse code CD? Reading the different magazine I read, I have always wondered why nobody put together a Morse code trainer on CD. Most CD players have a random play feature. I think it would be the best medium for practicing code. Keep cranking out the quality editorials.

Sure, I'll bet I could sell dozens of CD-ROMs of the back issues. Let me know if you'd like to scan in the 50,000 pages for me. Or maybe I could get some retired ham to scan in my over 1,000 editorials. I'll bet I could sell scores of those on a CD-ROM. We did a CD-ROM listing of every known CD back in 1989 and sold dozens of 'em. We even scanned in the color covers for hundreds of 'em, and had sample tracks of the music. It sold like cold cakes. The code? All it takes is one one-hour tape at 13 per to learn the code from scratch. And one at 20 wpm for that speed. Why would anyone put an hour of code on a CD when a tape does it just fine? . . . Wayne

Dave Kaun N9KMY It is truly time for our hobby to move into the new technology age. We need to substitute application of technical skills for Q&A manual memorization and the copying of the code as a method of advancement. Memorization, popular as a teaching method in previous generations, is no longer the way learning takes place today. While we expect our youngsters to understand and apply huge amounts of technical information, why are we still requiring memorization in amateur radio? Let's make our hobby a natural learning progression for technically literate students interested in what ham radio offers.

After many years of being involved with electronics as a hobby and as my career, I became a Technician before the no-code license was offered. To me the technical side of the hobby is much more important, though I would enjoy working HF if it were not for the artificial barrier the code presents. I find it quite interesting that many who once long ago learned the code can't carry their side of a technical conversation equal to the license they hold, nor even remember the code well enough to use it. More than memorization is needed today to understand technology: just ask any engineering student if formula or fact memorization is enough. Learning and understanding applications is much more important. We need to follow that same methodology of learning in amateur radio. Keep up the good work and the excellent magazine.

Philip Weaver VS6CT Wayne, it's been awhile since our paths crossed. I am leaving for the CRSA DX Convention in Beijing later today and was remembering how we met in the BY1PK Radio shack in Beijing back in 1984, when I was assisting with the communications associated with the Hong Kong-to-Beijing "555" Car Rally. I retired from the Hong Kong Government in February of this year and I have not stopped since. I will be dashing around Asia for the next two months, with visits to Bali, Thailand, Hainan Island on the South Coast of China, and Kota Kinabalu. I sold my flat here in Hong Kong and will be leaving for England in December to join the QE2 out of Southampton for a four-month round-the-world cruise. I am hoping that I will have managed to organize the setting up of a ham station on board and am awaiting word from Chip Margelli of Yaesu to supply me with a radio as the official sponsor of the station. I'll return to England in mid-April and expect to be back out here in Hong Kong in late May to try to find a flat where I can put some decent antennas on the roof. I am very bullish and optimistic about the future of Hong Kong, which is why I want to stay here, apart from the advantages of being somewhere that I know. I've enjoyed living here for 22 years. I just hope that my faith will be justified in the future. I still read your editorials with enjoyment, I just wish that they could produce more results. Keep at it Wayne.

Phil, I hope your trust of Beijing not ruining Hong Kong is justified. It's too bad the changeover isn't in 10 more years, after China has had an opportunity to adjust to capitalism . . . Wayne

Free Electricity
Continued from page 34

conditioning and refrigeration. A superefficient Sun Frost refrigerator will replace the old conventional unit when it dies. The Sun Frost unit retails for about $2,700. A 16-cubic-foot Sun Frost uses 32 amp/hrs. a day at 24 volts. That's about one tenth the amount of power the old refrigerator uses.

Chuck also has a landline BBS operating 24 hours a day with an Amiga computer as the heart of the system. He can save a lot of energy by converting to a laptop computer.

As I mentioned earlier, when the wires were being pulled through the underground conduit, several multi-conductor cables were also installed. These data lines will eventually be used to monitor system parameters such as array temperature, wind speed and direction.

Are there any 12-volt DC loads? Yes, and a Vanner battery equalizer allows a 12-volt battery bank to be charged from the main 24-volt battery bank.

Author's Note

I'll be happy to do a computer sizing for your repeater or hamshack. There's no charge for this, provided you send along several first class stamps for return postage. I'll need your name and the nearest large city with an airport having a weather station operated by the US government. I'll also need the system voltage of your load (12, 24, 48 volts), and an estimate of the amp/hr load you expect.

Two meter SSB/Satellite Loops

A whole new world of fun lurks on the low end of 2M if you use the right antenna.

Gordon West WB6NOA
2414 College Drive
Costa Mesa CA 92626

The bottom end of the 2 meter band below 144.300 MHz is reserved exclusively for weak signal SSB and CW communications. No FM. Same thing between 145.800 MHz to 146.000 MHz—*no FM!* This area is reserved for weak signal satellite communications using SSB and CW. The term "weak signal" describes running 2 meter CW or single-sideband signals over great distances, well beyond normal FM 100-mile communication ranges. Weak signal modes like Morse Code (CW) and SSB (upper sideband) *cannot* coexist with FM transmissions because a nearby FM signal will literally cover up an ongoing SSB or CW QSO. So keep in mind that no FM is allowed below 144.300, and no FM between 145.800 to 146.000 MHz. Thanks for your cooperation!

Down below 144.300 MHz is where SSB communications span distances well beyond 100 miles. It's not uncommon for atmospheric tropospheric ducting to carry 2 meter SSB signals over thousands of miles, such as the path that occurred last summer between Nova Scotia and Florida. Last summer also saw the 2 meter SSB records shattered for the ultimate distance contact between Washington and Hawaii. The conditions lasted for several days!

Almost all communications on 2 meter SSB below 144.300 MHz use horizontal polarization, rather than vertical polarization. If you spot a beam antenna on a house that is mounted horizontal for 2 meters, chances are they're operating a 2 meter multi-mode SSB system. If you see a horizontally polarized antenna or a combination vertical and horizontal Yagi antenna pointed up toward the sky, this is probably a satellite set-up for 2 meter work. But there is probably one horizontal antenna that will really make you take a second look, and it is the 2 meter horizontal *loop* antenna.

"How about that 2m SSBNova Scotia to Florida contact last summer?"

This is what mobile units must use in order to obtain coverage, yet with a horizontal 2 meter pattern. The new popular ICOM 706 with 2 meter and 6 meter VHF capabilities in addition to high frequency capabilities will lead mobile operators over to a 2 meter horizontal antenna for work below 144.300 MHz.

A popular compact 2 meter square loop, called the "SQUOOP" is offered by M² Enterprises, Fresno, California (209-432-8873). The little 2 meter "SQUOOP" is housed within a black plastic cover, and offers unity gain omnidirectional coverage in an aerodynamic design that works well on any vehicle or mobile home as long as you get it well above the roof line. I have tested it against other loops, and its performance is O.K.

If size is not the object, consider the big cloverleaf horizontal loop that is a little bit more at home on your roof than on the roof of your vehicle. It's big, but all that metal really captures weak incoming horizontally polarized 2 meter waves. It's available from Laddy Reisinger N8EWU in Oceanside, California (619-722-8563. I found its performance slightly above the M² little loop, since all that metal captures a little more of the incoming horizontal signal.

Another Southern California ham, Norm Pedersen KB6KQ, Bellflower, California (310-925-0733)), has developed a "Mini Loop" that has a high performance for its small size and is easily stacked for a slight increase in weak signal capture capabilities. We recently tuned in Paul Lieb KH6HME, driving up the side of a volcano in Hawaii using a single Mini Loop, and his signal was making the 2,500-mile path extremely well. For the smallest loop with the greatest signal capture capabilities, this loop has it hands down. It's also a home-brew antenna offered to amateur operators on 2 meter SSB.

Another attention grabber is from the M² gang, a Mike Staal K6MYC special, Fresno, California (209-432-8873) is called the "Egg Beater." This can be used for both 2 meter horizontal SSB communications with terrific signal-grabbing capabilities, as well as right hand circular polarized mobile satellite work up at 145.800, too. The Egg Beater had best response to the Hawaiian 2 meter beacon when it was coming in just above the noise level. The Egg Beater did best, with the Mini Loop coming in a very close second, followed closely by the cloverleaf, followed relatively closely by the M² "SQUOOP." All of these antennas look out of place on a modern vehicle, but hey, that's the price to pay when you want to work 2 meter mobile SSB and regularly talk to other mobiles over distances beyond 100 miles. And we are not talking through repeaters, we are talking direct. The advantage of SSB simplex over FM simplex is double, triple, and sometimes quadruple greater on SSB than what you could do with wide and noisy FM.

I've also found many newcomers getting started with 2 meter SSB wanting something nice and compact. The gang at Cubex Quad Company rose to the challenge of a compact pre-assembled quad specifically tuned for the 2 meter band and operated either vertical for FM

or horizontal for 2 meter SSB. Cubex Company in Brea, California (714-577-9009) calls their little 4-element, pre-assembled, lightweight cubical quad the "Yellow Jacket," and everything comes pre-assembled where all you need to do is to poke the supplied fiberglass spreaders in through the holes on the boom, attach the pre-assembled and color-coded wire elements around the spreaders, run your coax, and sand off the ends of the spreader wire tips so they are nice and smooth in case someone should walk into your assembled quad antenna set-up. You know, safety first! The quad sells retail for under $40, and gives you a big boost in directional signal strength well above a simple ground plane home antenna or equal gain to a little 3-element Yagi. The quad also comes with its own mast and could serve as a wonderful direction-finding antenna, too. Everything is pre-assembled, so you don't have to do any measuring or anything—just follow the instructions, snap everything together, and presto, you are on the air with either vertical or horizontal polarization. For 2 meter SSB and CW, make sure you go horizontal and point the quad for best signal strength.

During extensive testing of omnidirectional mobile loops, all did a terrific job in pulling in extremely weak SSB signals, including the Hawaiian beacon thousands of miles away. But switching over to the quad and aiming it in the right direction definitely increased transmit and receive signal strength. Same thing in working the satellite.

You can also build these horizontal antennas yourself, like the gang in California has done for resale. But I recommend getting one already put together, tuned, and tested rather than trying to outdo what somebody has already spent years in design and testing. Learn from their hard work what it takes to make a good horizontal antenna even better through refinements. See whether or not bigger is always better, and check out some of the tuning techniques these experts have used to give you proper impedance matching and performance right where you need it on the weak signal portion of the bottom of the 2 meter band.

RF Sniffer

Here's an ultra-simple piece of test equipment

J. Frank Brumbaugh KB4ZGC
Box 30
Salinas PR 00751

An old trick for sniffing out RF leaking around the shack can be useful in modern ham station installations. Any RF which does not reach the antenna is not only wasted power, it often can be the source of interference to radios, TV sets, telephones and other home electronics. The opposite is also true - if RF can get out, it can also get in - and RF from motors as well as household electrical and electronic equipment such as TV receivers, VCRs, etc. can raise the noise level in the ham receiver and otherwise interfere with station operation.

Old, surplus coaxial cable and some new coax is so poorly shielded it is little better than open wires. Coax which leaks RF should be replaced with high quality cable. Poor, leaky coax not only wastes RF which never reaches the antenna, it also can pick up interference over its entire length.

Gaps in shielding, especially in high power installations, and poorly soldered or loose RF connectors should also be corrected to eliminate leakage and possible interference.

The junk box solution to visual detection of stray RF is illustrated in **Fig. 1**.

Construction

Making the RF Sniffer is simple. A small diameter wood dowel, or a stiff wire cut from a coat hanger, about two fed long, has the NE-2 neon bulb and 120k Ohm resistor attached at one end with tape. The glass portion of the neon bulb must not be covered because it indicates the presence of RF.

A pair of wires connected to the neon bulb and resistor should be taped along the dowel or stiff wire, leading to the end where the 500k Ohm or one megohm potentiometer is taped or otherwise fastened. A piece of wood or plastic, or a long loop formed in the end of the coat hanger wire, can serve as a handle. The AC line cord is connected to the pot and the wire from the resistor at the handle end of the sniffer and all connections taped to prevent accidental contact.

Adjustment and Operation

Plug the sniffer into a source of 117 Vac. Observe the neon bulb while adjusting the pot. As resistance is decreased slowly, an orange glow will appear around one of the two electrodes in the neon bulb. A further decrease in resistance will result in the orange glow surrounding both electrodes.

Slowly back off the pot until the orange glow is again around only one electrode. Do not readjust the pot from this point!

Using the sniffer as a probe, with the transmitter producing power, investigate coax connectors and jumpers, coax runs, ac wiring in the shack or elsewhere in the house where RF is suspected, while observing the neon bulb.

When leaking RF is detected, the orange glow in the neon bulb will flicker and surround both electrodes.

If RF seems to be detected put the probe back and watch the neon bulb. If the glow retreats to surround only one electrode, RF leakage is present where detected. If, however, the orange glow continues to surround both electrodes, readjust the pot so it is visible around only one electrode and recheck for RF leakage. Because transients and other minor disturbances on the ac line are common, they can cause erroneous indications of detected RF when the sniffer is set at its most sensitive point.

Conclusion

This gadget is not frequency sensitive. It will work a well at UHF as it does at HF and even the TV horizontal oscillator frequency. It is extremely sensitive to low levels of RF. Best of all it is cheap, and can be put together from the usual junk box contents.

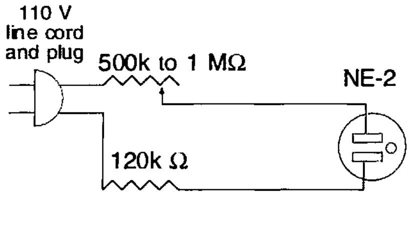

Fig. 1. How simple can you get?

Line Voltage Monitor

A one-hour construction project with a parts cost of under $5!

J. Frank Brumbaugh KB4ZGC
Box 30
Salinas PR 00751-0030

There are a number of 0-150-VAC meters available, but they're difficult to read when you're looking for small line voltage changes. A much more easily read meter is a suppressed-zero, expanded-scale meter which displays only voltages between 90 and 130 VAC. It can be read at a distance and at a glance so you can take action should your household voltage swing too high or too low. The simple circuit described here uses only five common components and can be constructed in less than an hour. The total cost, not including a box, should be less than five dollars.

Background

Power companies attempt to control both the level of AC voltage and frequency delivered to their customers. Though limits on both are established by regulations, some companies are better than others. However, as well all know, they have occasional problems which can possibly harm your equipment.

"Brownouts," common in urban areas in the US when air conditioners or electric heating systems require more power than anticipated, result in lower voltages being delivered to homes. Occasional overvoltages occur when power is switched from one substation to another, or to another point on the national power grid. Although nominal AC voltage in the US is 117 VAC, this can vary between 105 and 130 VAC, while remaining within specifications. Most household equipment is designed to tolerate excursions within this area. However, AC voltages lower and higher than these accepted limits can cause problems with your ham equipment.

AC line voltage can often fall as low as 90 VAC and stress AC operated motors such as cooling fans in amateur transceivers and RF amplifiers, damaging expensive power transistors and amplifier tubes.

High voltages, above 125 VAC, can burn out electric motors. Also, the increased peak voltages applied to filter capacitors, regulators, and transistors in power supplies, especially if the filter capacitors are already operating at or very near their rated working voltages can explode an electrolytic capacitor.

Such high voltages also increase the power dissipated as heat in the power supply transistors. This can cause extra heat at their junctions, causing them to fail, and thus applying a much higher unregulated DC output voltage to your station equipment. This can cause expensive damage.

How It Works

Fig. 1 is the circuit diagram. AC voltage applied through the line cord is halfwave rectified by D1 and applied to zener diode D2, which greatly reduces the peak voltage. Capacitor C1 acts as a poor filter and the partially filtered pulsating DC voltage is applied to meter M1 through meter multiplier trimpot R1. When calibrated, the AC line voltage is continually indicated on M1.

The value of C1 controls the voltage end limits. If you use a different meter, or wish a different voltage range, try different 150-volt capacitors in place of C1. Be sure C1 has at least a 150-volt rating. Its type is immaterial.

Construction and Calibration

The meter should be mounted in an enclosure to prevent any accidental contact with the AC voltage, which can be lethal. A plastic or metal box can be used. The few components can be mounted on a terminal strip. R1 is best attached to either the rear of the meter case or the interior of the enclosure, using epoxy, superglue or hot glue.

Look at your meter scale. With luck there will be four main divisions. If not, carefully take the meter apart and divide the meter scale into four equal, 10-volt divisions, using a fine tip felt pen. Mark these points 90, 100, 110, 120, 130. Reassemble the meter and mount it in its enclosure.

If you are unfamiliar with disassembling meters, please see my article, "Use Those Surplus Meters," *73 Amateur Radio Today,* January 1992, page 42. If you can't locate a copy locally, the publisher can supply back issues or article photocopies.

With your meter scale properly calibrated and all parts mounted in the enclosure, adjust R1 to maximum resistance. Using an accurate AC meter—a digital multimeter is preferred for accuracy, but a V-O-M can be used—measure the AC voltage at the nearest outlet, and note this value.

Plug in the Line Voltage Monitor. Being very careful not to touch any points carrying voltage, adjust R1 so the meter indicates the same voltage you measured previously. This completes calibration.

Operation is automatic. When this instrument is plugged into a live 117 VAC outlet it will continually monitor the level of voltage supplied by the power company.

Notes

Be sure the meter you use has a moving coil (D'Arsonval) movement. Do not use an iron vane meter. If you can't tell the difference at a glance, a good rule of thumb is: If it looks expensive, it probably is a D'Arsonval meter. If it is round or square and has a cheap-looking black painted metal case held together with bent metal tabs, it is probably an iron vane meter.

There are similar-looking line voltage meters commercially available costing

about $20. Some of these appear to use an iron vane meter. You can build a better monitor for a lot less money.

A major disadvantage of using an iron vane meter to which a voltage is applied continuously is that they lose accuracy as the movement becomes magnetized. You'll find that, if you unplug one after a year in use, the needle will not return to the left end of the scale. Instead, it will indicate some level of voltage even though none is being applied.

An excellent and inexpensive source of surplus name-brand meters with D'Arsonval movements is Fair Radio Sales, Box 1105, Lima, OH 45802. A selection of five meters (their choice, not yours), Catalog No. 47-84, costs $10. Mostly basic 0-1-mA movements will be in each selection. Usually there will be one, possibly two meters with 100-µA movements. Some may have internal shunts, multiplier resistors, or rectifiers, but these are easy to eliminate, leaving you with the desired basic meter movement. This gets you your meter for only $2, and you still have four more nice meters for future projects! 73

Parts List

C1	0.01-µF 150-volt capacitor,
D1	1N4007 rectifier diode
D2	1N4764A zener diode
M1	500-µA meter
R1	50-kΩ trimpot

Austrian Licensed

The Republic of Austria will celebrate its 1000-year anniversary in 1996 and Austrian hams will be a part of the celebration. This with the government authorizing special call sign prefixes for radio amateurs.

At the request of the Austrian Amateur Radio Society, communication authorities will permit Austrian amateurs to use the prefix OEM for the entire year. Use of the prefixes will be voluntary and the national society will sponsor two on-the-air operating awards in conjunction with their use. *TNX Amateur Radio Newsline*

Instructor Of The Year

Nominations are open for ARRL Instructor of the Year awards, the ARRL Herb S. Brier Award, the ARRL Professional Educator of the Year, and the ARRL Professional Instructor of the Year. Send nominations to your league Section Manager by January 31, 1996. *TNX Amateur Radio Newsline*

Cuban VHF Group Activities

In DX, the Cuban VHF Group is planning some activities to say goodbye to the "old" 1995 and will activate some "new" grids around the country.

From November 22th to the 26th, the group will operate an IOTA DXpedition to "Cayo Jutia," in Grid NA93. This is a little key 2 miles away from the north coast of Cuba's most western province, Pinar del Rio. Operators will be from Italy, Spain, Portugal, France, Mexico, and Cuba.

Operation is planned for 6 meters, 2 meters, and 1,296 Mhz. Other bands will be added if gear becomes available for 220 Mhz and 70 cm. *TNX Amateur Radio Newsline*

Tropo DX

Ken Rameriz KP3XS in Puerto Rico says that the best Tropo event he has seen in a long time occurred the evening of October 30th and was still present at 1 AM EST on Tuesday the 31st. Ken says, via the Internet's VHF Reflector, that he took to the airwaves at 8:30 PM EST and found the band open to Florida. He then proceeded to work every Florida grid down to the Keys. The only grid missed was EL86.

Ken says that he kept hoping one of the Cubans would get on but no luck. He did hear one of the Florida stations work KD4UPF in FM18 and quickly swung the beams North East where his first contact was KM1X in Rhode Island! Ken then went on to work 90 stations in the next 4 hours including WZ2O all the way to 1.2 GHZ!

Talk about a night of unbelievable tropo DX. *TNX Amateur Radio Newsline*

DX S92po

Meantime on the high frequency bands, look for Principie Island on the air from November 21st to December 6th. A group of French operators will sign S92P on all bands on CW, SSB, and RTTY. They will also be active in the CQ World Wide DX CW Contest. QSL via F6KEQ. *TNX Amateur Radio Newsline*

Martian Trivia

A bit of ham radio television trivia via packet from Tim Ertl KE3HT. And this is really going to take you back a few years.

How many of you remember the 1960s TV series, *The Munsters?* No, not the recent movie seen on Fox but the actual black and white TV show that featured Yvonne De Carlo as Lilly and Fred Gwenne as Herman Munster.

Well, Tim says one episode had a ham radio connection. He describes the plot as Herman playing ham radio operator using the call sign W6XRL/4, calling CQ. Then, while tuning around he bumps in to a couple of kids playing as Martians and as usual, things get out of control.

So Herman enlists the help of Grandpa Munster played by Al Lewis. Grandpa has a Radio Direction finder of sorts. Well it's really a transistorized divining rod that they use to find the Martians who are nothing more than some neighborhood kids.

KE3HT adds that it is obvious that the episode was done in fun, but he will bet one of the shows writers was a ham. *TNX Amateur Radio Newsline* 73

Manufacturers, we would like to review your products and report on them in 73. Please contact Ron at 800-274-7373 for more details.

Letters

Continued from page 6

my license. In 1987, I re-tested and quickly acquired my General License again. Late in 1994, I passed the Advanced Class upgrade, and in August 1995 I upgraded to Extra Class. I have had to renew my high school memory of trigonometry, as well as learn how to use a scientific calculator. My main talent is sewing, not electronics, but I passed the test, three months short of being eligible for Medicare. And I understand that keeping the mind active wards off Alzheimer's disease and other maladies. I am very appreciative of the ham community, which has kept the bands active throughout the years in order that those of us who have been less active still have frequencies on which to operate. That means the old-timers. They probably have more stick-to-it-iveness than some of the newcomers. If they have not become bitter through the years, they have more manners than some of the younger generation. And manners speak well for amateur radio. And, off of that subject: May I suggest/request that it would be easier to respond to "Feedback" if the back side of the listing were an ad, rather than an article or printed circuit diagram?

PROPAGATION

Jim Gray W1XU
210 Chateau Circle
Payson AZ 85541

January is seldom a good month for DX—or weather for that matter—and this month is no exception, so get ready for the bad news first.

There may be some very severe geo-physical conditions around the 15th or 16th and the 25th and 26th...give or take a day or two. Be prepared! The *best* days are likely to occur in the first, second, and last weeks of the month, while all else is trending.

However, the days are getting longer and you can expect the higher HF bands will be staying open longer. 80 and 160 meters will still provide excellent DX on the *best* days, and 40, 30, and 20 will do the same.

10–12 Meters

An occasional F2 opening toward the tropics during daylight hours...but, as is usual during sunspot minima, you can't expect much winter activity. Listen and call on the Good (G) or Very Good (VG) days.

15–17 Meters

Short-skip and some DX openings during daylight hours on Good (G) and Very Good (VG) days, particularly during afternoon hours. The band closes early, however.

20 Meters

Fair to good DX during daylight hours, peaking shortly after sunrise for an hour or so, and again in the early afternoon; and closing at, or shortly after, sunset. Short-skip up to 2,500 miles or so during daylight hours. Again, listen on the Good and Very Good days. Check WWV at 18 minutes after any hour.

30 Meters

A strange and unpredictable band! Sometimes like 40 and other times like 20. Your best bet for DX is late afternoon and early evening hours. Short-skip during daylight hours will prevail.

40 Meters

DX to Europe and Africa during late afternoon and toward South America after sunset. After midnight, listen for Asia and the Pacific. Short-skip during days and longer skip after dark.

80 Meters

This should be your best DX band during hours of darkness, peaking around midnight and just before dawn. Short-skip in daytime and longer skip after dark.

160 Meters

Here's another wintertime DX band. Open after sunset, and peaking to the *east* around midnight, and toward the west and Pacific areas near dawn. Band closes during daylight hours due to high absorption of these lower HF frequencies.

Please let me know how these forecasts are working for you. By the way, keep your fingers crossed because 1996 may spell the sunspot minimum of Cycle 22. We can hope, can't we? 73, Jim "XU" 73

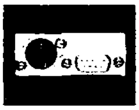
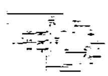
RADIO FUN SECTION

On the cover: Kerry N6IZW microwaving near Mt. Laguna CA to Mt. Union AZ. See story on page 20.

Feedback: Any circuit works better with feedback, so please take the time to report on how much you like, hate, or don't care one way or the other about the articles and columns in this issue. G = great!, O = okay, and U = ugh. The G's and O's will be continued. Enough U's and it's Silent Keysville. Hey, this is *your* communications medium, so don't just sit there scratching your...er...head. FYI: Feedback "number" is usually the page number on which the article or column starts.





73 Amateur Radio Today (ISSN 1052-2522) is published monthly by 73 Magazine, 70 N202, Peterborough NH 03458-1107. The entire contents ©1995 by 73 Magazine. No part of this publication may be reproduced without written permission of the publisher, which is not all that difficult to get. The subscription rate is: one year $24.97, two years $44.97; Canada: one year $34.21, two years $57.75, including postage and 7% GST. Foreign postage: $19 surface, $42 airmail additional per year, payable in US funds on a US bank. Second class postage is paid at Peterborough, NH, and at additional mailing offices. Canadian second class mail registration #178101. Canadian GST registration #125393314. Microfilm edition: University Microfilm, Ann Arbor MI 48106. POSTMASTER: Send address changes to *73 Amateir Radio Today*, 70 N202, Peterborough NH 03458-1107.

Contract: The merest glance at this constitutes a binding legal contract between you and Wayne Green, the publisher, wherein you guarantee to make a list of at least ten interesting things you can talk about on the air and post that list next to your microphone to help prevent you from being a monumental bore. You further agree not to mention the make or model of your rig or antenna. If you should fail on the above, your punishment will be the reading of at least five pages of Section News in the advertising catalog section of a 1994 issue of QST.

NEVER SAY DIE

Wayne Green W2NSD/1

So Few Pages

There are so many interesting things to write about that I wish I had 20 pages a month. If I could stop myself from writing so much I'd look into setting up a web page. But the more I read and talk with the experts in many fields, the more I want to let you know what's going on.

This month I'll bring you up to date on the incredible developments in cold fusion. And my theory for why cold fusion is happening. I've got what seems to me the first rational explanation for why we have inertia and gravity. But then most people don't know that scientists don't know.

And I want to tell you about my drive around London on a magnet-powered scooter which defies the law of conservation of energy. And about my trip to Stonehenge.

I've some advice on how to build ham club attendance, and more news on ways we're slowly poisoning ourselves. This time its those pesky fluorides.

I've been doing a brisk business in my booklet of editorials written for *73* that haven't yet been published. It's running 32 pages of even smaller type than this, but I'll have to expand it to keep up with my output. Some of the material is ham-oriented. There are 46 of my editorials in the $5 booklet, but it'll probably be up to 60 by the time you read this — if the mail from that W6OBB radio talk show interview I'll be telling you about ever slacks off!

Cold Fusion Update

It's been quite some time since I've written about what's been happening in the cold fusion field. It has not been standing still.

For those with short memories for trivia, the cold fusion phenomenon was announced by Professors Pons and Fleischmann of the University of Utah in 1989. They claimed that by passing a small amount of current through a palladium cathode in a lithium and deuterium electrolyte they had produced a substantial amount of excess heat for which there was no good chemical or physical explanation.

"Yep, one thousand times more output than input!"

Several universities tried to replicate the experiment. Most failed, triggering a media stampede ridiculing Pons and Fleischmann. The U of Utah canceled their funding and dumped them. What wasn't made public was that many of the universities which "failed" to confirm the cold fusion process were getting generous funds for hot fusion research. If cold fusion was really true, the schools involved stood to lose millions. Also hushed up were the reports from several universities confirming the P&F results.

The controversy pretty well stopped the funding for American cold fusion research. Scientists in other countries, with Japan leading, continued to pursue the idea, getting substantial government funding for their work.

In late 1993 I became convinced that despite the media reports, cold fusion was not just a fact, but looked like it would eventually be able to supply energy at a fraction of the cost of fossil fuels such as coal and oil, and without the pollution these sources generate. With known fossil resources dwindling, this new energy source was coming along at the right time. But how would the world change if energy could be generated at a tenth or less the cost of energy today? Imagine cars requiring almost no fuel. Planes. Ships. Space ships.

So I attended the Fourth International Conference on Cold Fusion (ICCF-4) on Maui in December 1993, where I announced I would be starting a magazine to help researchers communicate, to provide a forum for physicists to argue over the theory of what was going on, to help newcomers to the field come up to speed, and to allow potential investors to find the ground floor scientists to support.

The field was alive and well during 1995, with international conferences being held in Boston (MIT), Monaco (ICCF-5), Bombay, Tokyo, Molise (Italy), and Sochi (Russia).

The leading light in the US is Dr. Jim Patterson of Sarasota, an inventor who got patents on his innovative cold fusion cell. He made microspheres of plastic and coated them only microns thick with palladium. The result was that his cells were able to start generating excess heat in minutes instead of days to weeks, as required by the use of solid palladium. He demonstrated his cell at Monaco, with the cell and instrumentation out in the open for everyone to check. His cell was generating about six times more energy out than it took to trigger it. And he was using plain water instead of the much more expensive deuterium!

Six months later, at a fusion conference at the University of Illinois, his demonstration cell was turning out 100 times more energy than required to run it! This was confirmed by the scientists from 35 countries attending the conference.

Two months later, in December 1995, the Patterson Patented Cell (PPC) was demonstrated at the Power Gen conference in Anaheim, where the top brass from power companies all around the world saw Jim's cell perking away, with one watt of power going in and 1,000 watts of heat being generated as a result. Yep, one thousand times more output than input! Let's see the cold fusion critics attribute that to errors in measurement. Jim's company is Clean Energy Technology Inc. (CETI). How'd you like to have a piece of *that* action?

Yes, the utility bigwigs sure paid attention. Several major companies are dickering with CETI for licenses to develop power systems using the Patterson technology. And CETI will get a piece of the action on any developments of their basic system. Early investors could reap billions from a fairly modest investment. The readers of my *Cold Fusion* were alerted so they could get in on the ground floor of this one, with the full information on the PPC in issue #7, back in March 1995.

Of course it's going to be years before we no longer need power lines, are running around with cold fusion powered wrist communicators, and so on.

The Heat Source?

The standard model for the atom and classical physics doesn't explain what's happening. This is one reason the scientific establishment pooh-poohed the P&F claims, humiliating them. So when a division of Toyota came along and offered to build them the laboratory of their dreams anywhere in the world, they ended up on the French Riviera. And Toyota ended up with a good chance at having the first car needing no fuel. We'll see. P&F are now being very secretive about their progress. That could be because they aren't making much progress, or because they are.

I've run a series of articles in *Cold Fusion* by some top scientists on what they think is going on. My own theory is that the excess heat is the result of a transmutation of elements in the palladium metal's lattice. Yep, alchemy. This would explain why there's some helium being generated, but not enough to explain the amount of excess heat. The universities of Illinois and Missouri are checking the Patterson cells to see if there are any other transmutation products. I predict they'll find beryllium, which will be a product of hydrogen and lithium, and some silver resulting from the transmutation of palladium and hydrogen. These reactions would easily account for the excess heat being generated, as well as the lack of radioactive products. This is cold fusion, working from the lower end of the periodic table, not cold fission, working from the top down.

The reaction is kept gradual since it is happening in the metal lattice. A fast reaction could be explosive, and we've seen some signs of that potential, with some lab experiments blowing up. One killed a scientist who was in the wrong place at the wrong time.

Inertia and Gravity

What *is* matter? Well, it's energy of some sort. We really don't know what matter is (yet), but like quality, we know it when we see it.

The cold fusion reaction has called into question the so-called standard model of the atom. A lot of verities are being called into question these days, despite the ear-plugs

LETTERS

From the Ham Shack

Jack Conway N5YIS. I never go to hamfests, so I thought that I would never have an opportunity to hear you speak. When I read in *73* that you had a tape for sale, I just had to have one. Here is my five bucks: After reading years of good money-making ideas from you I thought I would send you two that you can have free of charge. Your offer to sell back issues of *73* was tempting, but like most people I don't have room for any more magazines. I do, however, have room for more CD-ROMs, so why don't you scan all your back issues onto CD ROM's and sell them? I know I would buy them just to read all the editorials. Why don't you put your audio publishing house to work putting together a Morse code CD? Reading the different magazine I read, I have always wondered why nobody put together a Morse code trainer on CD. Most CD players have a random play feature. I think it would be the best medium for practicing code. Keep cranking out the quality editorials.

Sure, I'll bet I could sell dozens of CD-ROMs of the back issues. Let me know if you'd like to scan in the 50,000 pages for me. Or maybe I could get some retired ham to scan in my over 1,000 editorials. I'll bet I could sell scores of those on a CD-ROM. We did a CD-ROM listing of every known CD back in 1989 and sold dozens of 'em. We even scanned in the color covers for hundreds of 'em, and had sample tracks of the music. It sold like cold cakes. The code? All it takes is one one-hour tape at 13 per to learn the code from scratch. And one at 20 wpm for that speed. Why would anyone put an hour of code on a CD when a tape does it just fine? . . . Wayne)

Dave Kaun N9KMY. It is truly time for our hobby to move into the new technology age. We need to substitute application of technical skills for Q&A manual memorization and the copying of the code as a method of advancement. Memorization, popular as a teaching method in previous generations, is no longer the way learning takes place today. While we expect our youngsters to understand and apply huge amounts of technical information, why are we still requiring memorization in amateur radio? Let's make our hobby a natural learning progression for technically literate students interested in what ham radio offers.

After many years of being involved with electronics as a hobby and as my career, I became a Technician before the no-code license was offered. To me the technical side of the hobby is much more important, though I would enjoy working HF if it were not for the artificial barrier the code presents. I find it quite interesting that many who once long ago learned the code can't carry their side of a technical conversation equal to the license they hold nor even remember the code well enough to use it. More than memorization is needed today to understand technology; just ask any engineering student if formula or fact memorization is enough. Learning and understanding applications is much more important. We need to follow that same methodology of learning in amateur radio. Keep up the good work and the excellent magazine.

Philip Weaver VS6CT. Wayne, it's been awhile since our paths crossed. I am leaving for the CRSA DX Convention in Beijing later today and was remembering how we met in the BY1PK Radio shack in Beijing back in 1984, when I was assisting with the communications associated with the Hong Kong-to-Beijing "555" Car Rally. I retired from the Hong Kong Government in February of this year and I have not stopped since. I will be dashing around Asia for the next two months, with visits to Bali, Thailand, Hainan Island on the South Coast of China, and Kota Kinabalu. I sold my flat here in Hong Kong and will be leaving for England in December to join the QE2 out of Southampton for a four-month round-the-world cruise. I am hoping that I will have managed to organize the setting up of a ham station on board and am awaiting word from Chip Margelli of Yaesu to supply me with a radio as the official sponsor of the station. I'll return to England in mid-April and expect to be back out here in Hong Kong in late May to try to find a flat where I can put some decent antennas on the roof. I am very bullish and optimistic about the future of Hong Kong, which is why I want to stay here, apart from the advantages of being somewhere that I know. I've enjoyed living here for 22 years. I just hope that my faith will be justified in the future. I still read your editorials with enjoyment, I just wish that they could produce more results. Keep at it Wayne.

Phil, I hope your trust of Beijing not ruining Hong Kong is justified. It's too bad the changeover isn't in 10 more years, after China has had an opportunity to adjust to capitalism. . . Wayne)

Sharon Cenna KB8VXL. I just finished reading your September editorial. You have a lot of valid comments. You ask why ham radio isn't growing and why so few hams read the magazines. Well, I'm a new ham and I've found very few hams willing to Elmer (or Elmira). No one is volunteering to give demonstrations or workshops at the local schools or clubs. Even giving a demo on a parent/teacher night could be fun and enlightening. As for community service, CB usually provides help faster than 2m. All this prevents young people from learning about amateur radio. Have you heard of any ham groups anywhere in the country teaching kids how to come up with their own electronic inventions, techniques, or computer connections? I guess the only person I can change is me, so I better get going doing something creative in my own square of dirt, then share it with the next person I meet, and keep going.

I keep scanning the club newsletters, hoping to see some signs of responsibility for growing our hobby, as you've suggested. Nope, they're all busy having fun. No school or local club demos. Now and then a group will put on a demo at a shopping mall, but those that I've visited were very visitor unfriendly. Sure, the hams were having fun, but they made no effort to communicate this to visitors. I've talked with school kids in many schools about the fun we have to offer. I've talked to over a hundred service clubs about it all over New Hampshire and Massachusetts. But I feel I'm waging a one-man fight, with no visible support. . . . Wayne

Glenn Hammond Sr K4YDG. I have been a loyal *73* reader since the first issue came out in 1960. I was 12 years old at the time and earned the money to buy the magazines with my morning paper route. I also read *6-Up*, your VHF magazine, until it ceased publication. You made enough of an impression on me that I earned my Novice ticket in 1960 and steadily became more interested in electronics. During the Vietnam War

QSL Contest Winner!

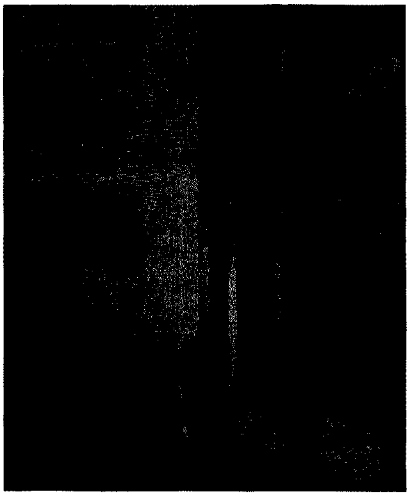
Page Perrin KG6JY combines two of his hobbies in this QSL. Page says, "By combining my two favorite hobbies, amateur radio and hang gliding, I'm able to have much safer and enjoyable flights. Air-to-air communications with other ham-licensed pilots about lifting air conditions, and air-to-ground contact for critical wind information just prior to landing make me glad I became a ham. Packet GPS will allow hang gliding pilots to fly cross-country and automatically report their position to their chase vehicle, or in an emergency to rescuers. Staying up for hours and flying hundreds of miles has become commonplace in the sport. That's Mt. Shasta in Northern California behind me. It is about 80 miles away."

QRX . . .

Number 8 on your Feedback card

ITU Nixes Code Change

New Zealand proposed the deletion of the Morse code requirement from the ITU amateur radio regulations, but the move was opposed by the American delegation, which was notable for the number of ARRL members on the delegation. The matter has been tabled until some future ITU conference. The success of the ARRL in preventing this move was expected, since it has rather tight control over the International Amateur Radio Union (IARU). But a growing number of countries would like to have the ITU amateur regulations more in tune with today's technology and not continue as a monument to the long past.



Nine-year-old Brian Kearns KC7MLW operating the CARL station.

Science Center Ham Exhibit

The Center for Amateur Radio Learning (CARL) successfully finished its first summer at the Arizona Science Center. The exhibit was located within the Tech-zone at ASC. The station featured an HF installation with a triband beam and a VHF packet station. With the help of over 40 volunteers from the Arizona amateur radio community who volunteered their time, visitors were able to speak with hams around the world.

The next CARL goal is to set up a permanent station at ASC's new facility, which is scheduled to open early 1997. The station will be state-of-the-art and will employ as many modes of amateur radio operation as possible, including satellite, HF, packet and ATV. Along with the station there will be an area set aside for visitors to build electronic projects such as crystal radio sets.

CARL is in the Arizona Science Center, which is dedicated to exposing children and adults to science and technology in a friendly hands-on manner. Approximately 500,000 visitors pass through ASC each year, with over being children. Technology has become an essential part of our society and exposing children to radio communications and electronics can lead to a lifelong interest In science. This is an opportunity not only to recruit new amateur radio operators, but also a project which can lead young people to careers in high-tech fields.

CARL is seeking help in raising the $50,000 needed to complete the project. Barry Goldwater K7UGA and Lou Grubb WA7HZO have offered their names and support for the project. Donations to the project are tax-deductible, and donated radio equipment may either be used at the station or sold for proceeds. If you would like to help please call Ralph Barr W0DNO at (602) 582-8208. In the Phoenix area join their net every Tuesday at 8:00 p.m. on 145.35 MHz, via the DAWN repeater. *TNX Rick Horwitz AB7FH.*

Hooray Oregon!

Features with young hams are what we need in every newspaper in the country. Congratulations to the hams in Oregon for getting this priceless PR in *The Oregonian.* The article points out how much fun the youngsters are having with inexpensive equipment, while learning about electronics and making new friends. Thanks to Steve Brose WA7EZB for sending the clipping.

RADIO-ACTIVE TEENS

Ham Towers Legalized!

Well, at least in Massachusetts. Governor Weld signed H-2782 into law. It states that, "No zoning ordinance or by-law shall prohibit the construction or use of an antenna structure by a federally licensed amateur radio operator. Zoning ordinances and by-laws may reasonably regulate the location and height of such antenna structures for the purposes of health, safety, or aesthetics; provided, however, that such ordinances and by-laws reasonably allow for sufficient height for such antenna structures so as to effectively accomodate amateur radio communications by federally licensed amateur radio operators and constitute the minimum practical regulation necessary to accomplish the legitimate purposes of the city or town enacting such ordinance of by-law."

Don't just sit there nodding in agreement, get your legislature to enact a similar law to help back up the FCC's PRB-1.

Updates

In the November 1995 issue, page 20, "A Simple Wattmeter." Yes, the diodes D1 and D2 are drawn backwards. The author had 'em wrong and it didn't get caught until a reader spotted it.

In my November editorial, page 74, I gave the phone number for Marcus Books. Since then the prefix has changed from 416 to 905. You can order *Maximize Immunity*, and other Marcus books, via 905-478-2201. Good luck on finding anyone there to answer. But you really should read the immunity book for your and your family's health, no matter...Wayne.

Feedback

In our continuing effort to present the best in amateur radio features and columns, we recognize the need to go directly to the source—you, the reader. Articles and columns are assigned feedback numbers which appear at the top of each article/column's title page. On your QSL card (or a regular postal card or letter), please write the number of the article or column about which you are critiquing and include the cover date of the magazine. Make it simple, indicate: Great, OK, or No Way. And let us know what you want to see more of or less of. If you want to write something at length, that's okay too. You may critique as many articles or columns as you want, but please only mention one article or column per card.

Do we really read the feedback cards? You bet! The results are tabulated each month, and the editors take a good, hard look at what you do and don't like.

Each month we'll draw a card at random. If yours is picked, you'll receive a one-year subscription (or extension) to 73. If you use your QSL card for your critique, we'll consider it also part of our QSL contest.

To save on postage why not send your card in an envelope with a damning or praising letter to the editor while you're at it too.

Send to "Feedback" at 73 Magazine, 70 Route 202 North, Peterborough, NH 03458.

Satellites, Weather Imagery, and Sunrayce '95

There's an Indiana Jones in each of us.

James R. Buchanan K8WPI
9549 N. 17th St.
Kalamazoo MI 49004

Anyone can have an adventure. All you need is a little willingness and a special skill or two. Then, be ready when fate drops an opportunity on you.

Winter 1987: The Seed Is Planted

The north winter wind was covering the woodpile with snow as I slogged back to the house with another load of logs for the fire. Entering the house and shedding a dozen layers of clothes, I opened the door to the wood stove to feed the flames of warmth. As the fire glowed through the glass door of the stove, the image on the TV screen was almost as bright. Minuscule cars, not much more than oversized skateboards, powered only by the sun, were winding their way across Australia from Darwin to Adelaide. A PBS special on the first World Solar Challenge caught my attention. I sat there spellbound for the next hour. This was the adventure of a lifetime. Twentieth-century Magellans, Byrds and Huck Finns were embarking on a technological revolution while sharing an adventure that dreams are made of.

The first World Solar Challenge caught my attention with a passion. I knew then that if I ever had the opportunity to become involved with such an event, I would jump at the chance, whatever the cost or consequences might be.

Fall 1992: Germination

The September meeting of the Kalamazoo Amateur Radio Club started with the obligatory business meeting, laden with the excitement of the August minutes and the treasurer's report. As the evening droned on, I began to fade from focus when I thought I saw Rod Sterling stand up at the chairman's table. A familiar voice announced that Western Michigan University was looking for a communication specialist, and was interested in investigating weather reconnaissance for Sunrayce '93 next summer. What? Was this the chance for me to don Indy's fedora and head off into the sunset in search of the solar grail? It took about two nanoseconds to know this was what I was looking for. I would make the commitment for myself and my wife, right there on the spot. I approached Rod (actually J. C. Schneider KF8TJ, a neighbor of Dick Schubert, the father of WMU's solar racing project) and advised him to have the WMU folks get in touch with me; I'd see their needs were met!

I spent the fall and winter of '92 reading every book written on anything related to watching the Earth from space and weather services in the RF spectrum. I started planning the ultimate mobile weather reconnaissance vehicle. By June, I was on the road with the most sophisticated, privately owned original-source solar reconnaissance vehicle on earth, as far as I knew.

Bearing Fruit

After successfully completing Sunrayce '93 from Dallas to Minneapolis with WMU, I was approached by a dozen hopeful schools about providing similar weather imagery and data for Sunrayce '95.

Sunrayce is a biennial event hosted by the Department of Energy, General Motors, National Renewable Energy Lab, and a dozen other automotive-related industries. The concept is to promote the technologies and growth of solar power. Universities, colleges, technical schools, and even community colleges from the US, Canada, Mexico, and Puerto Rico design, build, and race solar-powered vehicles across the country. The cars must meet minimum highway safety standards. Battery storage and solar collector maximum specifications are set by the race committee. The cars must be powered 100% from the sun. Excess energy collected from the solar array may be stored in batteries for use at a later time. For the most part, the race course is primary and secondary highways; little time is spent on the expressways.

There is a charging period each morning, this year from 6:00 a.m. to race start at 10:00 a.m. local time. The cars leave the starting line in the order of finishing the previous day's run, or in their qualifying position the first day. Cars are started in one-minute intervals, to spread them out over the course a bit. A mandatory midday stop provides the opportunity to change drivers, make minor

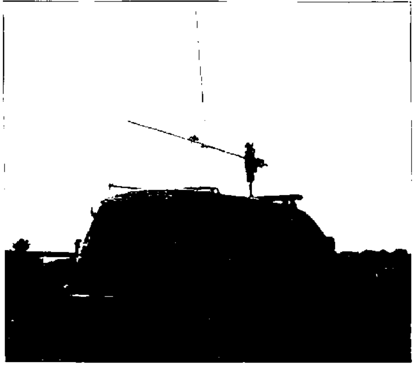


Photo A. "MONDO-MITSU" mobile antenna farm, Fort Smith, KS.

repairs, and to make a personal pit stop. This 15-minute stop is "off the clock," so all cars leave the midday stop in the order they arrived. A common end of day location is the finish line for each day. Charging is allowed until 9:00 p.m., when the cars are impounded overnight. The lowest elapsed time for the day's route establishes the day's winner, with the overall race winner being the team with the lowest accumulated time over the course of the race. This year's race was from Indianapolis, Indiana, to Golden, Colorado, just over 1,100 miles.

Each team has a lead and chase vehicle, and the solar car is "cradled" between these two buffers. With at least a three-car entourage for each car, passing can be a real challenge, but safety is paramount. Solar cars, with electrical consumption of less than a blow dryer, are fairly fragile. A broadside collision would almost certainly be fatal. The lead and chase vehicles provide higher visibility for the diminutive racers on rural country roads. The pace is determined by the strategists in the support vehicles; the race car driver is to keep the car on the road, drive as smoothly as possible, and follow instructions fed by teammates via radio. Each team is accompanied by an "official observer," provided by the sponsors, who makes sure the team follows all applicable traffic laws. Infractions are met with penalties, representing time added to the actual drive time each day.

***Photo B.** Inside view of the operating position in the back seat. Note power monitor control panel at bottom, keyboard drawer for storage while in motion, and printer on top of rack.*

With limited energy, a fixed schedule, tremendous competition, and years of work riding on the performance of each team, no one takes the race casually. Some schools have teams approaching 100 people in all aspects of the project, and may spend hundreds of thousands of dollars in design, preparation, and execution of the race. With such great stakes, every advantage available is considered and used, if possible.

As the total power requirements for the race car must come from the sun, the weather plays a very important role in how strategy is applied and how the day's course is run. Today and tomorrow's weather will affect the collection capabilities of the array. The daily course, whether hilly, flat, gradual incline, or steep slope, will determine the energy consumption of the car. Small towns with intersections, traffic lights, and railroad crossings all eat into your available energy supply. If you decide to pass another car to advance your position, you must weigh the gains versus the loss in energy. You must know not only how much energy you have stored, but how much you are currently using, what you expect to gain at the end of day, charging time, and what your use and charge rates will be tomorrow.

Weather Reconnaissance and Strategy

My participation was to provide onsite, real-time weather information and imagery. Although as a support vehicle I was required to drive an alternate route, radio contact and midday rendezvous enabled us to exchange the required information.

My Mitsubishi Montero, named "Mondo," was equipped to gather as much information as practical, although I have been told I was far beyond practical. The polar orbital U.S. NOAA and Russian MET series satellites operating on 137 MHz offer very detailed information on a fairly steady basis. With four American and two Russian satellites providing images, the selection would be great. I would also use terrestrial-based charts, graphs, and rebroadcast images from the GOES satellites.

For Sunrayce '93, the equipment rack in the back seat of Mondo held an HF ham band transceiver, general coverage receiver, antenna tuner, FM fax demodulator, VHF satellite receiver, satellite demodulator, computer, RGB-to-NTSC video converter, video monitor, high resolution large format video printer, 8mm taperecorder, plain paper printer, GPS receiver, and work lights. The antenna complement was the external GPS antenna, 144/440/900 amateur band/cellular antenna, 160–10 meter amateur band antenna, 150 MHz business band vertical, and a collapsible turnstile antenna for the APT satellites, similar to the "Zapper" as described in Ralph Taggart's *Weather Satellite Handbook.* This antenna was built on the principle of a blind person's cane, held together internally with elastic straps. The antenna would collapse to about 4" in diameter and 3' in length. A good "shake" and the antenna would snap into position. I would then place it in a boot atop the car and catch the satellite passes. This allowed me to run up and down the road without a satellite antenna on the car. It kept the competition guessing about what I was doing, as there were no telltale signs. Although the Zapper worked, it was less than impressive, at least by my standards. The team was happy, we had usable images, excellent weather prediction information, and that was that!

Mobile Imagery

As the months after Sunrayce '93 wore on, I became more interested in the possibilities of mobile imagery. I already knew I was going on Sunrayce '95, I just didn't know with whom, yet. I started to investigate the possibilities, while making preparations for Polarquest-'94 (don't ask and I won't have to tell you, but suffice it to say it had to do with the North Pole).

For serious APT images, especially the lower-angle passes which provide more east/west information, I needed more of an antenna. I also needed to get rid of more noise generated from equipment within Mondo.

Woodhouse Communication provided me with the answer, a circularly polarized yagi made especially for the 137 MHz band. Available in a rear-mount configuration, it was ideal for mobile installation as it eliminates the large vertical turning radius needed for "over-the-top" passes. The idea of a yagi mounted on a vehicle may seem a bit like overkill, but let me share with you

the essence of what I have learned over the past three years of mobile and fixed location imagery.

Nobody Knows the Noise I've Seen

There is nothing that can kill the quality of an image like noise! As if some deity out there just doesn't want us to mess around with APT satellites, every conceivable obstacle has been built into the system. Just look at the receiver bandwidth required for APT images. Forty kilohertz lets in a lot of noise. Sure, you can easily copy a signal of 1/2 microvolt on your 2 meter handheld, but you only have a 5 kHz bandwidth. The wide bandwidth, and the fact that 1/2 microvolt is more signal than frequently available for your satellite receiver, presents a challenge. Throw in the numerous high power front-end overload sources near the frequencies, and you need all of the help you can get. No, this is not rocket science, but LEO satellite reception at home is an entirely different world than from your car or van. Noise comes from all sorts of sources. I don't know what the criteria for meeting FCC Part B radiation is, but evidently it is just short of nuclear impulse.

The computer used to display the image, or to control the tracking system is the largest source of noise, yes, even up to 137 MHz! I have spent hours hand-selecting individual boards for use within the computer, substituting different brands of the same type of board, searching for the quietest one. There are significant differences. All input/output lines are decoupled with ferrite beads. The video monitor is another great source of noise. The more sophisticated the display, the greater the noise. This year I needed ESVGA to provide 1024 X 756 X 256 resolution. Big-time display, big-time noise! My demodulator has

Photo C. D-Day -2, final preparations done, ready to hit the road.

been tweaked like an Indy race engine, and additional decoupling and shielding has been added to the point where the manufacturer's original cabinet is only an outer shell, covering the added interior shielding. All power supply lines are shielded and decoupled. If you are afraid of diving into your expensive commercial equipment for which you don't have a schematic, this may not be the "motor sport" for you. Many pieces of equipment have feedthrough networks added to their power lines. All cables are insulated to prevent ground loops. Cables within the rack are separated by function to provide additional isolation, and some cables are actually laced into the position which radiates the lowest amount of noise. Power distribution using shielded wire is routed via separate circuits with individual circuit breakers for different functions. Each piece of equipment is bonded via an individual ground wire to the common rack/chassis ground. Remember, a good DC ground probably isn't very good at 137 MHz.

If you use a desktop computer, you need 110 VAC for power. Power inverters are a whole new breed of noise generators. I have found the new high-tech class D switching supplies will generate noise from 60 Hz to over 400 MHz. Even the HF ham bands become worthless with the buzzing drone of this type of inverter. Maybe there is a quiet one out there; however, I have tried five different inverters, all with the same results. The inverter I use is an antique bi-stable multivibrator type with a real E-I core transformer which goes a long way to limit its spread-spectrum capabilities. I never was successful in eliminating the rampant microprocessor noise in my new all-band all-mode HF transceiver; I just turned it off while catching passes. The only pieces of equipment which have not caused external noise radiation are the Vanguard WEPIX 2000B receivers, the AEA FAX, the KAM TNC and the previously used TS-820 and FRG-8800. With three major outings over the past three years, I have spent hundreds of hours determining noise sources, and eliminating them. If I can be of any assistance to you in similar endeavors, I hope it will be in preparing you for the challenge at hand, giving you some clues as to where to look for noise, and what may need to be done.

The problem is always the proximity of the noise source to the antenna. I have measured noise reduction of 40 dB, enough to eliminate the problem, just by moving the antennas 20' away from the car. Unfortunately, that is not a practical solution for these events. Your antenna will be within a few feet of the noise sources, so you must keep your nose to the grindstone.

Practice Makes Perfect

My planning for Sunrayce '95 started in April 1994, after making a commitment to Queen's University of Kingston, Ontario, Canada. There were a few "givens" to be reckoned with. The sunspot cycle would be at the bottom of the curve in June 1995. This means HF communication would be the worst it could be. As HF signals from numerous sources are absolute essentials, the HF equipment and antenna would have to be upgraded, and offer the highest performance available. I purchased a new FT-900 HF transceiver to replace both the old transceiver and the general coverage receiver. This saved a lot of space, reduced power consumption, and offered tremendous flexibility. The SGC-QMS antenna was selected as the HF antenna of choice. This superperformer provides complete coverage from 1.8 to 30 MHz. This would allow peak performance on the ham bands, as well as general coverage receiving. Always preparing for the worst, I packed a wind-up longwire. The "SMART-TUNER" in the QMS can tune

Photo D. Almost 4,000 later, on the triumphant return through the Badlands.

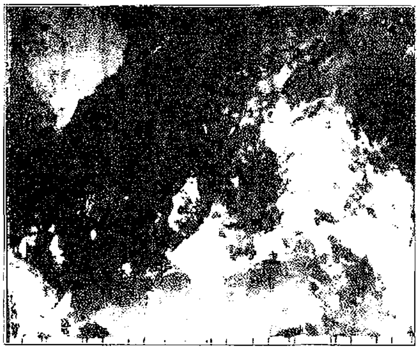

Photo E. NOAA satellite image showing the well-defined "V" cloud formation of a severe thunderstorm, just ahead on the race course.

an end-fed wire if more antenna is needed due to poor conditions. The VHF antennas would also need to be improved. Although I did my best to keep my activities quiet during Sunrayce '93, people figured out what I was doing, and I knew the competition would be inspired from Mondo '93. I would have to assume teams would try to emulate my efforts; I had to be at least a generation ahead of them. The APT-4X4RM I used on Polarquest was remarkable. At that time, I manually tracked the satellites. This year, I would use the computer for auto-tracking. I did not hesitate to install the APT-4X4RMX yagi and the APT2CP turnstile from Woodhouse. Keep in mind, putting full-sized VHF antennas on a car and running them down the road up to 10 hours a day, even in the rain and hail, requires extremely tough antennas. Weatherproofing is also important. A gentle shower on your roof becomes a gale force storm at 65 MPH! The possibility of full days of rain must be considered a reality. The antennas must perform, regardless!

The new equipment rack layout was started in December, with preliminary tests made as soon as the weather was decent. Being one of those Midwestern conservatives, I don't trust to luck, I trust to knowledge. The equipment rack and antennas were permanently installed on Mondo in April, which allowed two full months of fine-tuning, practicing, and preparing for any scenario.

On the Road

My team advised me about a month before the race that they had made arrangements for a professional meteorologist to accompany me. He would be bringing a small dish for data acquisition. *Wow!* Now this was really getting interesting.

Pam (my wife) and I arrived in Indianapolis on Saturday afternoon; the race started Tuesday. On the way to Indy, we continued "practicing" by capturing near overhead passes (###25) while on the move. After a casual look around at the solar cars, and a brief meeting with our team captain, we were introduced to Etienne Gregoire, the meteorologist supplied to the team by Environment Canada. ET, as he is called, is one of those people you like right off the bat. A mild manner, a good sense of humor, and an inquisitive mind made this look like a good relationship. Considering the time we were to spend together over the next 1,100 miles, and the work schedule that would develop, I was very pleased we drew ET from the pile.

"Applying our APT-gained information to the computer modeling gave us the truth."

ET came equipped with a 1.7 meter dish, a receiver, a computer, and 15 years' experience as a professional meteorologist. ET and I shared information on what was available from each other's services. From the ANIK E satellite, ET was able to pull all weather maps available from Environment Canada. We had regional radar summaries, computer models, cloud cover statistics, weather forecasts, observations from both private and public agencies, and custom-plotted solar insulation factors for the race route. I had all products from NAM/NMC, plus the polar orbitals. Just prior to the race, NOAA 9 was turned off for reasons unknown. NOAA 10 had been off a few months, due to course collision with NOAA 12. Of course, the Russians turned off MET 3-4, so we were left with three satellites for the duration. Marginal, but we could make it!

We compared time schedules for weather products, reviewed the daily schedule for the race and estimated our future locations for collection of products. We put together a plan for the next nine days and hoped for the best. I made a preliminary list of every NOAA and MET orbit during the race. I used Auto Map to roughly determine the long./lat. coordinates of locations along the route, and assigned reasonable time frames for our progress. This provided a list of possibilities, based on where we would be at any given time. The list was kept available for reference, but a second list was made of the required passes. This list was then integrated with my daily "activity schedule" and printed. The daily schedule was a list of activities I needed to perform, based on time and date. The day was spent checking off events as they occurred. Although near overhead orbital passes might be caught free-hand on the APT2CP, the longer passes which required tracking necessitated finding a suitable place to park Mondo, facing north, and determining our current position using GAPS. The exact coordinates were then entered into the tracking program.

The data ET was receiving would be used in conjunction with the images from the orbitals and additional charts from NAM/NMC. I was very pleased to hear from ET that the quality of the images I was gathering on the road were better than those available back at the office. As ET said, we know a front is going to move, we just don't know when, or how fast. Computer modeling will move the front based on many factors, all conjecture. We were able to view the front three times a day, and therefore knew exactly how fast, and in which direction, it was moving. Applying our APT-gained information to the computer modeling gave us the truth. We relied heavily on 72-hour predictions from HF sources, and reviewed the GOES images twice daily.

Any Good Boy Scout Is Well Prepared

I used the MultiFax demodulator and software for day-to-day use. As expected, the grid/mapping capabilities would come in handy. Reviewing the race course before leaving Kalamazoo, it became painfully obvious we could have some real "Where are we?" problems. The lack of geographic landmarks through the plains states coupled with the likelihood of fairly dense cloud cover would severely hinder our efforts. I took an hour or so and put together a "grid-map locator" database using every conceivable landmark that could be seen and identified from space.

Only two days into the race, we were cloud-covered! The team wanted to know "What's out there?" Reviewing a morning NOAA pass, I found two

landmarks for the map overlay. Would you believe the only landmarks I could find were the Great Salt Lake and the Door Peninsula of Wisconsin? Well, it worked! The map overlay allowed us to determine where in the clouds we were, and therefore to determine where and when our solar car could expect to find sunshine. This feature was used three times during the race, and was crucial to our success.

Another advantage we had was the extremely high quality images. We could capture the near overhead passes with the APT2CP, which is a story in itself. Briefly, I couldn't provide the clearance necessary for a complete antenna, so I used the roof of the car as a non-resonant reflector. The performance of the antenna was noticeably reduced, but I had been practicing and fine-tuning the entire system for the previous two months and knew the limitations. The APT-4X4RMX yagi coupled with the Yaesu AZ/EL rotor would allow us to reach out for the long passes. The 4X4 antenna provided incredible images, on passes as low as 9 maximum elevation; not bad for mobile! That meant we could get distant early morning passes to get an early look at the day, and look ahead to the west a long way on later passes. We could use passes not available to an omnidirectional antenna. This literally doubled the number of usable passes available to us. The directionality of the yagi was also a significant contributor to reduction of noise pickup from devices within Mondo.

Although I assume no credit for weather forecasting, we had all of the information needed, and ET was very skilled. We had no surprises; the weather happened just as predicted, when predicted. Over 4,500 miles were logged for Sunrayce '95, and another 1,500 miles were put on the equipment during preparation testing before the race. Everything worked well, with no problems.

Other Satellite Applications

I wasn't the only one using GPS on Sunrayce. Hughes was one of the major contributors for the event, and provided an interesting application of the telpath navigation system. The telpath system was developed for in-car use. A GPS receiver and a computerized map database and display will allow a driver to see where he is within a city. This can help guide the driver to the desired destination.

For Sunrayce, the application was to provide a GPS receiver for each vehicle team, connected to their cellular phone. The map display was the day's route, and the display(s) was (were) at the start/end of day and at the midday stop. You could approach a monitor and see the location of each car on the race course. This was a novel approach to provide the hordes of visitors a clue as to where their favorite car was.

Driving by the S-Meter

The first day was a short course, from Indianapolis to Terre Haute. After a glorious start at the War Memorial and Capitol building, with a rousing series of speeches and well-wishes from the Mayor and the Secretary of Transportation, the cars were off. We headed out of town toward Terre Haute. ET requested a chart from NAM in Norfolk.

Well, as expected, propagation was terrible, and by then it was about 1500 UTC. The morning propagation from NAM had shifted; we were somewhere between the short and long hops, if there were actually any hops at all. We were cruising down the highway, desperately seeking NAM on all frequencies programmed into memories on the HF rig. We didn't have time to stop; we had to get this one on the fly. I lit a cigar in frustration, while keeping my ear to the radio and one finger depressing the scan switch on the microphone. I noticed an 18-wheeler approaching in my side mirror. "Oh great!" I exclaimed. "Just what I need, the biggest shadow on the road and I have less than S-1 signal to begin with."

The rig slipped past me and as he started to pull back into the driving lane, the S-meter jumped. "Yes!" The perfect reflector for my antenna was now directly in front of me, and we were driving exactly opposite Norfolk. I asked Pam to check the map and see if this road would be straight for the next 25 miles. Upon confirmation that the road should be good, I began closing the distance between us and the large rear end of the trailer. I kept an eye on the S-meter, and sure enough, when we were about two wavelengths behind the rig, the S-meter jumped to about S-4. Good enough! I kept one eye on the S-meter, and one eye on the semi in front. I wanted to keep the signal as strong as possible, but even at 3 MHz, we were very close to a very large bumper! I believe Pam rested her eyes for the next half hour, and when I slowed down to back off from the trailer, she squinted into the back seat to view the monitor. "Well, you got it; I hope you're happy."

Amateur Spotters along the Way

From Indianapolis to Aurora, Colorado, teams of amateur radio operators provided spotting for the officials. Check points were set up along the route, and as each car passed, the time and car number were noted and passed

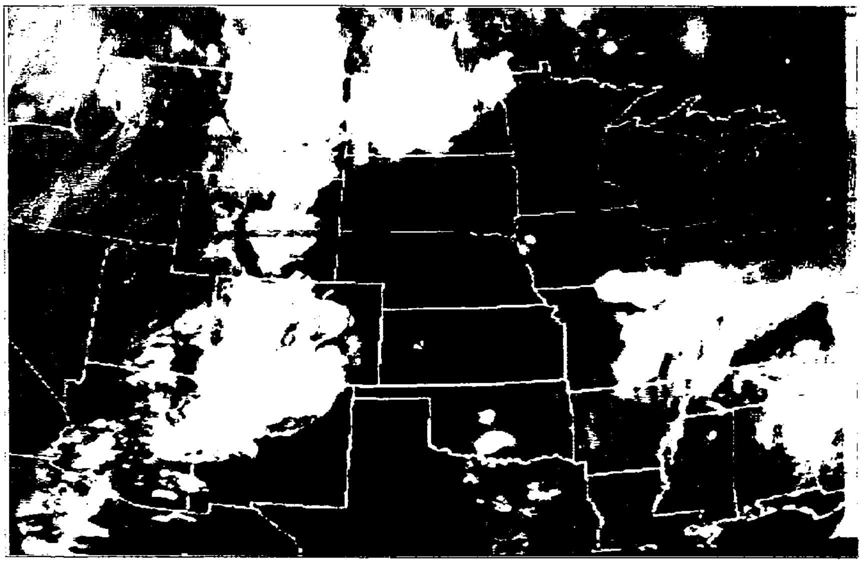

Photo F. Map overlay on NOAA image taken at Alton, IL. The overlay enabled us to determine the edge of the storm and hope for the rest of the day. The large front over the Rockies is beginning to move.

on. This was very beneficial in locating cars which might be suffering mechanical problems, and in keeping an overall eye on the progress.

Bennett Basore W5ZTN spearheaded this effort, as he did in '93. Bennett deserves some kind of sainthood award for his efforts and patience. Along the road we encountered every level of amateur, communication ability, and obstacle. Even though we frequently stretched the capabilities of local systems, and there seemed to be some deficiencies in preparation, every individual, club, and organization must be commended for their efforts. To achieve cross-country coverage during the week, many people took time off from work to be able to man the radios. I know there were many inconveniences faced by all involved, and the spotting locations were always less than where you would like to spend four or five hours!

Although Denver was not able to provide radio communication the last day of the race, the Denver area ATV group went all out and provided images from two camera locations to the end-of-race finish line. It was raining all day, and it was cold! Not only a miserable end for a solar event, but nothing short of hazard duty for the camera operators who stood by their cameras, providing continuously framed and focused images as cars approached the finish line.

QRX While I Reload

What's next? Hopefully by the time you read this, I'll be preparing to cruise across the Outback of Australia with the World Solar Challenge. The WSC is the other big event in solar-powered vehicles. This event is more demanding than Sunrayce, as the course is much longer and almost no one feels as if they are "at home." At the time of writing this article, I have a tentative invitation. For now, I am preparing, learning as much about the land down under as I can, and dreaming of tracking satellites upside down.

Souping Up a Surplus Field Strength Meter

Increase the sensitivity of your ME-61/GRC field strength meter.

Phil Salas AD5X
1517 Creekside Drive
Richardson TX 75081

An interesting piece of surplus test equipment that has been showing up lately is the ME-61/GRC field strength meter. I've seen them at both Dayton and the Dallas HAMCOM. These ME-61/GRC field strength meters have all been in sealed cardboard cartons (i.e. they are all unused). Prices seem to range from $15 to $25.

What is the ME-61/GRC? It is a tunable field strength meter "for use with such tactical radio systems as Radio Sets AN/GRC-9, AN/GRC-87, and AN/VRC-34," whatever those are. The instruction manual that came with my unit was dated 1966, so these are probably Vietnam War era products. It is interesting to read the instruction book section titled "Demolition to prevent enemy use" which, incidentally, comes right after the alignment and troubleshooting section.

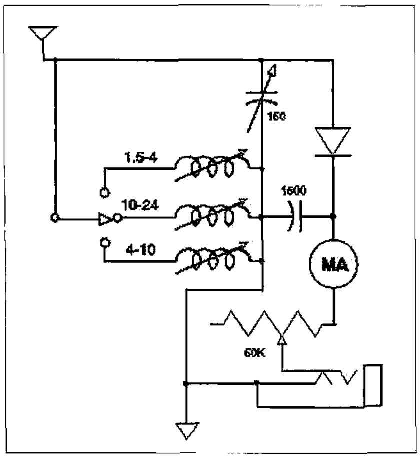

Fig. 1. Original circuit.

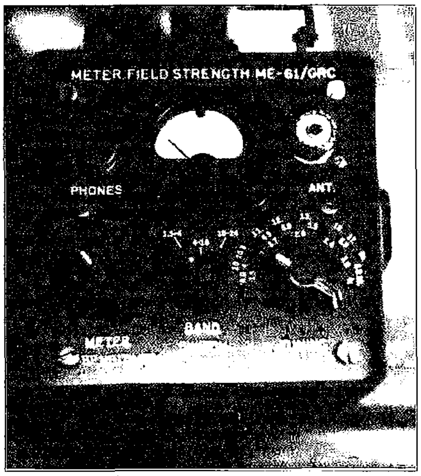

Photo A. *The ME-61/GRC field strength meter with the SO-239 connector.*

ME-61 FSM Description

The ME-61 FSM comes in a very nice military green watertight enclosure which includes a telescoping whip antenna and covers 1.5 to 24 MHz in three calibrated ranges: 1.5–4 MHz, 4–10 MHz, and 10–24 MHz (160 through 15 meters). As shown in Figure 1, the schematic, the ME-61 FSM covers these three ranges by switching in different inductors. The variable capacitor is common to all three ranges. A second bandswitch position (not shown on the schematic) also shorts out the unused inductors so that there is no mutual coupling between the used and unused inductors. The resulting parallel-tuned circuit feeds a simple diode detector and then a 1 milliamp meter through a 50k ohm variable pot. Headphones can be plugged into the phone jack for detecting AM signals. The ME-61 FSM works well; however, it is not that sensitive—due primarily to the 1 milliamp meter that the detector circuitry has to drive.

Modifications

There are typically two problems with the ME-61 FSM: The internal pull-up telescoping antenna corrodes easily, and the lack of sensitivity, as mentioned earlier.

My ME-61 FSM was similar to others that I had seen in that its antenna was corroded. I addressed this problem by completely removing the antenna and mount from the front panel. The hole that remains is just slightly larger than that required by an SO-239 UHF connector. Therefore, I centered an SO-239 on the hole and carefully marked locations for two mounting screws. After drilling #4 holes in the front panel, I mounted the SO-239 from the inside of the front panel. This looks good (see Photo A). For the antenna, I used a Radio

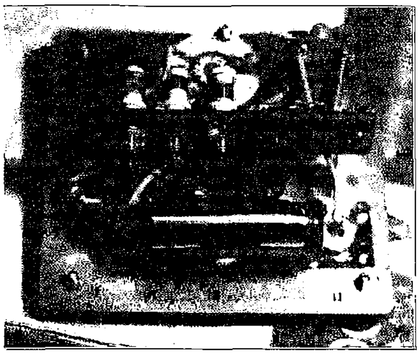

Photo B. *The inside of the ME-61, showing the battery hot-glued to the meter.*

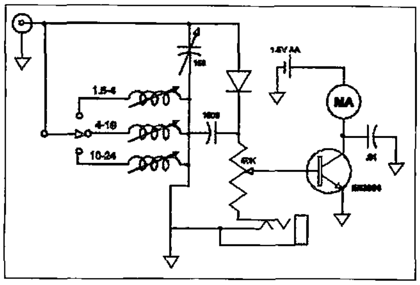

Fig. 2. New circuit.

Shack 270-1409 six-section cordless phone replacement antenna ($3.49) soldered to a banana plug (RS 274-721). The banana plug plugs into the center hole of the SO-239, and the collapsed antenna easily fits inside the cover of the box.

Now for the sensitivity improvement. As you can see from Figure 2, I simply rewired the metering circuitry and added a 2N3904 NPN transistor as a current amplifier (almost any NPN transistor can be used). I also changed the detector diode to a 1N34 germanium diode (RS 276-1123). The 1.5V AA battery is mounted in a plastic battery holder (RS 270-401) which has been hot-glued to the meter (see Photo B). You'll note that there is no on/off switch. With no signal input, the transistor can't turn on and therefore no current is drawn from the battery.

Results

The sensitivity improvement is significant. Before the modification, I could get no more than a half-scale reading at maximum sensitivity when I was located approximately 100 feet from my mobile antenna, running 100 watts output power. After the modification, I can get a full-scale meter reading at 100 feet with only 10 watts of output power, with less than full sensitivity!

Conclusion

If you would like a frequency-selective field strength meter, keep your eye out for the ME-61. The simple modifications described here can really turn the ME-61 into a valuable piece of test equipment. Other modifications can enhance the ME-61 even further. As an example, you might want to turn the 1.5–4 MHz range into a 15-40 MHz range if the higher frequencies are more interesting to you. Also, it is better to have an RF preamp ahead of the detector than a DC amplifier after it. You could replace the 50k pot with a combination 50k pot and switch for powering the RF preamp. Or maybe you could use the phone jack hole for something since most folks don't use AM detectors anymore. Experiment and have fun!

Microwaving on Monument Peak

The story behind our cover photo.

C.L. Houghton WB6IGP
San Diego Microwave Group
6345 Badger Lake Ave.
San Diego CA 92119

I took the cover photo on top of Monument Peak (DM12SV) in the Laguna Mountain area of Southern California. This location is about 50 miles east of San Diego at an elevation of 6,300 feet. This operation was part of the ARRL 10 GHz contest in September 1991. 10 GHz contacts were to be attempted between the San Diego Microwave Group and a group of amateurs operating from Mount Union (DM34TK) at a 7,700-foot location near Montezuma Castle National Monument in central Arizona.

The photograph shows a portion of Monument Peak—real billy-goat territory—and our stations on top of a small pile of rocks, to which the two stations were anchored. Several bungie cords and cables were used to tie the equipment firmly to the rocks to keep them upright in the heavy winds. Kerry N6IZW is pictured on part of the rocks (our chair) just below his dish antenna and 10 GHz equipment during this memorable contact. The tower to the right is part of several commercial installations sharing this mountaintop location.

Our microwave shot is not a record distance, but consider that this path was obscured by several other mountains, making this attempt a tough challenge. The plan agreed upon was for the Arizona station to transmit during every even 10-minute period, and our station to transmit on odd 10-minute segments in case the lower frequency liaison could not be established. Ultimately, 2 meter SSB contacts were made. After some 30 minutes of antenna orientation and frequency scanning, both Kerry N6IZW and Chuck WB6IGP made contact with Dave KY7B within a minute of each other.

Signals were not strong initially but did increase to allow operation from all of our group members that day. Part of the reason that Kerry and I made contact first was that we both use similar equipment and 10 watts of power feeding a 30-inch dish antenna. Consider that our 10 watts of power and KY7B's 28 watts both feed high gain microwave dish antennas (34 dB gain), the product of which produces quite a high ERP power level. This gave us quite an edge when signals were marginal. As time elapsed, signals increased to S-2 for short periods of time.

Ed W6OYJ, John WB6BKR, and Jerry WA6VLF made contacts with two of the stations, operating with only 100 milliwatts. Signal conditions fluctuated, rapidly producing severe Doppler frequency shifts on SSB voice. Voice could be best described as a good Halloween ghost voice imitation due to multiple reflections and cloud scatter. We speculate this was partly due to reported heavy rain near our midpath calculations. Signals peaked quite high for a few moments and we suspect we were reflecting off aircraft flying through the same area. The biggest regret of this whole contact was that we had all forgotten our tape recorders for capturing the cloud scatter audio contact, useful for future brag sessions. 73

***Photo A.** Microwave operation in the San Diego mountains at an elevation of 6,000 feet above sea level. Making contact over the distant mountains required antenna alignment to be accurate within 1 or 2 degrees on the compass. Just beyond this vantage point, the mountain drops off 5,000 feet to the desert floor.*

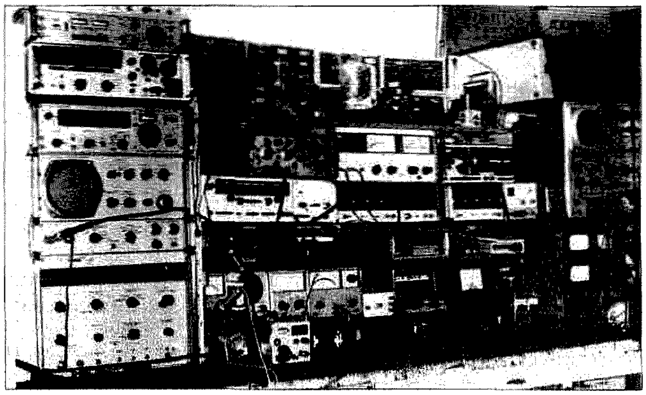

***Photo B.** The test workbench at WB6IGP. It's equipped with spectrum analyzers, sweepers, signal generators, vector voltmeters, scope and plain old VOM and solderings— a lot of junk that the power company would be proud of if I turned it all on at one time! This is where most projects get the final test.*

A Mobile Power Panel

Protect your vehicle and your rig.

Tony Marchese, N2YMW
35 Shannon Crescent
Spencerport NY 14559-9758

I recently obtained a 2 meter radio for my car. After consulting several sources, I was convinced that a direct connection to the battery was the best method to obtain power for the radio. This, however, presented me with an interesting dilemma. I was thrilled to have the radio but hesitant to connect equipment directly to the battery for fear of causing costly damage to the vehicle's electrical system. What I needed was a method to protect both the vehicle's electrical system and the radio equipment from subsequent power problems.

The power panel described in this article was designed to protect the vehicle and radio equipment. I have also used this opportunity to standardize the connectors on my own equipment, including the power panel and a 13.5 VDC supply. This simplifies movement of my equipment between various vehicles and my home QTH.

The power panel incorporates two levels of overload protection. The primary source of protection is provided by a set of inline, 15 amp, fast-acting fuses that are located close to the positive and negative battery terminals. These primary fuses guard against potential shorts from cable chafing and abrasions inside the engine compartment. A secondary level of overload protection is provided by a set of 7 amp fast-acting fuses which protect against electrical overload from high power equipment and potential cabling problems within the vehicle's cab. The secondary fuses are physically located on the exterior of the main power panel to allow quick access and easy replacement.

The almost inevitable need for noise suppression was satisfied by incorporating a filter network into the unit, thereby avoiding the unsightly rat's nest of wires which is sure to result if independent components are installed later. The power panel also incorporates an analog meter to monitor the current passing through the output connector. The meter is not essential for the system's operation and may be omitted if desired. I have, however, found this option to be particularly useful for monitoring the nominal current drawn from the battery during various operating conditions.

The power panel schematic is shown in Fig. 1. The 30 µH filter choke was constructed by winding 12 turns of 16 AWG insulated wire onto a T-200-1 powdered iron core. The 50 µA, 2.56k ohm analog meter movement utilizes the filter choke's 0.012 ohm winding resistance as a current shunt. This increases the full scale meter reading to approximately 10 amperes. The meter face has been highlighted in red from the 7 ampere mark to allow quick identification of the secondary fuse meltdown point.

The power panel also includes a relay which disconnects power when the ignition is off. The relay is activated by a separate power connection to an "Accessory" slot on the vehicle's fuse block. This prevents the radio from draining the battery if the unit is accidentally left on.

Construction of the power panel is fairly easy as no circuit board or special wiring techniques are required. All connections were made on a single barrier strip mounted inside the metal cabinet. I did, however, solder a 20 AWG wire directly to each end of the choke to prevent inadvertent disconnection as removal of the shunt resistance would allow the supply current to pass through and destroy the panel meter. Connect the opposite end of each of the smaller wires to the meter movement.

I produced the current version of the power panel in less than two hours. An additional hour was required to install the unit in my car. The time invested was well worth the effort as I can swap radios in under five minutes and not compromise my vehicle's electrical system.

Parts List

- 50 µA, 2,560 ohm analog meter movement (Mouser #564-72T-1050 or equivalent)
- T-200-1 powdered iron core (Amidon Part #T-200-1)
- 2200 µF, 25V electrolytic capacitor
- (2) 7 ampere, fast-acting fuses with panel mount holders
- (2) 15 ampere, fast-acting fuses with inline holders
- 36" section of 16 AWG insulated wire
- 12 AWG THHN or equivalent wire (enough to reach from battery to power panel)
- DPDT switch with contacts rated 10 amps (minimum)
- 12V lamp with holder
- Panel-mount, female connector, 10 amp contact rating (minimum) and mating male plug
- 6-position or larger barrier strip
- 6-10" of small gauge wire
- Metal cabinet
- Misc. hardware
- 12V SPST relay with N.O. contact (Mouser #526-R22-1D16-12 or equivalent)

Mouser Electronics: (800) 346-6873.
Amidon Associates: 12033 Otsego Street, North Hollywood, CA 91607.

Do You Remember?

Glen E. Zook W5UOJ
410 Lawndale Drive
Richardson TX 75080

Every once-in-a while, many amateurs like to take time to reflect, time to remember. About 20 years ago I wrote a similar article which Wayne published in *73* which met with a favorable response from the readers. This one has been updated somewhat, but is still aimed at the over-25 crowd. Over 25 years as an amateur, that is, the QCWA crowd. However, newer amateurs might just get a kick out of trying to make sense of the following list. But, if you have to ask any questions, then you really don't remember.

So, without further ado:

Do You Remember?

The "Sixer," "Twoer," and "Tener"?

ARC5s?

The "Dream Receiver" (the one I owned was more like a "nightmare"!)?

The BC779?

The "My QTH" QSL cards?

Basic Packet Modem

Greg Cerenzia N3PRT
4 Leesa Court
Lexington Park MD 20653

Want to get on packet for a minimum investment? Want to try packet without the cost of buying a TNC? Or would you like to operate portable packet without taking your TNC with you? Then this is for you! This project is an easy-to-build Bell 202 1200 baud packet modem that is powered from the computer's serial port and requires a minimum of parts. While it is not a TNC by itself, the modem and a software TNC program running on your computer can perform many of the same functions as a TNC and will get you up on packet for a minimal investment. (Note: This project is available in kit form from LDG Electronics. See the Parts List for ordering information.)

When I first decided to build my own packet modem I was surprised that not much information was available. After doing lots of research, reviewing technical notes from the modem chip manµFacturer, and experimenting, I found that the modem chip could work with only a few added components. I have used this design for over a year as of this writing and it works well. Members of our local club have also built this project and are happy with the results.

Uses

This modem is designed to work with the serial port of most IBM-compatible computers. A software TNC program is required for operation and most BBSs have shareware TNC programs available for downloading. Known compatible programs are Baycom and SofTNC from j•Com. (Although SofTNC works well when configured for com 1, I have not yet been able to get it to work on com 2.) I have seen numerous other software programs and drivers on the Internet for this type of modem that allow TCP/IP use, games, and Windows-compatible programs, etc. With the simplicity of this setup I am sure that others will continue to be developed.

Circuit Analysis and Operation

The software TNC program is the heart of this setup. Most of these programs have the same major features in common. They provide a memory-resident AX.25 packet protocol, a user terminal interface to send and receive from, and a means to access the computer's serial or parallel port. It should be noted that most software TNC programs do not use the standard RS-232 pins of the serial port. They use the DTR line for TXD, the CTS line for RXD and the RTS line for PTT. Therefore, these programs were written specifically for this type of modem.

Photo A. The author's Basic Packet Modem setup with radio, cables and laptop.

Refer to the schematic, Fig. 1. Power is supplied to the modem from the computer by the TXD, DTR and RTS lines of the serial port. Diodes D1, D2 and D3 allow the positive voltages to reach the voltage regulator VR1 to power the circuit, but do not allow these lines to interfere with one another. Most software TNC programs will raise the TXD line of the serial port high constantly while the program is running. They will also keep the DTR line high while receiving. When the RTS line goes high to key the radio, the DTR line will send data by toggling high and low. The high TXD, high RTS when keyed, and high pulses of the DTR line provide power to VR1, which supplies the circuit with the required 5 volts. Capacitors C1 and C2 provide filtering and stability of the regulator and the output voltage.

IC2 is a 74HC04 CMOS hex inverter. It draws less current than a standard 7404, which is why it was chosen for this circuit. It performs the dual functions of inverting the appropriate signals and serving as a pseudo RS-232 to TTL line converter.

To key the radio, the software raises the RTS line of the serial port high. Since almost all radios require their PTT line to be pulled low to key the radio, this high level must be converted to a low level or ground closure. The high RTS goes to pin 3 of the inverter and is converted to a low output on pin 4,

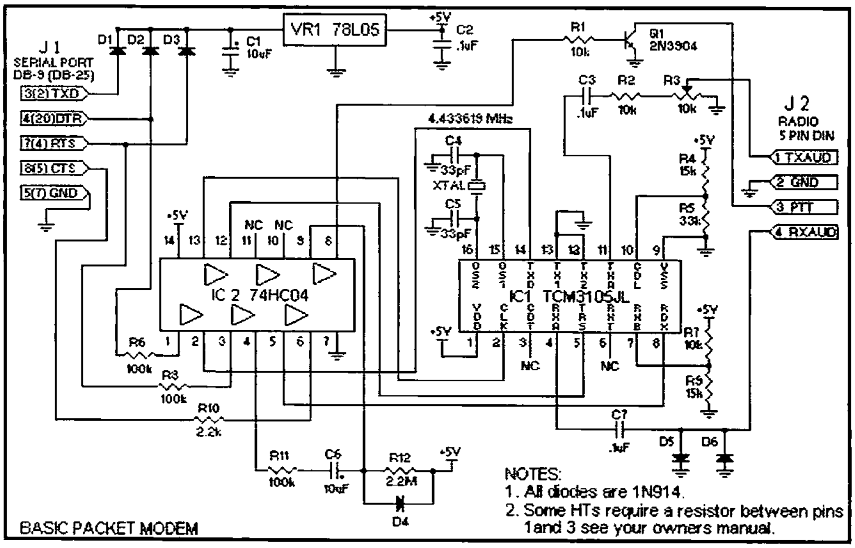

Fig. 1. Schematic for the modem.

where it is routed to a time-out circuit and to pin 9 of the inverter. The low on pin 9 is converted to a high on pin 8 that turns on Q1. When Q1 turns on, it provides the low or ground closure for the PTT of the radio.

The keying time-out circuit is provided in case the software hangs up or you run another program that raises the RTS line high. It prevents your radio from either causing interference on the channel or burning up! The circuit is comprised of capacitor C6, resistor R12, and diode D4. As soon as the software raises the RTS line high, pin 4 of the inverter goes low. This allows C6 to start charging through R12. After C6 charges to about one time constant (approximately 20 seconds), the voltage "seen" at pin 9 will be high enough to cause pin 8 to go low, thus unkeying the radio. C6 will continue to charge until it reaches a charge close to the supply voltage. D4 is provided to keep pin 9 from seeing the 5V supply to the timer circuit. When the RTS line goes low, C6 will discharge and the timing circuit will begin again on the next key.

IC1 the TCM3105JL chip is the main component of the circuit. It is a single chip asynchronous Frequency Shift Keying (FSK) voice band modem that can be jumper selected to the Bell 202 modem standards. A pin-by-pin description of the modem chip follows:

Pin 2 (CLK) is a clock output. It is sent to the hex inverter and then fed back to pin 5 (TRS) of the modem chip to provide an inverted clock signal for Bell 202 mode.

Pin 3 (CDT) provides a carrier detect output. It isn't used on most serial port software TNC programs, but can be hooked up for certain applications that may require it.

Pin 4 (RXA) is the receive audio input. C7 is an AC coupling capacitor and D5 and D6 form a clipper circuit to limit the audio input to the modem chip.

Pin 7 (RXB) is the receive bias. The bias voltage tells the modem's internal comparator at what level to slice the DC variations fed to it from the internal multivibrator demodulator.

Pin 8 (RXD) is the comparator's output. This is the receive data that is inverted and then fed to the computer's CTS port.

Pin 10 (CDL) has a level set by R4 and R5 for the pin 3 (CDT) output.

Pin 11 (TXA) output of the modem. It is AC coupled by C3 and its' level is set by R2 and R3.

Pins 12 (TX1) and 13 (TX2) are strapped together and tied low for the Bell 202 mode.

Pin 14 (TXD) transmit data from the computer's serial port is inverted and then sent to modem on this pin.

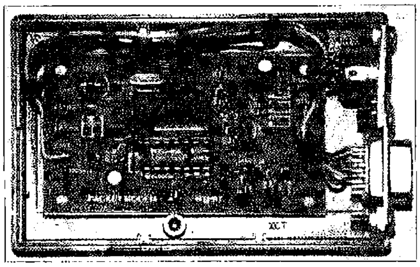

Photo B. The completed circuit board installed in case.

Pins 15 (OS1) and 16 (OS2) are the connections for the 4.433619 MHz crystal and C4 and C5 capacitors which set the frequency for the on-chip oscillator.

Construction

Construction is pretty straightforward. See the Parts List and refer to the schematic diagram (Fig. 1) for component interconnections. When installing the parts, observe proper orientation of the diodes and capacitors. Note that the miniature voltage regulator looks identical to the transistor, so check them before you install. To prevent damage to the ICs, use sockets and install them last. You can construct this circuit on perf board. I have built one this way, but it was pretty messy, so unless you are a skilled perf board builder the printed circuit board is recommended. See Fig. 6 for the circuit board layout.

Enclosure

The enclosure listed in the Parts List is small and has a removable battery cover to accesses the potentiometer R3 level adjustment. If you chose to use this enclosure you will have to remove the battery compartment divider by carefully cutting it out with a hobby knife or rotary cutter. Do not try to bend and break it out, because you will probably destroy the enclosure. Use the front panel and carefully drill and file to mount the 5-pin DIN chassis mount connector and the 9-pin D-SUB female with 4-40 screws and hex nuts. It may be necessary to file the corner off the 9-pin D-SUB connector for both of these to fit. Do not overtighten the screws or you will damage the front panel. A sturdier front panel can be made from aluminum cut to the same size as the plastic panel.

Use short runs of wire and connect the circuit board to the appropriate pins of the connectors on your enclosure. Refer to Fig. 1, 2, and 3.

CIRCUIT BOARD TO J1 SERIAL PORT CONNECTIONS

CIRCUIT BOARD	FUNCTION*	J1 CONNECTOR, DB-9	OR DB-25
TXD 3	POWER	3	2
DTR 4	TRANSMIT DIGITAL DATA/POWER	4	20
RTS 7	PUSH-TO-TALK/POWER	7	4
CTS 8	RECEIVE DIGITAL DATA	8	5
GND 5	GROUND	5	7

Note: The functions listed are referenced for this modem. They are not standard RS-232 functions.

Fig. 2. Pinouts from the circuit to the enclosure's J1 data connector.

CIRCUIT BOARD TO J2 RADIO CONNECTOR

CIRCUIT BOARD	FUNCTION	J2 5-PIN DIN
TXAUD 1	Transmit Audio	1
GND 2	Ground	2
PTT 3	Push-to-Taik	3
RXAUD 4	Receive Audio	4

Look at your 5-PIN DIN connector numbering carefully; it is not numbered in sequence. This view, looking at the solder side of the chassis connector, should help:

TXAUD-1 3-PTT
RXAUD-4 5-N/C
2-GND
Modem Chassis Connector Solder Side

Fig. 3. Pinouts from the circuit board to the enclosure's J2 radio connector.

COMPUTER FEMALE CONN.		FUNCTION*	MODEM MALE CONN.	
DB-9 OR DB-25			DB-9 OR DB-25	
3	2	POWER	3	2
4	20	TRANSMIT DIGITAL DATA/POWER	4	20
7	4	PUSH-TO-TALK/POWER	7	4
8	5	RECEIVE DIGITAL DATA	8	5
5	7	GROUND	5	7

Note: The functions listed are referenced for this modem. They are not standard RS-232 functions.

Fig. 4. Pinouts from the computer to the modem interface cable.

5-PIN DIN		FUNCTION	RADIO CONNECTOR
TXAUD	1	Transmit Audio	A/R *
GND	2	Ground	A/R
PTT	3	Push-to-Talk	A/R
RXAUD	4	Receive Audio	A/R

Look at your 5-PIN DIN connector numbering carefully; it is not numbered in sequence. This view, looking at the solder side of the plug connector, should help:

3-PTT 1-TXAUD
5-N/C 4-RXAUD
2-GND
Plug Connector Solder Solder Side

Note: Refer to you owners manual for the pin-out of your radio connector.

Fig. 5. Pinouts from the modem to the radio cable.

Computer Data Interface Cable

Some computer data cables are on the expensive side and since you have already built your own modem; why not build your own data cable? A standard data cable will work, but for this interface five lines are all that is required. Refer to Fig. 4 for the pinout. If you purchased the bulk data cable in the Parts List, the shield counts as the fifth conductor (GND). The shield should be twisted together and have heat shrink put over it to form a wire. You may also want to put some heat shrink over the data cable where it enters the backshell. This will provide firmer clamping once the backshell is assembled. Note that this cable is for this modem only. It won't work with a landline-type modem, because some of the other lines required are not used in this interface. You can build a cable to go from DB-9 to DB-9 or DB-25 if your computer has a DB-25 serial port.

Radio Interface Cables

The stereo cable for most audio systems and VCRs makes a great interface cable for handhelds. It gives you two separate cables for each of the radio connectors to attach, but is still joined together as one cable. Simply cut the phono plugs off and cut the cable to the desired length. You may want to put a small piece of heat shrink over the cable to keep it from "zipping" apart. Then attach the radio mini-plugs. Refer to your owner's manual for the proper pinout of the radio plugs and to see if a keying resistor is required for your handheld. Handhelds that have no separate push-to-talk line incorporate it into the transmit audio line of a remote microphone. This transmit audio line has a DC logic high that is usually "blocked" by a capacitor installed in the mike. In the modem circuit capacitor C3 performs this "blocking" function. An AC audio signal can coexist on this same line without the DC signal interfering. When the PTT line of the modem goes low the keying resistor causes a voltage drop from the DC high, thus making the radio key without shorting the audio signal to ground. If your radio needs this resistor it can be easily installed inside the backshell of the 5-pin DIN plug between the TXAUD line and the PTT line. Usually a 2.2k or 3.9k resistor is used, depending on the make of the radio, so check your owner's manual for details.

For mobile rigs, the same cable type that was used for the serial port interface cable can be used. You may want to add some heat shrink where the cable enters the backshell of the radio connector to provide better holding when the clamp is tightened down. Refer to your owner's manual for the proper pinout of the radio connector. Most mobile rigs can have the PTT line hooked up directly without a keying resistor. The pinout for the 5-pin DIN mating plug for the chassis mount plug is shown in Fig. 5.

Setup and Adjustments

If you are new to packet now is a good time to invite someone with packet experience to help you. They will be familiar with the various packet settings in the configuration file of your software, and may be able to help if you have any other problems. If no such person is available, I'll try to give you some brief pointers to get started. Read the documentation for your packet program thoroughly. Set up the configuration file for your callsign, COM port and any other custom information for your computer, etc. Turn off your computer (most computer manµFacturers recommend doing this before hooking up peripherals to ports). Hook up your radio and computer to the modem then turn on the computer and run the TNC program. Unsquelch your radio and adjust the volume just to the point where the RX indicator of your program comes on or flashes. It is not necessary to increase the volume beyond this point.

If you are on an active packet frequency you should now be able to monitor decoded packets on the screen. If not, check your software setup and manual. Read the instructions for your software on how to connect to another station. Hopefully everything is working fine. If not, here are some troubleshooting tips.

Troubleshooting

If your modem is not working properly, don't panic. It is usually something simple. Listed below are some of the common problems, solutions and troubleshooting tips. All of these tests require that your modem be connected to the computer, with the software TNC program running. If, after following these steps, you still have no luck, use a multimeter, the schematic shown in Fig. 1, and the theory of operation section to track down your problem.

Using a multimeter, check for continuity and shorts in the interface cables to

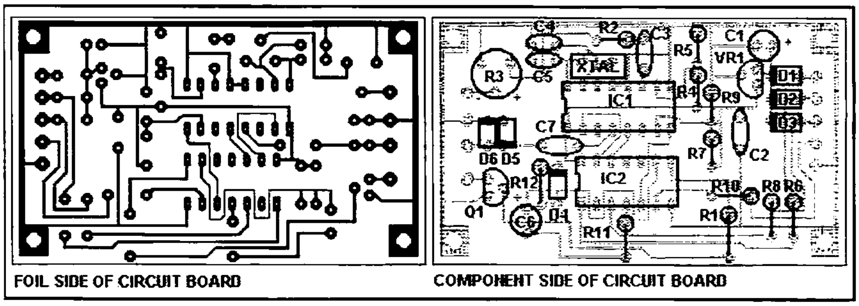

Fig. 6. Circuit board and component layout.

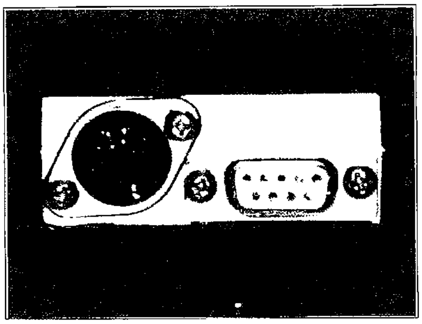

Photo C. The front panel showing the 5 Pin DIN radio connector and the DB-9 computer connector.

the radio and computer and wiring to the connectors and circuit board of the modem.

Make voltage readings on IC1 pins 1 and 9, IC2 pins 14 and 7. You should have a voltage very close to 5V. If not, check for a 5V output on VR1 at the point where it connects to C2.

If your radio keys up and you are using a handheld with a keying resistor, try reducing R3 until it unkeys. If you still cannot get the radio to unkey and are sure everything else is OK, R2 may have to be replaced with a lower value resistor.

If you are not receiving packets, first make sure that the software TNC program you are running will allow you to monitor what is happening on an active channel and that you are using the proper serial port. Then find the status indicator of your program. When your S-meter or busy indicator shows activity on your radio the RX or RECV indicator of your program should light. If not, try unsquelching your radio . White noise from the radio will cause the indicator to light if the volume level is high enough. It should not be necessary to turn the volume above halfway. If you see no receive indication, check for power to the modem.

If others are having trouble decoding your packets try the R3 adjustment that affects the audio output level. In testing, over-deviation was almost impossible with the radios tested. However, distortion was not. Too high a setting will cause the audio to be distorted and the receiving station may have some problems decoding your packets. If you see too many REJs (REJECT), try lowering the output slightly. Usually, about midway works fine. Also, try increasing your transmit delay time in your TNC software program.

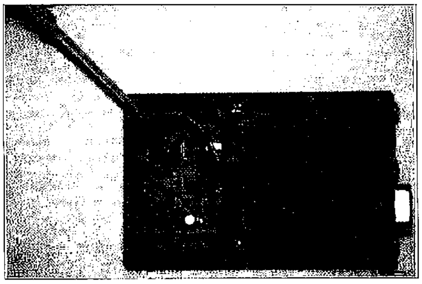

Photo D. The bottom cover of the case removed to get to the audio level adjustment.

If your radio is not keying and it is a handheld, refer to your owner's manual to see if it needs a keying resistor. Radios that use this resistor will not key properly without it. For radios using a separate PTT, disconnect the cable from the radio and connect an ohmmeter between the PTT line and GND. When the program transmits, you should see close to 0 ohms. Also, check to see that Q1's emitter is grounded to the radios' ground when the cable is hooked-up, and that the base of Q1 is going high when the program transmits. If not, check for power to IC2. If that is OK, see if pin 3 goes high when the program transmits. If not, either the program is set up for the wrong serial port or there is a problem with the serial port.

A quick check to see if your modem is active and transmitting packets can be done by unhooking the connector(s) from the radio and hooking headphones with some jumper clips to the TXAUD and GND lines on the radio connector(s). You should hear a low-level high-pitched continuous tone. When you send a transmission such as a connect request, a familiar packet burst sound should be heard momentarily, then the continuous tone will return. If you obtained these results, the modem is on and is transmitting data.

If your setup is working but acting erratically or the computer locks up, etc., RF is probably getting back into the computer or modem. The effect of RF appears as your computer monitor's picture jumping with each transmission relative to the power level you're operating at and the location of the antenna. The radio may also stay keyed after the first transmission or cycle back and forth. Usually it will help if you remote your antenna away from the packet setup or reduce power. For handhelds, use an antenna extension cable for mobile use with a rubber duck antenna or an outdoor antenna that can be located away from your station. Computers and monitors can generate a lot of noise. This may get into your receiver and be strong enough to keep your radio unsqelched. Again, moving

Photo E. The Basic Packet Modem is very portable and requires no external power.

your antenna or moving the location of the radio or cables should solve the problem. Some of the later versions of TNC software programs have a carrier command that can be set up for unsquelched operations. I have used this with much success.

Tips for 10 Meter Operation

Packet on 10 meters can be used between 28.0 and 28.3 MHz sideband. You can usually find packet stations on the lower sideband. Check your repeater directory for listings of 10 meter packet BBSs. Running sideband packet is a little different from 2 meter. Tuning is a little more critical, but once you get it dialed in you should have no problem. Also, if you are working DX packet stations, try increasing your retry count. It sometimes takes a little longer if the band is fading back and forth. It is possible to run unsqelched on sideband due to the lower receiver noise on sideband. First, set the volume so that the receive indicator of your software just comes on. Then back it off some just till the indicator goes out. When packets come in, the audio level is higher than the noise level of the receiver, and the software TNC program will go to receive mode and decode the packets. When the band is open strong, this works great. If the band is a little weak and fading in and out, you may have to "work" the volume control of the radio some. Using squelch on sideband will require the sending station to use a much longer transmit delay time. This longer delay time will send an audio preamble before any data is sent. Since audio is required for the squelch of a sideband radio to break, the audio preamble will first break your squelch. After the preset delay time, the data will be sent. If you are going to do lots of 10 meter packet, I highly recommend a software TNC program that has the carrier command for running open squelch.

Conclusion

I hope you have as much fun with this project as I did. I also hope that it has taken some of the mysteries out of packet and encouraged you to

experiment on your own. By putting the "brains" in the computer, programmers can come up with limitless options and upgrades that we can all afford. 73

LETTERS
Continued from page 6

I was an avionics officer in a special operations unit. I am an Air Force Reserve colonel today, attached to one of the alphabet agencies. Along the way I earned a B.A., B.S.E.E., M.B.A., and finally a Juris Doctor degree. The law practice supports my Air Force Reserve activities and pays for the DC-to-light ham gear. Thanks for the inspiration along the way!

Now for the important part. I just completed teaching three classes of sixth-graders a little about ham radio, shortwave listening, and opportunities in electronics as a career. I also donated $200 in "Now You're Talking" books to the school library and arranged classes with the local club. I also have given two subscriptions to your magazine to kids. My son, Barry KE4PUD (Passed Up Dad), earned his Novice license at age 9 and upgraded to Tech Plus at age 10. He is now 11 and working on the General.

If possible, please publish this little story as an incentive for some other aging Baby Boomers to get off their rears and invest some time and money in the future. Get the kids interested in electronics and engineering. If we do not help to mold the next generation there will be no amateur radio and a lack of engineers and technicians in the future. Please continue publishing and leading.

Sorry about 6-Up, *but it was a 1965 victim of the state employment police who stopped me from using high school kids for 50¢ an hour after school to address and mail the little magazine unless I paid them at least the minimum wage. The kids were happy to make some money and learn about publishing, but the employment department wouldn't let them do it, so I had to give it up. Hey, keep up the work with the kids, that's fantastic... Wayne)*

Jeff Olstad, BC. In response to your "Whadaya Read?" in the September issue, I am a flat beginner. I don't have my first license yet. I bought this issue to try and learn more about ham radio in general and more specifically antennas. It is my second issue of the magazine. When I read my first copy I thought if this magazine's circulation is good they would not listen to any advice from me, but seeing as you asked, I thought I would try to explain what I think. It is pretty obvious to me why your circulation is suffering. You insult the people who should be the bulk of your readers in many articles: the licensed operators. For beginners like myself you use so many abbreviations and make so many references to things you don't explain. Without a comprehensive reference library it's unreadable. So who is left that has any use for *73?*

(Thanks Jeff, sort of. First, you should be collecting 73 *magazine issues so you'll have a valuable encyclopedia of ham information that you're going to need later on, after you've come up to speed. Get out to hamfests and collect as many back issues as you can find. They're solid gold when you want to get started with RTTY, packet, SSTV, and so on. Second, the magazine's circulation isn't suffering, it's doing fine. I just want it to do even better. Third, what's all this about insulting people? Anybody else have a problem with that? Sure, I'm on your case about losing weight, stopping smoking, and not wasting your time with baloney like ball games and sitcoms when you could be reading and educating yourself...there being a known correlation between education and success. Or getting more involved with hamming and having a ball while you are learning. But I wasn't aware I, or any of our columnists, have been insulting about it .. Wayne)*

UHF/VHF Home-Brew Measuring Gadgets

Accurate, easy, satisfying.

John C. Reed W6IOJ
770 La Buena Tierra
Santa Barbara CA 93111

Take UHF power measurements? No problem. I simply place a diode across the 50-ohm line and the power will be

$$\frac{E^2}{R}$$

—and don't forget that the diode is a peak-reading device. Then I multiply the peak by 0.707 to bring it down to the RMS value. This means I'm assuming a sine wave input. Do I really have a sine wave?

Another thing: Diodes have lead-length inductance and junction capacitance. I wonder what that's doing to my load line? And speaking of the diode, everyone knows a diode is linear except at the lower levels. I wonder at what level this nonlinearity starts, and what the characteristics are? Also, there must be a diode rolloff. Where does that start?

These are the kinds of questions that come up when you measure RF power using a diode detector. The following article describes simple methods that address such considerations, and the hardware you can build to make accurate measurements.

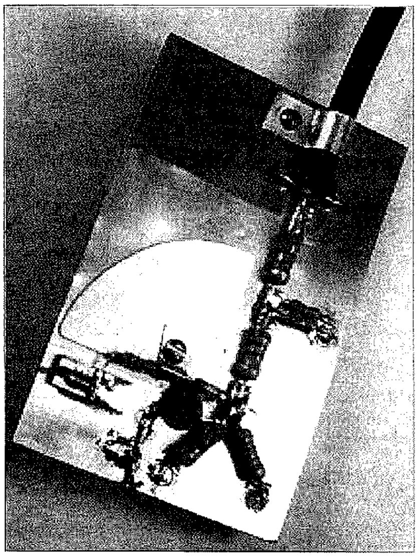

***Photo A.** The dummy-load/detector.*

This hardware includes a dummy-load/detector assembly (see Photo A) permitting 0.2 mW to 5 watts power measurements down to 70 cm, and a separate 10 dB attenuator (see Photo B) that increases this capability to 50 watts. Also included is a very simple thermal-type power measuring device for calibrating the peak reading diode assembly versus RMS input power. All parts for building these assemblies are available at Radio Shack®.

Dummy-Load/Detector

See Fig. 1. Two 100-ohm, 1/2-watt resistors in parallel connected across a 50-ohm cable with near zero lead lengths will be very close to a 50-ohm termination with the SWR less than 1.1:1.

However, adding the diode introduces capacitive loading that results in an SWR of 1.5:1 or more. In the circuit, the components on the 2 dB resistor pad preceding the diode/load compensate for this, as they are tailored to reduce the SWR to less than 1.1:1. Using the simple directional coupler described in my article "Non-Etched SWR Bridge" in the September 1987 issue of *73*, I confirmed the SWR.

Although the power capability of this assembly is 5 watts, forced-air cooling is required at the higher power levels, depending on the measurement period.

The 10 dB Attenuator

See Fig. 2. Inserting the 10 dB attenuator increases power measurement capability to 50 watts. Although it has an attenuation of 10 dB at lower frequencies, at 2 meters and 70 cm, circuit losses increase to 10.8 dB and 12.0 dB, including interconnecting RG-58/U cable losses of 0.4 dB and 0.6 dB, respectively.

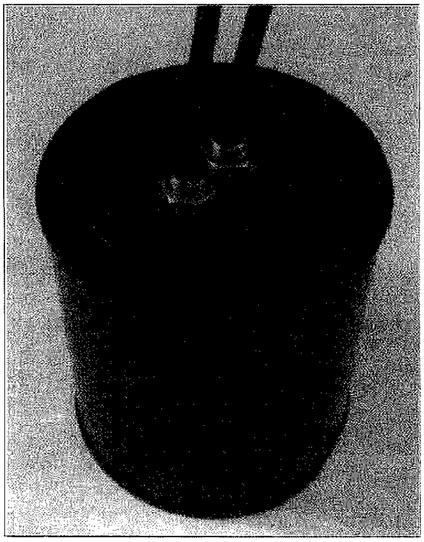

***Photo B.** The 10 dB attenuator.*

Establishing an SWR of less than 1.1:1 at 70 cm was the most critical design consideration. Changes occur with different coolants. If the assembly is tailored for minimum SWR in air, its SWR increases to about 1.3:1 when you put it in vegetable oil. The SWR changes are caused by increased circuit capacitance due to the dielectric. This condition was improved by using household wax, paraffin, instead of oil. *Caution: Paraffin has a relatively low flash temperature; it can be used to make candles.*

Next, to decrease the circuit distributed capacitance, I increased the distance of the components from the circuit board by stacking two layers of PCB at the tie-down pads. This raised the parts connecting positions to about 0.120". The completed assembly has an SWR of less than 1.1:1 at both 70 cm and 2 meters.

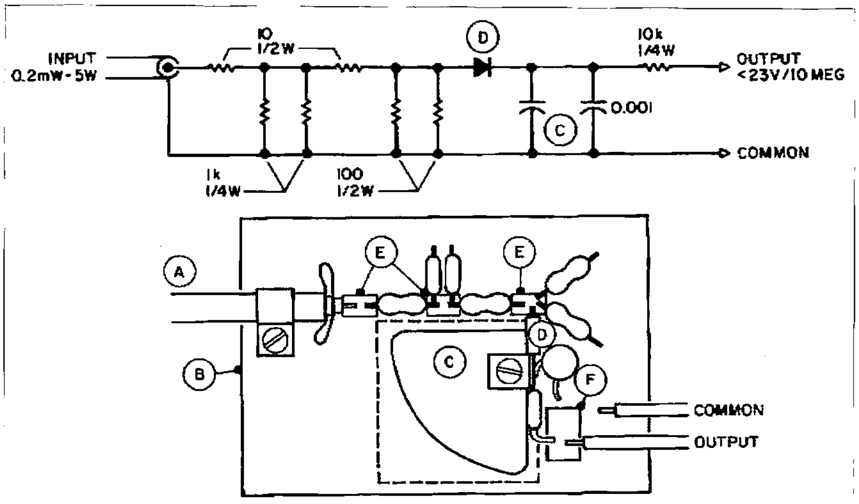

Fig. 1. Schematic and layout of the dummy-load/detector assembly. A. Input, 1' RG-58/U. Fan out braid on connecting end, twist in two segments: solder to PCB with minimum lead lengths. B. Base, 3" x 2" x 1/16" PCB. C. Capacitor. 90 degree circular sector, 1" radius, 0.21"-thick Reynolds sheet aluminum. Surface polish with 220-grit sandpaper to remove burrs. Dielectric, 2.7 mil polyethylene (Ziploc® heavy duty freezer bag). Feed through 2-56 screw with a plastic insulator on the back side. Hole is reamed on both sides with a large drill to prevent shorting to the foil. D. Peak readout diode, 1N34A selected to have a reverse resistance of less than 5 megohms (RS 276-1123). E. Component tie-down pads, 1/4" x 1/8" x 1/16" glass-epoxy PCB. Cemented to base with clear household cement (Elmer's®). F. Output tie-down pad, 3/8" x 1/4" x 1/16" PCB.

Paraffin starts to melt at about 150° F and expands as it melts. You may have a lighted candle on your bench if the components are not immersed in the wax during power dissipation. The container must breathe, and be in an upright position when there is moderate to high power inputs.

The wax may develop voids near the surface when cooling down. Note from the layout that the circuit board is longer than the circuit, forcing the circuit towards the container bottom, away from the wax surface voids. With a 50-watt input, it takes approximately half an hour to liquefy all the wax in a one-pound container.

You can easily calibrate the linearity of the dummy-load/detector assembly with a low-frequency RMS voltage. I use the 60-cycle line with an old step-down transformer and a variac so that I can vary the voltage from about 0 to 50 volts RMS. You can make a 50-ohm source by placing a 50-ohm resistor between the actual output and the transformer AC source (a source impedance of about 5 ohms is considered negligible).

Making Measurements

First, insert the 10 dB attenuator between the 60-cycle line source and the dummy-load/detector assembly. The source is adjusted to a specific diode output value—3 volts, for example. Next, remove the attenuator and note the increased diode output with the dummy-load/detector assembly connected directly to the source. In this case, the value was 9.48 volts. The ratio of the two voltages will be the result of the loss through the attenuator and any change in diode characteristics due to the two different RMS input voltages.

In this example, the 3 volts is about the lower limit before the diode starts a nonlinear rolloff. Therefore, the 3.16 ratio simply indicates the 10 dB attenuator characteristic. As the output voltage is decreased, the ratio will increase: the difference indicates the diode nonlinearity.

Fig. 3 shows a plot of a number of these measurements, with some similar 70-cm measurements for confirming that there are no discrepancies between the low frequency and the 70-cm data. The 5% differences are within measurement error. The easy-to-use table contains the same data. Other 1N34As show reasonable consistency of data. I selected five other diodes measuring 5 megohms or more back resistance and compared them in the dummy-load/detector circuit. All six were compared with the reference diode output adjusted to 0.1 volts. There was only a 10% difference between the low and high values. With 0.5 volt output, the difference was 4%, and with 3 volts, it was less than 1%.

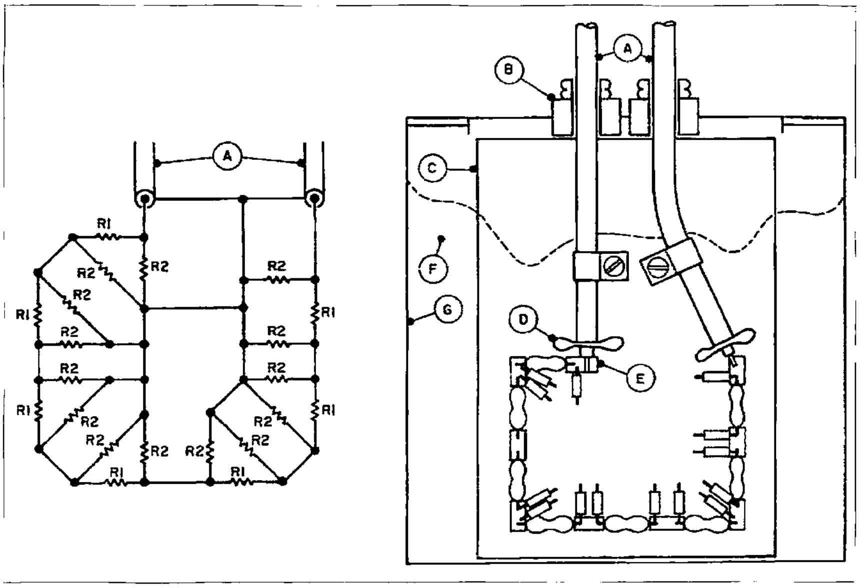

Fig. 2. Schematic and layout of the 10 dB attenuator. R1. 10 ohm 1/2W (7); R2. 1k 1/4W (14). A. Input/Output, 3' RG-58/U. B. Cable bushing, 1/4" clearance hole (I use shaft bushings from old potentiometers). C. Component mounting board, 3-1/2" x 2-3/8" x 1/16" PCB. D. Fan out end cable braid, twist in two segments, solder to PCB with minimum lead lengths. E. Component tie-down pads (9), double thickness glass-epoxy PCB, 1/4" x 1/8" x 1/8. S Pieces cemented together and into position with clear household cement (Elmer's®). F. Coolant, household wax (paraffin). Fill container with melted wax to a quarter-inch from the top. To melt wax, insert the container in hot water (about 200° F). G. Container, one-pint paint can.

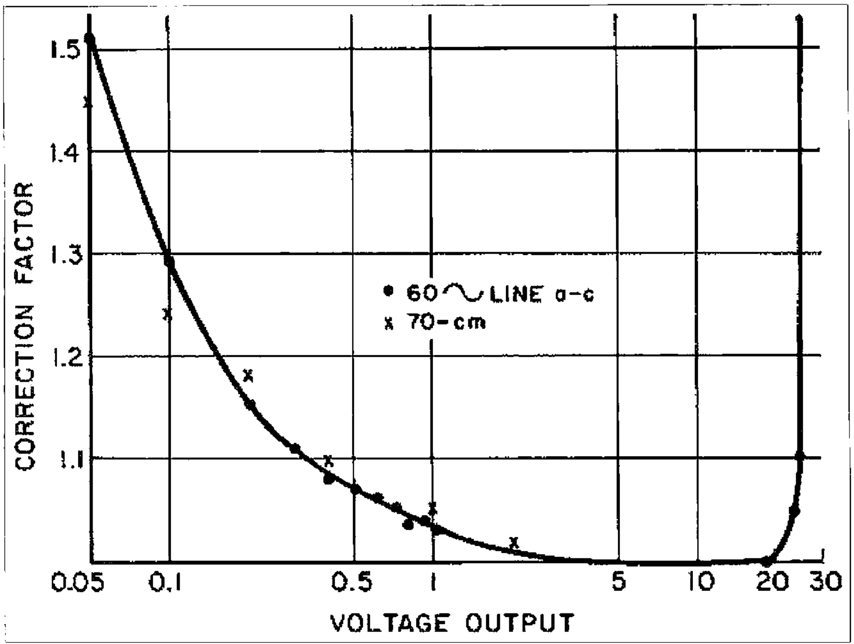

Fig. 3. Diode linearity characteristics (also see Table 1).

The remaining task is to calibrate the dummy-load/detector output as a function of input power. I used a thermal calibration device that's calibrated at a particular power level, then replaced with the dummy-load/detector for a one-point calibration using the identical input power level. The thermal assembly (see Fig. 4) is simply two parallel 100-ohm, 1/4-watt resistors with a thermistor in thermal conduct with the resistors. The layout minimizes thermal mass so that the resistor thermal power results in a relatively rapid temperature gradient.

Testing the device with the SWR directional coupler confirms an SWR of less than 1.1:1. It's first calibrated with DC power input. First, a foam cup is placed over the assembly to prevent effects from possible variable air disturbances. Then power is applied and the thermistor resistance is noted at one-, two-, and three-minute intervals. The resulting thermistor temperature gradient is unique for a particular power input. The assembly can be cooled off to a predetermined reference temperature (near room temperature) in about the same time required for the power-on calibration run by using a forced-air blower. The assembly is calibrated with DC power in increments of 0.25 watts up to 2 watts. See the plot in Fig. 5. Repeated measurements indicate excellent data consistency.

The dummy-load/readout was calibrated using three levels of power: 0.5, 1.0, and 2.0 watts at both 70 cm and 2 meters. From this data, a k value was established for

$$P = \frac{(kE)^2}{50}$$

The k value turned out to be 1.0 at 70 cm and 0.94 at 2 meters, indicating the blackbody/readout assembly has an attenuation at 70 cm. That's 0.5 dB greater than at 2 meters.

To confirm reasonable thermal calibrator performance, I calculated the 2-watt power level with the peak reading from the dummy-load/detector, a 0.707 RMS conversion, and the calculated attenuation of the blackbody circuit (2.1 dB). This calculated power level was 1.0 dB higher at 70 cm and 0.4 dB higher at 2 meters, compared to the thermal calibration method. Such loss factors in with the dummy-load circuit are considered reasonable. As an example, 0.3 dB of this loss at 70 cm can be attributed to the RG-58/U interconnecting cables. Much larger losses would have indicated an input having spurious responses.

You may be thinking: Is this exercise really worthwhile? So I have an SWR of 1.5; calculations show that this will only cause a measurement error of 4%. However, the calculation assumes the effective load, which in this case is 33 ohms (capacitive loading from the diode). It's a common error to assume that the loading stays at 50 ohms. The indicated power level will be 0.64 of the actual power instead of the 0.96 when using the proper load.

Once having the dummy-load/detector assembly calibrated versus a sine wave RMS input, purity of an unknown input can be roughly determined. For example, an input having spurs will indicate an abnormally greater output on the dummy-load/detector compared to the same input calibrated with the thermal

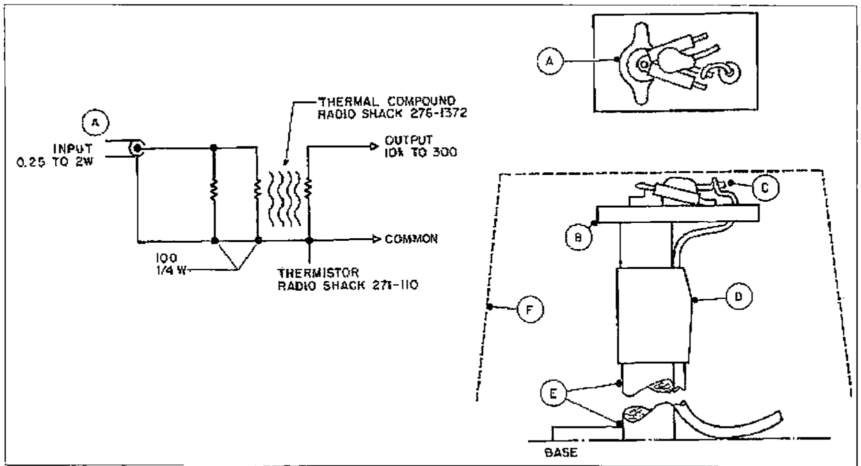

Fig. 4. Schematic and layout of the thermal calibrator. A. Input. 2' RG-58/U. Fan out braid on connecting end, solder to PCB with zero lead length. B. Base, 5/8" x 3/8" x 1/16" PCB. C. Thermistor lead cut short and soldered to a #30 enamel wire. PCB feedthrough hole reamed out with a large drill to avoid shorting to the foil. D. #30 wire connected to a larger size hook-up wire. Fastened to the RG-58/U with tape. E. RG-58/U is fastened to a 6" x 1/4" wooden dowel with tape (maintains the assembly in a vertical position). F. Foam cup is placed over the assembly during the calibration run (avoids air disturbances).

device. The spurs are a good example because they often greatly increase the diode output reading while the thermal power contribution is insignificant.

I'll admit it's hard to get excited about do-it-yourself hardware these days. It's difficult to compete with compact store-bought equipment having all those attractive knobs and buttons. However, I place measurement in a separate category. First, the hardware can be simple. Second, making it yourself forces you to get into the basic engineering underlying the measurement. Taking a measurement using the fundamentals is satisfying, since you end up understanding what is really going on. 73

John Thompson N3KBS. In hopes that you will personally read this letter I want you to know that your October editorial slapped me in the face and said, "Wake up, stupid!" You couldn't have written to me any better if you had mailed a letter to my house. I've ended selling TVs, stereos, and computers at Montgomery Ward and have stopped crying about the lack of opportunity and have decided to make something happen. I've started fixing computers and gadgets and have been successful enough to finance a vacation to Arizona. I've enjoyed several of the books you've recommended. I'm wondering why there hasn't been more use of 900 MHz, which has a lot of room and potential. Thanks for *73*, it's the only ham magazine I've found worth reading. Oh yes, I'm working on losing that extra weight.

Yes, I read my mail. And answer most of it. John, you're right about 900 MHz. I'd love to see a bunch of articles on stuff for that band. . . Wayne.)

Ken Payton KB5ROV. In your editorials you often request letters from your readers letting you know what we have been doing with our time. I find your editorials very interesting and enjoyable because you share your research with your readers and invite us all to join you in reading the same books to gain insight into some subject. I have taken you up on your challenge a few times and am happy to say that I have learned a lot and have had a lot of fun that otherwise I would have missed. For instance: From *Cross Currents*, my wife and I no longer sleep with the electric blanket plugged in. We now use it to warm the bed then unplug it for sleeping. We both feel better for doing this than we thought possible. We have become interested in using magnets for health improvement offered by a company in California. We use some of the magnetic products with positive results. From your *Aids Info* booklet I have built the circuit and we both use it on a regular basis. We use it before going to sleep and find that we rest better. My wife suffers from rather severe cramps at times and has learned that by using this device they are greatly reduced. I have shared your booklet with other people, but have not received any feedback as to whether they use the device. From *Hydrogen Peroxide, Medical Miracle*, I have learned how to cure the common cold. This

Every Ham's Average/Peak Reading RF Wattmeter

The only one you'll ever need.

J. Frank Brumbaugh KB4ZGC
P.O. Box 30
Salinas PR 00751-0030

Ham stations come in all sizes from QRPp to QRO, and most hams like to know just how many milliwatts or hundreds of watts are coming out of their rigs. Until now there has never been a simple, accurate RF wattmeter that is perfect for all legal power levels. The instrument described here will solve all your RF power output requirements, regardless of your power level. Even if you change rigs, going from QRP to QRO or vice versa, you will never need another RF wattmeter.

This wattmeter measures RF power into a 50-ohm resistive load from 100 milliwatts to 1,500 watts in four decade ranges which overlap over 33%, so you'll always know the best range to choose.It can be left in the coax line from your transmitter at all times. It will not affect the impedance of either your receiver or your transmitter. It requires only a small fraction of one percent of your RF output power for operation at any legal power level.

It was designed to use only standard, common components, and can probably be constructed entirely from the contents of most junk boxes and the normal resistors and capacitors most hams keep on hand (or which can be purchased inexpensively from many mail order parts dealers or, for even less, from local hams or at hamfest flea markets).

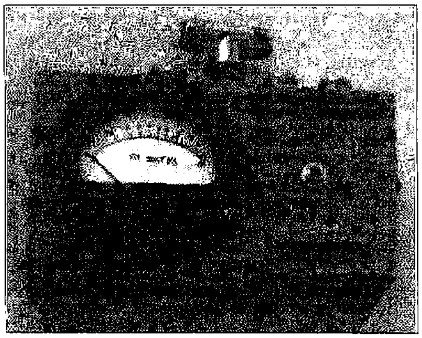

***Photo A.** KB4ZGC's average/peak reading RF wattmeter.*

This instrument is very simple. It's easy to construct in a few hours, very easy to calibrate with a 9-volt battery, potentiometer and DMM, and using it is as simple as glancing at the indication on its meter.

The four power measurement ranges are: 100 mW to 1.5 W; 1 W to 15 W; 10 W to 150 W; and 100 W to 1,500 W. A toggle switch, the only control, allows a choice of average or peak power indication. (Average—actually RMS—power is key-down constant carrier, the actual amount of RF your rig produces. Peak power is that caused by voice peaks on AM or SSB.)

As designed, accuracy is ± 1%, ± the accuracy with which you calibrate the new scale on the meter used. Because the scale is hand calibrated, the normal ± 2% error of normal meter movements is eliminated. Operation is accurate from 1.8 to 30 MHz. It may also be useful through 6 and 2 meters, but I was unable to test on these frequencies.

Circuit Description

Each RF power range has its own coaxial connector: J1-1.5 W; J2-15 W; J3-150 W; J4-1,500 W. A coaxial tee connects the wattmeter in shunt with the coaxial line between the transmitter and the load, which must be 50 ohms resistive if accuracy is to be maintained. One arm of the tee connects to the transmitter, and the other connects to the load.

With switch S1 at AV (average) and the transmitter producing an A1 carrier, the power output delivered to the 50-ohm load is displayed on the meter. The AV position of S1 can be used on all modes.

With switch S1 at PK (peak) while speaking into the microphone of an AM or SSB transmitter, the needle of meter M1 will follow voice power and indicate peak power on voice peaks. The time constant for the peak power mode is approximately 1.9 seconds. Increasing or decreasing the value of capacitor C1 will increase or decrease the time constant, respectively. The resistance of meter M1, plus meter multiplier resistors R1 and R2, in conjunction with the capacitance of C1, establish the time constant.

With an RF input to J1 between 100 milliwatts and 1.5 watts, the RF is rectified by germanium diode D1, filtered by C2, and the resulting DC voltage is applied through R1 and R2 in series to meter M1, which indicates the level of RF power applied to the load.

With greater RF power applied to the load, using any of the remaining coax input connectors (J2, J3, J4 as appropriate), the RF is divided by a ± 1% resistive divider, sampled and rectified at the tap on the divider, filtered by C2/C3, and applied through R1 and R2 to meter M1, as described in the preceding paragraph.

Construction

This instrument was carefully designed to use all standard parts values, which saves cost, time and one's temper. Using a digital ohmmeter for greatest accuracy, begin measuring your stock of 1/4 W 5% resistors and select those which measure to within ± 1% of the marked value. All resistors except R7 are 1/4 W.

R7 is specified in the Parts List as 1/2 or 1 watt, ± 1%. This resistor will be called upon to dissipate approximately

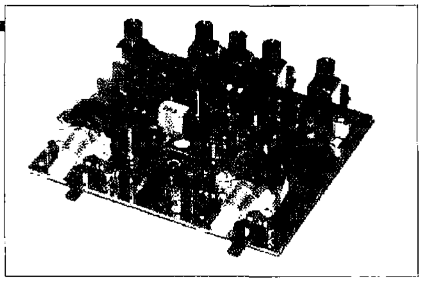
A Hot, Selective 2m Receiver You Can Have Fun Building

Take a look at the Hamtronics R-100, a great little receiver kit.



Larry Antonuk WB9RRT
Box 452
Marlborough NH 03455

Practically everyone has heard some version of the story. Two hams have hiked up to the top of Mount Something-or-Other, and are viewing all of the impressive towers and antennas at the commercial radio site. The first ham whips out his new Whiz-Bang 2000, a fully synthesized, multiband wonder the size of a cigarette pack. He brings up the 2m repeater back home, and calls his wife on the autopatch to let her know they made the trip OK.

As he begins the conversation, he finds that his wife's audio is choppy, and whole chunks are being lost out of her side of the QSO. Thinking that something must be wrong with the home repeater, the second ham pulls his handheld out of the pack—a 15-year-old, single-channel, crystal rig. To the surprise of both the hams, the older handheld hears the repeater audio loud and clear. It now looks like the Whiz-Bang 2000 must have a problem!

Totally dismayed, the first ham continues to listen to the traffic on the home repeater. It continues to be choppy, erratic, and overall lousy—but the old handheld is doing just fine. Later that night the first ham puts both radios on his test bench, and tests their sensitivity with a signal generator. He finds that they both measure exactly the same; if anything, the Whiz-Bang is just a tad "hotter." What gives?

What gives is that it takes more to pull in a signal than just being able to hear the weak one you want to hear; you also need to be able to *not* hear the ones you *don't* want to hear. In the case of our friends on the mountain, the strong signals from the nearby commercial transmitters were *desensitizing* the first ham's receiver. The signals were strong enough to pass right into the mixer circuits of the receiver and simply overwhelm it, making it impossible for the receiver to hear the weaker distant repeater signal. But how come the old "brick" worked when the Whiz-Bang didn't? It worked simply because the older radio had better selectivity than the newer one, which is often the case these days.

Selectivity

Selectivity is just the radio's ability to reject unwanted signals. These interfering signals can cause problems that you hear in the speaker, or they may remain silent, but prevent you from hearing something you do want to hear. The older radio was designed to work on a fixed channel, and had dozens of coils and caps tuned to just that frequency. All of this hardware made up a set of tuned circuits whose sole purpose in life was to keep out unwanted carriers, harmonics, and spurs—both from outside the radio, and from circuits inside the radio itself. Of course, all of the hardware added to the size and weight of the radio, resulting in the nickname of "brick."

These days, if you want to build a radio the size of a cigarette pack, some compromises have to be made. First, if you expect it to tune from one end of the band to the other without retuning the front end, some of those coils and caps will have to be eliminated. There are some tricks that allow the radio to electronically tune itself, but in general, the front ends of most synthesized rigs are "broad as a barn." In addition, if you want the radio to be tiny, don't expect to put any of those big helical filters and triple-tuned RF stages in the thing—they take up too much space. Generally speaking, this describes most synthesized radios today. They have loads of cool features, but often can't stack up in terms of selectivity.

So what do you do if you really must have the best selectivity? For instance, what if our two hams were up on that mountain scouting out a spot for a new repeater. The receiver in the repeater would have to stand up to the same RF beating that caused the Whiz-Bang 2000 to tuck its tail between its legs. One thing that can be done is to convert a commercial rig to the ham bands, if you have the money. A better option might be to check out the new R-100 VHF FM receiver from Hamtronics.

A Solution: The R-100

The R-100 is the latest product in a long line of high quality receivers built by Hamtronics. Boasting a selectivity specification that exceeds that of most ham and commercial receivers on the market, the R-100 is available in the 50, 72, 144, and 220 MHz bands. Designed to replace the R144/R220 and R76 series of receivers, the R-100 utilizes all of the features that have made the previous units such winners—triple-tuned front end filters, crystal and ceramic IF filters, low noise FETs for the RF amp and mixer. In addition, the R-100 features an improved, snappier squelch circuit, as well as new output signals that will allow easier interfacing to various repeater or control applications—low-level squelched audio, discriminator audio, and a COS point.

73 Review

The Icom 706
All-Band Transceiver

Reviewed by a very happy user.

Phil Salas AD5X
1517 Creekside Drive
Richardson TX 75081

I recently purchased an Icom IC-706 transceiver to replace my TS-50S for mobile and portable operation. What was wrong with the TS-50S? Absolutely nothing. The TS-50S is a great radio and has provided me many hours of enjoyable "hamming." However, with the sunspots beginning to perk up, I have been seriously considering getting back on 6 meters. I found that a good used 6 meter solid-state all-mode rig would cost me around $500. Therefore, I figured that if I sold my TS-50S and added the $500 the 6 meter rig would cost, I'd have the money for a new IC-706.

The Radio

OK - what is the IC-706? Well, basically it is an all-mode 160-through-2 meter transceiver that is no bigger than most 2 meter FM rigs (dimensions are 6-9/16"W x 2-9/32"H x 9"D, including all projections)! And when I say all-mode, I mean CW, SSB, AM, FM, RTTY. In addition, it will receive wideband FM.

This is pretty neat—you can put it in your car and receive AM and FM broadcast stations, operate 2 meter mobile FM, and operate HF mobile all with the same rig! And, to make it easy to find a place for the IC-706, the front panel detaches from the rest of the radio and can be easily mounted anywhere you've got room. The rest of the radio can be up to 23 feet away (3 meter and 7 meter remote cables are available)!

The IC-706 puts out a full 100 watts from 160 through 6 meters, and 10 watts on 2 meters. The receiver tunes continuously from 300 kHz to 200 MHz. It is also loaded with most of the same features that you normally see in a full-size base HF rig. It includes 101 memories (which is a lot more than my brain has), band and memory scanning, IF shift, RIT, noise blanker, audio speech processor, and an internal keyer.

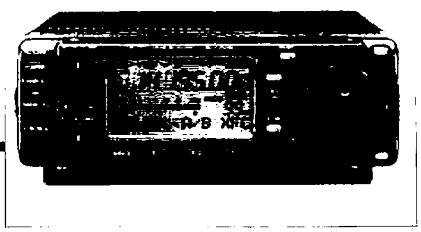
The keyer can be programmed for left- or right-handed paddle users, a straight key, or you can use the UP/DOWN microphone buttons! I found that I could operate the keyer quite well, with a little practice, using the microphone buttons up to about 20 wpm. You can add one optional narrow filter, so you need to choose between a narrow SSB filter (1.8 kHz), a 500 Hz CW filter, or a 250 Hz CW filter. You can vary the CW offset from 300-900 Hz, select a CW reverse mode, vary keyer speed and weight, and offset the SSB carrier plus or minus 200 Hz to tailor the audio response of the transmitter.

Operating

Operating the IC-706 is not all that difficult, considering the huge number of features and the few controls. Icom did an excellent job of building user-friendly menus and displays for accessing these features. Pressing the DISPLAY button brings up major features, and then the MENU button scrolls through subfeatures of the displays. Once you've been through the instruction book once, you should be able to fully operate

P-Out	Setting	Current (160m)	Current (6m)
3.5W	L	5.7A	6.0A
5W	1	6.5A	6.7A
10W	2	7.7A	8.0A
20W	3	9A	10A
30W	5	11A	12A
50W	6	12.7A	5A
100W	H	18A	20A

Table 1.



the radio, only having to go back to the book infrequently. Basic operation of the radio is very easy. About the only thing you need to know is how to change bands, because the default settings pretty much provide you with what is necessary. Just plug in the microphone or key and go! Now, let's get into a little more detail.

Band changing is done with the TS (Tuning Step) button. The first press of this button illuminates two arrows over the 10 MHz/1 MHz portion of the display. When you turn the tuning knob, the bands will change sequentially up or down (includes 15 MHz for WWV). A second push of the TS button puts a single arrow over the 1 MHz portion of the display and permits you to tune 1 MHz at a time. The next button press lets you tune in 1 kHz increments for rapid movement around a band, and the last press tunes in 10 Hz increments for normal tuning. Normally, you punch TS once, change bands, and then punch it three more times to get you back to normal tuning. The radio beeps every time you push a button, so this is a pretty straight forward operation and quickly becomes automatic.

On transmit, you can meter output power, ALC or SWR, based on a simple menu selection. You use the ALC reading to digitally set the microphone gain from one of the menus. The audio speech processor is easily turned on and off and works very well. The output power is continuously variable from another menu from less than 5 watts to 100 watts. My IC-706 turns down to 3.5 watts. This is great for the QRP enthusiast, though the current consumption of this radio is not what QRP-types are used to. Lots of features mean lots of

Continued on page 60

Every Ham's Average/Peak

Continued from page 36

one-half watt during 1,500-watt peaks only, so for all practical purposes a half-watt resistor will suffice. Using a 1-watt ± 1% resistor will remove all doubt for QRO operators.

The size and shape of the enclosure you use, either a commercial or home-brew aluminum box, or one made of printed circuit board stock, will depend on the physical size of the 100 μA meter you use and the space required by the four SO-239 or other RF connectors. I used an LMB-138 aluminum box 6-1/2" wide by 3-1/2" high by 2-1/8" deep because my surplus meter was round, with a diameter of 3-1/2-inches. I had to saw about 3/8" off both meter studs so it would fit within the shallow depth of my enclosure.

The four germanium diodes required (D1, D2, D3, D4) must all have the same type number, but it is not necessary to match them for forward resistance.

New 100 μA meters are far too expensive for most of us to even consider. If you don't own one or can't get one from a local ham or a flea market, you can do as I did. The meter I used is 3-1/2" diameter, round, and came in a "grab bag" of five used meters (no choice) purchased from Fair Radio Sales Co., P.O. Box 1105, Lima, OH 45802-1105, Catalog No. 47-84, $10 plus shipping. Over the past 10 years I have purchased seven of these "grab bag" assortments, and all meters have been high quality, with d'Arsonval movements, some with jeweled bearings, made by Marion, Westinghouse, Simpson, etc. Size varied from 2-1/2" to 6"; round, square and rectangular. All have been removed from equipment and tested before resale. While meter scales are sometimes non-standard, there have always been at least one, and often two, meters with 50 or 100 μA movements. The remaining meters have always had 0-1 mA movements.

Some meters may contain internal multipliers or shunts and sometimes rectifiers, but these are easy to locate and remove. If you have such a meter and are unfamiliar with modifying meters, please refer to my article, "Use Those Surplus Meters," *73 Amateur Radio Today*, January 1992, page 42. You can order photocopies from the publisher if you don't have a set of back issues on the shelf (tsk!). All in all, for $2 you'll have a fine 100 μA meter for your RF wattmeter, and have four more useful meters for future projects.

It will be preferable if all four coaxial connectors are mounted touching each other, either in a line or square. This allows for very short leads for all components carrying RF, extremely important to achieve the design accuracy. There is always some unavoidable RF leakage which will be contained by the enclosure, but which forces a deviation from the calculated resistance values to maintain the accuracy of this instrument.

The four coaxial connectors should be mounted using four sets of 4-40 screws, lock washers and nuts. Be sure to scrape any paint from areas where these connectors are mounted, to assure excellent grounding to the enclosure. Two terminal strips with one ground and one insulated terminal will later be mounted using two of the connector mounting screws, depending upon the arrangement of the connectors.

Wrap a fine wire around both terminals of the meter M1, shorting them together to protect the sensitive movement. Then mount the meter on the panel temporarily. It will be removed for calibration, then replaced and connected into the circuit permanently. Temporarily mounting the meter now ensures there will be no components or wiring which would interfere with the meter case or terminals.

Cut one lead of R3, R5 and R7 to 3/16". Hold the short lead of R3 close to the resistor body with the tip of needle-nose pliers. Melt solder into the center pin of J2. When the solder is molten, insert the short lead of R3 into the molten solder, making certain not to move it while the solder solidifies. This is no place for a cold solder joint!

Repeat this procedure, soldering the short lead of R5 to the center pin of J3, and the short lead of R7 to the center pin of J4.

Now mount the two terminal strips on connector mounting screws, positioning the terminal strips so their terminals are approximately centered below and between J1 and J2, and between J3 and J4. Tighten the mounting hardware, using additional lock washers if required.

Because of the necessity to reduce to the greatest extent possible the chance that any RF can leak off where it isn't

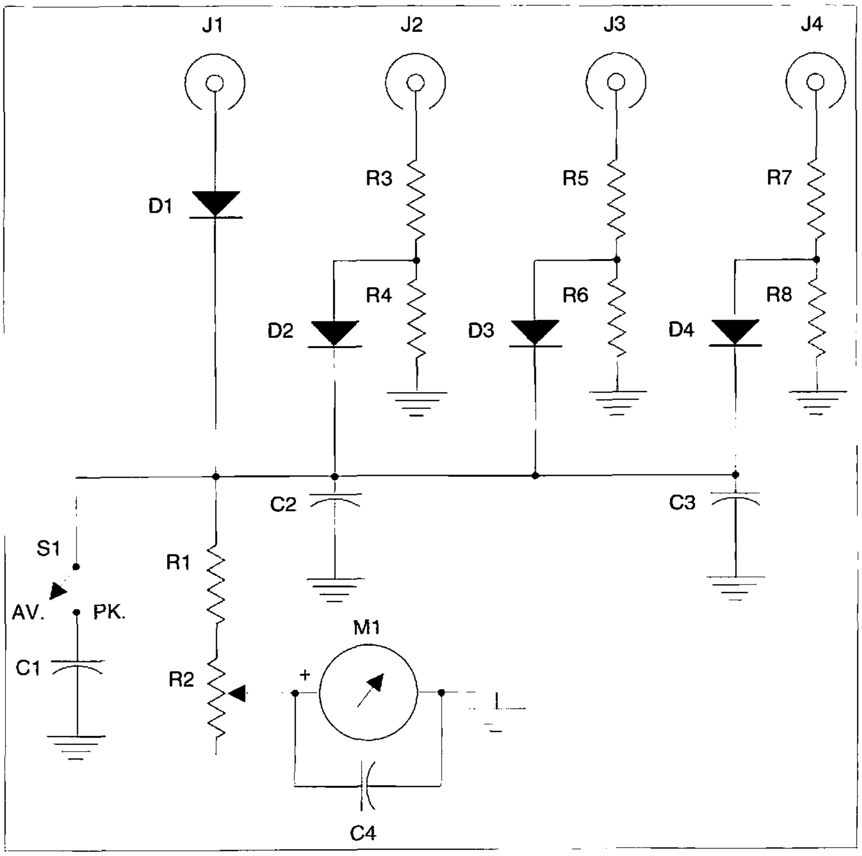


Fig. 1. Schematic for the RF wattmeter.

wanted, thus destroying the accuracy of this instrument, connections to the free ends of R3, R5 and R7 must be made "up in the air," spaced away from the enclosure walls and the meter movement. If space requires, J1 can be safely mounted near the meter, but the others should be some distance from the meter.

Now solder one end of R4 to the free end of R3, against the body of both resistors. Clip the end of R4 at this junction but leave the free end of R3 attached. Route the remaining lead of R4 to the ground terminal on the appropriate terminal strip, but do not solder it at this time. Make sure the soldered junction of R3 and R4 is "up in the air" and in the clear. Now, using needlenose pliers to hold the anode of diode D2 close to its body, connect the anode lead to the junction of R3 and R4, and solder. Clip the extending leads of R3 and D2. Route the cathode lead of D2 to the insulated terminal of the strip to which R4 has been connected, but do not solder yet.

Cut the anode lead of D1 to 3/16". Hold this end of the lead in the tip of needlenose pliers. Melt solder in the center pin of J1. When the solder is melted, insert the short anode lead of D1 into the center pin of J1 and hold it steady until the solder has solidified. Continue holding the diode anode lead with the needlenose pliers until the solder joint is cool, to protect the diode from excessive heat.

Route the cathode lead of D1 to the insulated terminal to which the cathode

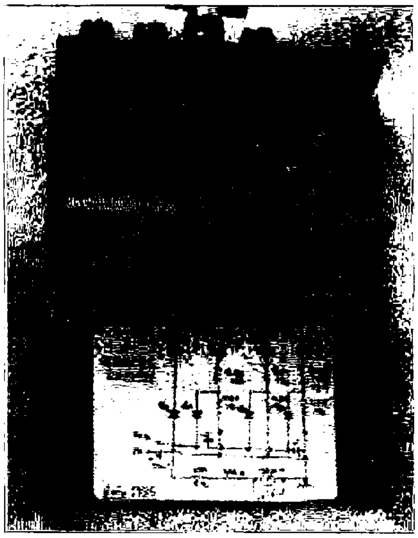

Photo B. Inside the RF wattmeter.

lead of D2 has been connected, but do not solder it yet. Connect a short length of insulated hookup wire to this insulated terminal. Solder this wire and the two diode cathode leads on the insulated terminal using an alligator clip or needlenose pliers on both diode leads to protect them from excessive heat. Connect the other end of this wire to the insulated terminal on the other terminal strip. Solder the lead from R4 on the grounded terminal strip. Solder C2 between the holes on the insulated and grounded terminals. C3 can likewise be soldered between the holes on the two terminals on the other terminal strip at this time.

Connect and solder one lead of R6 to the free end of R5, routing the free lead of R6 to the grounded terminal of the other strip, as was described for the circuit connected to J2. Connect the anode lead of D3, holding it with needlenose pliers, to the junction of R5 and R6 as described for D2, and solder. Clip free resistor and diode leads from the R5-R6 junction. Route the diode cathode lead to the insulated terminal of the remaining terminal strip but do not solder.

Connect and solder one lead of R8 to the free end of R7, routing the free lead of R8 to the grounded terminal of the strip where R6 is connected. Solder this connection. Clip off the free excess lead of R8 at its junction with R7. Holding the anode lead of D4 with needlenose pliers, connect and solder to the junction of R7 and R8. Clip off the excess diode lead. Route the cathode lead of D4 to the insulated terminal where the lead from D3 is connected. Connect a short length of insulated hookup wire to this insulated terminal. Using an alligator clip or needlenose pliers on the diode leads, solder this terminal.

Closely inspect all solder joints just made to ensure they are shiny and all connections are solid. If necessary, gently move the three resistor/diode circuits so their junctions are "up in the air" and away from each other and the walls of the enclosure.

Caution: Before any further construction can be accomplished, meter M1 must be calibrated. Refer now to the calibration section following. When calibration has been finished, return to this section to complete the construction.

With calibration completed and the meter reassembled, mount the meter on the panel. Select a small terminal strip with two insulated terminals. Connect R1 between the terminals but do not solder yet. Mount the terminal strip on one of the meter mounting screws, using additional lock washers if required.

Connect the wire leading from the terminal strip which ties all diode cathodes together to one end of R1 and solder. This wire carries only low voltage DC but should be routed away from the resistors carrying RF. Its length is immaterial.

R2 is a trimpot. Because they are made in various configurations it is up to you to determine how to install the one you use. I used a small, square trimpot, single turn, with a side adjustment. I used Krazy Glue® to attach it to the rear surface of the meter.

Solder a length of insulated hookup wire to the free terminal of R1. Solder the other end of the wire to either of the end terminals of R2. Solder another length of wire between the wiper terminal of R2 and the positive terminal of M1. Solder a wire between the negative terminal of M1, to a ground lug mounted on either a meter mounting screw or one of the screws mounting the nearest coax connector. Connect and solder C4 across the terminals of M1.

If you are including the peak reading capability in this instrument, mount switch S1 and capacitor C1. Be certain of the polarity of C1. Connect a short length of insulated hookup wire from the free terminal of S1 to the terminal where R1 and the wire from the diode junctions are connected, and solder.

There are three short tests which should be made before closing the case. Place S1 in the AV position. Attach the 50-ohm dummy load which you normally use in your station to J2. Using a digital ohmmeter, measure the resistance to ground from the junction of R3/D2/R4. Be certain the red (positive) lead goes to this junction. The resistance should be in the vicinity of 2,385 ohms.

Connect the 50-ohm dummy load to J3 and measure from the junction of R5/D3/R6 to ground as described above. The resistance should be in the vicinity of 3,140 ohms.

Connect the 50-ohm dummy load to J4 and measure the resistance from the junction of R7/D4/R8 to ground as described above. The resistance should be in the vicinity of 1,111 ohms.

The resistances just measured bear little relationship to the values of R4, R6 and R8. This is because of the several parallel resistance paths inherent in the design of this instrument. These values are for guidance and are not intended to be exact; merely close. The tolerances of the ± 1% resistors, the forward resistance of diodes, and the exact resistance of the 50-ohm dummy load all affect the resistances just measured.

Calibration

Because the root-mean-square value of an AC voltage (RF) waveform represents the effective voltage across a resistance, this instrument can be easily calibrated with a variable DC voltage. Less than 9 volts is required, so a 9-volt battery and a potentiometer is the simplest calibration source, along with a DMM for accurate voltage measurements. The overall measurement accuracy is greatly affected by the care with which the meter is calibrated by hand.

Remove the meter from its case so you have access to the face. If there is a scale, the numbers and calibration lines can be carefully covered with a product such as Liquid Paper® (used for making corrections in typed material). Use it sparingly, and be careful not to obliterate the arc. Use care not to bend the needle! You may wish to remove the meter face to make this work easier. The face will have to be replaced on the meter before calibration can proceed.

Refer to Figure 2, the calibration setup, and make the connections between a germanium diode, R1, R2, M1, the calibration potentiometer, DMM and a 9-volt battery.

Set R2 to its maximum resistance, and also set the calibration pot to its minimum resistance with its wiper at the negative end before connecting the battery. You may also use any other DC voltage source handy, including the station power supply, of course.

Table 1 lists the 15 voltages required to calibrate the meter scale between 1 and 15. The more accurately you establish these voltages and the care with which you mark each point on the new meter scale, the greater will be the overall accuracy of this instrument. Although this is of major importance only to QRP and QRPp operation, it will still be nice to know that "What you see is what you get" when you glance at the meter later.

Adjust the calibration pot so the DMM indicates 8.66 volts. Then adjust R2 for a full-scale indication on M1. Mark this "15."

Caution: Do not touch the setting of R2 after this initial calibration is made. Adjust the calibration pot so the DMM indicates 8.37 volts. Mark the meter needle location on the scale "14."

Referring to Table 1, continue marking calibration points on the meter scale with the numbers equivalent to the calibration voltages listed.

It will be preferable if you merely make tick marks on the meter scale during calibration. You can extend them into short lines and add the numbers when calibration is complete. The larger the physical size of your meter, the easier and more accurate will be the calibrations. Because the scale is nonlinear, the higher power calibrations will be more crowded than those at the lower end. Also, only about 2/3 of the available scale is calibrated so that 1-1/2 decades can be covered on each range, providing the desirable overlap between ranges.

Because "1" on the 1.5-watt scale represents 100 mW, QRPp operators may be tempted to calibrate their scale below this point. However, this is not recommended because of the approach of the low RF voltage level to that of the germanium diode conduction knee. Serious inaccuracies could result.

Operation

The operation of this RF wattmeter is simple. Connect a coaxial tee adapter to the appropriate connector on the wattmeter. Connect the transmitter output to one leg of the tee, and a 50-ohm dummy load sufficiently robust to dissipate suspected transmitter power output to the other leg safely.

Key the transmitter and the power output will be indicated by the wattmeter. With an antenna or an antenna tuner and antenna presenting an SWR of 1:1 connected replacing the dummy load, the wattmeter will accurately indicate the output from your transmitter.

For modes other than AM or SSB, S1 will normally be set at AV. The PK position is included to monitor peak power on AM and SSB. With S1 at AV and operating AM or SSB, the wattmeter needle will swing wildly but the peaks indicated are the result of inertia and do not accurately display actual peak power.

Should you inadvertently apply power to this instrument without a 50-ohm resistive load connected, you might blow a diode, and you might bend the needle in a worst case, but no other damage should result. So, make certain you connect to the proper connector on the wattmeter. If you are unsure of the power output from a particular transmitter, start at J4 and work your way down.

Comments

Although the resistance tolerances of ± 1% are specified for resistors in the RF portions of the circuit for greatest accuracy, especially at the QRP range of 1-15 watts, the QRPp accuracy is totally a function of the accuracy of the calibration voltages and the care with which the meter scale was marked. The inaccuracies resulting from the use of 2% or even 5% resistors on the 150- and 1,500-watt ranges are much less important. A watt or two at these power levels is inconsequential, so you can fudge a little on these two highest ranges without being very concerned.

Peak power indications can be made usefully only on those modes where the output power actually varies. It is of no

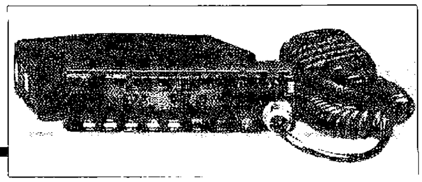
The Alinco DR-610T

A tough new dual-band, remote-head mobile/base transceiver.



Gordon West WB6NOA
2414 College Drive
Costa Mesa CA 92626

What could Alinco Electronics do to top what the rival "big three" have done with a detachable-head, 2 meter/440 MHz, mobile transceiver? It's tough to surpass all of those great features already found in the Kenwood, Yaesu, and Icom versions of this product. The new Alinco DR-610T has these same features, too:

•High power, 40 watts-50 watts on 2 meter VHF
•Moderate power, 35 watts out on UHF
•Full frequency receive coverage VHF, 108 MHz-173 MHz
•Full frequency receive coverage UHF, 420 MHz-470 MHz
•100+ memory channels between both bands
•Multiple scan functions, including priority
•Monoband dual-receive
•CTCSS encode
•Multiple output levels
•Remote detachable head
•Crossband duplex, 9600/1200 bps packet compatible
•Time-out timer
•Phone patch auto dialer

However, the Alinco DR-610T may top the competition when it comes to an extremely important feature for ham operators wanting maximum value at the best price—the DR-610T was seen selling for at least $85 less than comparable Kenwood, Yaesu, Icom, and Standard Radio dual-band transceivers. The DR-610T is also the first dual-band transceiver with built-in LITZ, "long tone zero." This function, described in a *QST* article several months ago, may soon be one of the best ways to signal for help on simplex or repeater duplex frequencies late at night when the control operators may have their equipment in the automatic unmonitored mode. The LITZ signal is accomplished by holding the "zero" DTMF button down on "transmit" for more than three seconds to alert another Alinco DR-610T, or any other system with LITZ capability, that an important message is on frequency. When a DR-610T receives a LITZ signal, it will sound a loud SOS CW alerting tone, regardless of the speaker's volume setting, and flash a "LIT" on the LCD display to alert you that an incoming three-second zero has been detected. This feature allows a control operator and all hams to monitor (silently) a specific frequency at night for an "SOS" LITZ call.

"The built-in LITZ feature allows a control operator and all hams to monitor (silently) a specific frequency at night for an "SOS" LITZ call."

Alinco President Mark Morisato describes the DR-610T as "designed for convenience, with advanced operating circuitry already built in." He is describing the LITZ function, built-in duplexer, digital squelch circuitry, and capabilities for adding an EJ-23U memory chip to program a whopping 240 channels in fail-safe memory. Dave Chernow KE6TFO, sales coordinator for Alinco, adds, "Our DR-610T is an upgraded success based on our DR-600, which continues to be one of the hottest-selling dual-band mobile/base transceivers throughout the country."

The DR-610T is shipped with one of the most complete large-format instruction manuals that I have seen for some time. Read the manual before turning on the equipment—this will save you agonizing minutes when you get into keystrokes that appear to freeze channel-changing capabilities. The set is no more complex to operate than any other brand of transceiver but, as with all new equipment, you *must* read the first couple of pages to get a feel for how you program frequencies and begin to memorize simple and duplex channels.

The Alinco DR-610T wires into 12 volts, and needs 12 amps for full power output. Yes, you could run it straight off a cigarette lighter plug, but we measured a 1-1/2 volt drop, and this decreases VHF/UHF power output by more than 10 watts. If you want to squeeze every last drop out of your new set, wire it directly to the battery, making sure to fuse both the positive and negative leads within an inch of the battery connection. Alinco provides you with the fuses and fuse holders at the ends of the red and black wires.

The DR-610T has a built-in duplexer, and this simplifies the hookup to your dual-band antenna. Whether you are running the equipment mobile or base, a single coax feed makes for quick hookup to the single antenna system. Few of us use separate 2 meter and 440 MHz antennas, so run your coax, hook into the antenna system, and you are all set.

Optional Features

If you're going to remote-mount the head, you will want to buy the EDS-2 front panel remote cable kit, and the EBC-8 front panel bracket. You could

also order the EDS-1 junction box that allows the microphone to hook up to something beneath your seat, rather than off the remote head that you may want to put over the rearview mirror. Many new vehicles come with capabilities for running the remote up high, and the junction box keeps the microphone from dangling in front of you.

I would also encourage you to purchase the optional tone decode squelch unit EG-24U, which would allow you to radio-control the operation of your equipment from another hand-held transceiver. This is a handy feature if you regularly run your mobile unit in the crossband duplex mode and want to radio-control it on or off, or to change frequencies by remote. Whenever running equipment in the dual-band crossband mode, check with local frequency coordinators to ensure that you are using this advanced feature properly, and remember that controlling a "repeater" must be done on frequencies other than its normal input.

And as long as you are inside the set, you might as well purchase and plug in EG-23U, the additional memory unit that expands your 120 channels to 240 channels. Now you can program every living repeater, aeronautical receive channel, public safety channel, weather channel, police and fire channel, and just about anything else you want, into memory so you never need to carry that little black memory book with you again!

The full-featured EMS-12 microphone is shipped with the USA model. No longer must you buy a more elaborate microphone to go along with all of the dual-band capabilities for which you are programming the set. The microphone is relatively lightweight and has its own unique Alinco feel. I have friends who have tried out the equipment and have immediately fallen in love with it.

Operation

When everything is hooked up, turn on the power by depressing the power button located just above the mike jack. Like all dual-band transceivers, it comes up in VFO mode at 145 MHz for 2 meters, and 445 MHz for the 70 cm band. There is nothing loaded into memory. You know, with CPU technology and cloning, I wish that incoming transceivers would have the US repeater band plan stored. Which manufacturer will be first to pre-load common popular repeater pairs so the new operator can go into memory and start receiving radio excitement on 2 meters and 440?

"When it comes to group pager modes, selective calling, all calling, and group calling, Alinco has moved well ahead of other manufacturers in providing documentation and explanation in their user manual."

Unlike the Yaesu FT-8500, the new Alinco has no cloning capabilities nor does it offer alphanumerics user-programmable on the display. But it is not as expensive as the Yaesu set, either!

The LCD display on the Alinco looks very good, and is easily viewed from the top, bottom, and sides. Volume controls for both VHF and UHF are side-by-side, and you have plenty of volume output for use in noisy vehicles. The squelch control is logically concentric to the volume controls, and squelch action is normal for this type of transceiver. Signals just in and out of squelch will chatter, and this is typical of "hard squelch" found in almost all equipment except for some Icom transceivers that use a new soft squelch feature.

You select VHF or UHF by pushing the volume control in for that particular band. You can dial the frequency from the front panel knob, or push the microphone up/down keys, or program the frequency from the microphone. The big channel-changing knob on the front has a logical push capability to enable 1 MHz quick-steps. This allows you to rapidly go from ham to public service without having to fish around to find the 1 MHz button—a good feature.

The transmit power was 52 watts on VHF into a perfect match, and 37 watts on UHF. A small fan comes on immediately to keep things cool. An LCD bar graph illustrates high power, medium power, and low power. However, the LCD graphs don't change much with a major antenna mismatch. On older single-band and dual-band transceivers you could always tell a bad match by a power output indication that never makes it to the top. It would probably be wise to check your VSWR initially with an external meter before pouring on the coal.

Dialing in the VFO mode is a snap. Getting down to the AM aircraft band requires just a couple of button pushes. We found half-microvolt sensitivity from aircraft band all the way up through 170 MHz on VHF, and one-quarter-microvolt sensitivity on UHF band limits, too. We drove the unit through "intermod alley," and it was no worse than other dual-band mobiles we have tried. This is a major improvement over the Alinco 599, which had such a hot receiver that it was prone to intermod. A built-in attenuator of about 20 dB can be placed in either, or both, VHF and UHF bands when you have plenty of signal to work with and you want to knock out intermod. A very small "ATT" icon appears above the frequency display to show the attenuator turned on.

The Alinco DR-610T features 120 memory channels plus split channels, call channels, and scan edge channels. They are divided into five banks. Bank A, B, and C memory channels are used for both VHF or UHF. The same memory channel can be recalled for both VHF and UHF. Thirty channels are dedicated to VHF, 30 channels for UHF, and 20 per Bank A, B, and C (total of 60) can share bands. The shared bank is an advanced feature, and most hams will start off with either VHF or UHF by themselves. To memorize a VFO frequency in a specific memory, you would push the "function" button, then the bank button, then dial up the frequency you want, and push the "MW" button while the function symbol is showing. While this sounds a bit confusing, it begins to make sense after you have programmed a couple of channels. I would say it's no harder to program this set than any of the others, once you read the manual and follow the steps precisely.

We tried the "spectrum analysis" feature, also found on an Alinco handheld, and indeed little LCD bar graphs go up and down as adjacent-channel and on-channel activity come up and go away. But it's not real-time, and there is an annoying "hiccup" each time the unit samples the MPU looking to see what's happening on other frequencies or channels. I would view the spectral display as a specialized feature that only a few hams will truly take advantage of. It's not the same as looking at a spectrum analyzer.

The Alinco goes into single-band transceive easily, eliminating the band you don't want showing on the screen. This is a handy way to make programming easy for you when you're on the road and you're just listening to a single band. When checking repeaters for input activity, you will feel for the second button in on the bottom (the reverse button), and give it a push. While this is a great feature, I wish they had put the reverse button as a double push of the main tuning button.

The CTCSS built-in encoder was straightforward. However, why no decoder? The new little Radio Shack single-band mobile offers both encode and decode. Other manufacturers leave out decode, too, so it'll probably be awhile before we get encode/decode as a built-in feature.

The unit can easily go into the "set mode" to allow the following menu selections: beep tone volume, bell audio on/off, speaker on/off, display back lighting, time-out timer, channel scope receive interval, channel scope kilohertz width, DTMF first-digit delay, DTMF burst and pause interval, LITZ on/off, monitor function on/off, and S-meter squelch on/off.

Crossband capabilities? Yes—a great feature. Unlike earlier models that required internal modification, the new DR-610T has full crossband capabilities. You would only use crossband with the optional CTCSS decoder installed and set. If you don't, random noise could trigger your crossband receiver to unsquelch, causing the transmitter to lock on, and a signal containing nothing but hash to go out on the air. If you only use crossband duplex with CTCSS decode, the only thing that will trigger your transmitter is a proper signal with a proper tone. It would also be good to enable the time-out timer to cycle the whole system down in case something should hang up the transmitter.

If you have the built-in tone decode unit, you can control your transceiver using a DTMF companion hand-held or mobile set. Number 45 starts accepting remote-control commands, and number 54 stops the remote-control commands. D1 turns the crossband repeater on, and D4 turns the repeater off. You can allow direct frequency entry up to five or six digits in the external remote-control mode when working frequencies or memory channels in crossband. We recommend that you contact your local VHF and UHF frequency coordinators before enabling this unit as a base station in the crossband remote.

Packet operation of the Alinco DR-610T can be a normal TNC at 1200 bps, with an input of 2.7k ohms and a normal modulation input of 10 millivolts peak to peak. For 9600 baud, the input is 10k ohms at 2 volts peak to peak with a TNC that can handle this faster rate. The Alinco crew offers several pages on typical packet operation hookups, and we judged the diagrams as very good.

When it comes to group pager modes, selective calling, all calling, and group calling, Alinco has moved well ahead of other manufacturers in providing documentation and explanation in their user manual. Few hams ever use the group pager mode, though it's a very handy feature to alert one person, groups of 10, or groups of 100 that something is happening out there on the airwaves. The pager mode requires the optional tone unit for decoding, but the auto-dial mode that is part of the basic unit allows encoding any tones that you wish to send out. There are seven digits in the total group pager mode. Wild-card tones can alert many stations at the same time of incoming traffic. I suggest that emergency communications team leaders help everyone set up for this very important mode for disaster preparedness. Most sets have this group-call capability with the optional decode chip, and it is indeed a very functional—albeit complicated— operation.

The DR-610T is best suited for small-vehicle use. You would want that detachable head right in front of you, and you may wish to remote-connect the microphone so you can get your big fingers around those very tiny volume and squelch knobs. The tiny buttons and the tiny volume and squelch knobs have almost exceeded the demands of miniaturization for most of our radio users. Several users mentioned that the buttons and knobs were too small for heavy-duty mobile use. However, the DR-610T's performance was extremely impressive when it came to solid power output, cool-running transmitter, and plenty of receive audio for noisy vehicles. The display was relatively small, but very viewable both day and night as it is back-lit.

If United States amateurs embrace LITZ, it will be a boon for travelers, who will be able to signal for help or roadside assistance by simply holding down the zero button while keying the mike for more than three seconds.

Best of all, the new Alinco DR-610T is probably one of the lowest-priced dual-band mobile transceivers, with more than enough features and memory channels than you'll probably ever use. But it's nice to know you have a transceiver that will grow with how you plan to use it. For the best deal, get those internal chips at the same time you purchase your new set. Plug them in, and get set for a power-packed dual-band transceiver that is just as much at home at your base station as it is under the dash or above the rearview mirror in your car. I liked the Alinco DR-610T.

How About a 2W 40m Transceiver Kit?

Build a "fits-in-your-pocket"40m QRP transceiver.

Photo B. The completed rig.

Jeff M. Gold AC4HF
1751 Dry Creek Road
Cookeville TN 38501

Club Project

The Wilderness Radio NorCal 40A was originally a club project of the Northern California QRP club. The club wanted a project that would really spark interest in QRP. Jim Cates WA6GER, Doug Hendricks KI6DS, and Wayne Burdick N6KR, the club's organizers, got together to discuss a possible club project. Their philosophy was that if they could come up with a small QRP CW transceiver that was easy enough for the new builder, yet performed well on the air, they would have a new breed of low power enthusiasts. The word about the new kit spread rapidly in QRP circuits and the newly formed NorCal club grew to over 1,500 members in just over two years. The success and growth of the club can, in a great part, be attributed to the club projects. The club also publishes an excellent magazine called *QRPp*. Bob Dyer KD6VIO recently started Wilderness Radio to offer the NorCal 40 commercially to all those who missed out on the club's offering. Bob is now offering this kit and other excellent NorCal QRP kits.

How QRP Is It?

Wayne Burdick N6KR designed the kit for the club. The NorCal 40 was designed to be a compact 40 meter CW transceiver optimized for portable, battery-powered operation. The rig has very low receive current drain, typically only about 15 mA. It is also very thrifty on transmit. The rig has RIT (receive incremental tuning), very smooth and quiet transmit/receiver switching, a very pleasant sidetone, and the power can be adjusted internally from almost nothing to a maximum of between 1.8 and 3.0 watts, depending upon the supply voltage.

I have had many new hams ask for advice on what type of kit to start with, so I've established some basics that are the key to any successful venture into this area. It should be easy and fun to build. This means the directions have to be clear and easy to follow. The printed circuit board needs to be of high quality and clearly silk-screened so you know which parts go where. I prefer plated-through solder-masked boards. They are much easier to solder: the solder joints are stronger and the solder mask helps eliminate one of the two major building errors that new kit builders frequently run into: putting the wrong part in the wrong place or ending up with a solder bridge on the board. (A solder bridge is where you accidentally get solder to connect two parts of the board that aren't supposed to be connected.) Clear instructions and a good silk-screen help eliminate the wrong part problem and the solder mask helps eliminate the solder bridge problem. The Wilderness Radio kit has a top-of-the-line, nicely silk-screened, plated-through, solder-masked printed circuit board and good instructions.

The next area that new kit builders are concerned with is tuning up the rig. This kit was designed to be easy to align and it can be done with no test equipment. If you don't have test equipment, such as an oscilloscope and frequency counter, you can use an HF transceiver.

VFO-The Way To Go

New builders are usually looking for inexpensive kits. While separate transmitter and receiver kits are available, if new builders don't choose kits that perform well they can easily get discouraged. I always recommend a transceiver over separate transmitter/receiver combinations. I also recommend a superhet receiver with a VFO rather than a crystal-controlled kit. It may be fun for a

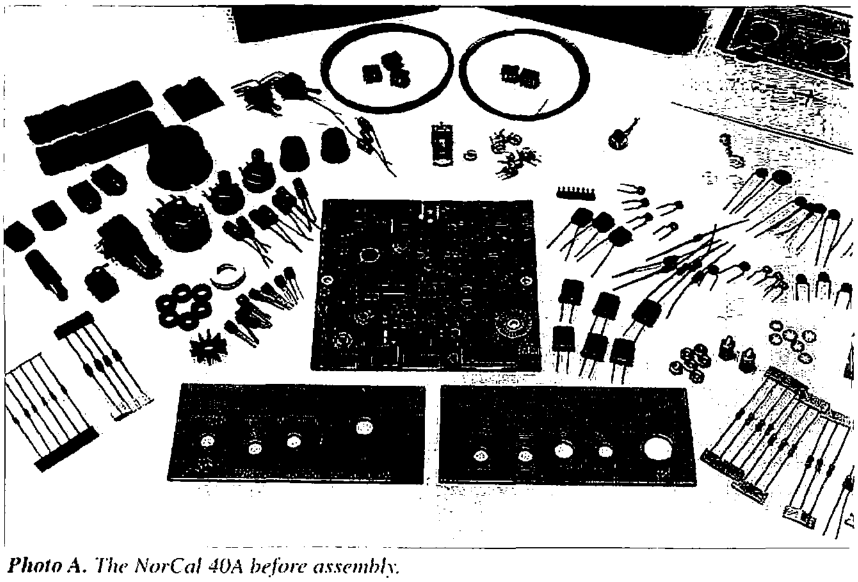

Photo A. The NorCal 40A before assembly.

Continued from page 35

really works! From *Amazing Mind Machines You Can Build*, I have improved my use of the Pendulum and had a lot of fun with it and the Energy Wheel. I then built the Wishing Machine, using the block diagram and a Radio Shack Mini Amplified Speaker #277-1008C as the active circuit. By following the author's suggestions I have helped a good friend who is suffering from prostate cancer. He is taking chemotherapy, but is not experiencing any of the usual illness that is associated with this treatment. His improvement since using the Wishing Machine has been nothing short of fantastic. I have enjoyed studying from these books and plan to add to my library on a regular basis. Keep up the good work. There are many of us who really enjoy your editorials and benefit greatly. Thanks.

You're welcome! But Ken, how about letting me know what books you've found that I might enjoy?... Wayne.)

Richard Harrison KB5WZI. My father-in-law, Phil Rand W1DBM, recently became a Silent Key. Phil was born in 1906, the son of a founder of Remington Rand Corp. He was a registered engineer, inventor and prolific author. For instance, among his WWII contributions was a TV-guided bomb. An avid ham, his first *QST* articles appeared in 1930. He finished his final

Continued on page 61

short while to operate some of these kits, but I found the fun ran out quickly when I was stuck on a single frequency.

The NorCal 40A has a superhet single-signal design receiver which has excellent sensitivity (it hears the signals if they are there), selectivity (it can separate the signals), good audio output, and an AGC circuit (automatic gain control to attenuate very strong signals and keep the audio more constant). The VFO (variable frequency oscillator) is very stable.

Physically, the rig is very small (2.25" H x 4.5" W x 4.5" D). One double-sided, screened, and plated-through PC board is used. There is *no* chassis wiring: All controls and connectors and even the case parts themselves mount directly to the board, resulting in a much easier final building stage. The custom .060 case is extremely rugged and is designed to allow the top and bottom to be removed easily for alignment or testing. Long-life plastic latches are provided on the top so no screwdriver is needed to access internal controls. If you like to play with the tune-up every once in a while, or just show off your work, this is great. The rig is small enough (one of the smallest on the market) to fit easily in a backpack. I power mine with a pair of small gel cells that keep it going for a long time.

After building about every kit on the market, it amazes me that this design was originally a club venture. It was so successful that they had to do multiple runs of the kit, selling them all over the world.

Accessory Keyer/Counter

The Wilderness Radio NorCal 40A is revision B. The AGC performance has been improved. A low-pass filter has been added after the VFO to improve receiver image rejection by 10 dB, and improving the AGC and transmit/receive switching for better attack/delay times and reduced audio thumps. The case has nifty plastic latches and the chassis is supplied in a beautiful blue painted and silk-screened combination. Even though the cabinet is small, there is still room for the more advanced ham to play with added accessories such as small keyers.

One of Burdick's latest kits is also being offered by Wilderness Radio. This is the KC1 keyer/frequency counter. It is a small iambic keyer with 54 bytes of message memory and a displayless frequency counter that reports the frequency in Morse code. There is room

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

It's here! After many months of anticipation, and quite a bit of work behind the scenes, the RTTY Loop Home Page is now available on the World Wide Web. While this column, running in the pages of *73* for more than eighteen years, has reached countless numbers of radio amateurs, the potential audience for the Loop on the Web is virtually unlimited.

To access the RTTY Loop Home Page, point your net browser to: http://www2.ari.net/ajr/rtty/ and the home page will be displayed. Fig.1 shows what you will see:

From the home page, you may jump to a full text of the current column, a listing of the software available in the RTTY Loop Software Collection, a download section for current or special software, and a page of links to other interesting sites. The column text is wired with hyperlinks to mentioned sites, so that clicking on a site's name described in the column will take you to that site. I will also try to make recent software mentioned in the column available for download, through the download section, as well as provide for any more specialized requests, if possible.

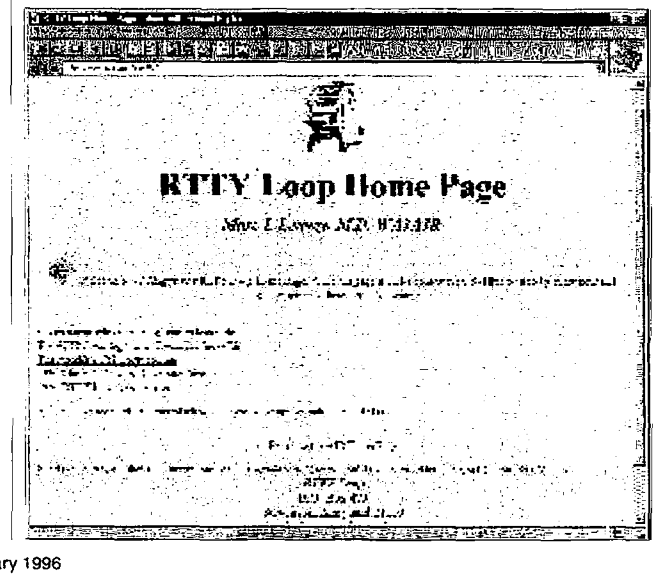
I hope that the RTTY Loop Home Page can be the first home page of an electronic edition of *73*. Let's see what the editors can do with that one!

Along with the new page come new addresses for correspondence. In order to get to your mail in a more timely fashion, I have a new address for the readers of RTTY Loop. Check out the top of the column, and address any snailmail to the P.O. Box. My new Internet address, in conjunction with the home page, is ajr@ari.net — although I continue to maintain accounts on CompuServe and America Online.

I received a note from "RC" KE6BGN, who wrote regarding the sound card article for packet and RTTY. He writes:

"I had a bit of a problem tracking down any of the sound cards that were listed in your article. I was told that of the sound cards you had listed, these were older sound cards and hard to come by. After some hard looking and calling, I found the telephone number of the makers of the Cardinal 16 sound card. They are located in Lancaster, Pa. and their number is: (717) 293-3049. I was told that they are no longer producing this card, but still have some in stock and are letting them go for a mere $60. When I asked them about the software development kit that was mentioned in your article, however, I drew a blank. I will try to find out more on this. This information might be nice to pass on to your readers.

"Also I have a question for you. In the article it said that if you were going to get a sound card to accomplish Packet and RTTY, it had to be based on the PSA standard. During my search, I asked several computer stores what this meant and was only partially answered at one store; that it stood for 'Packet something-or-other.' Needless to say when I heard the word 'packet' from a non-ham, this piqued my curiosity even further. Could you tell me what PSA stands for in relation to sound cards?"



Well, RC, I looked, too, and came up blank. I will assure you that "packet" is anything but an exclusive ham radio term. Most data networks in use today send data in packets, and the protocols in use, one of which is the X.25, often translate into amateur protocols, witness the AX.25 protocol. Good luck on the boards, though, and I will pass along whatever information I discover.

Jack, AAØJB, writes a note via America Online, in which he relates:

"I was reading your article in May 1995 about the program XPKM157 as written by KF7XP for the KAM and I got a copy via AOL and tried it out. Looks good but got a problem. I use COM 3 and IRQ 2 for my TNC. Tried to get the program to initialize but every time I hit the IRQ box my computer locked but good. Had to use the RESET control to get it going again. Would really like to try this program but looks like something is missing.

"Would like to know it KF7XP has a E-mail address. Maybe he knows of the problem and can offer a fix. Also, maybe you know of another place to get the latest download? The one in AOL was several months old. I tried the Internet address in your article but did not find a copy."

Well, Jack, as long as you are using "standard" settings for your COM port, you shouldn't have any problems. The latest copies of the programs can be had on the Internet Direct server, reachable through their web site, http://www.indirect.com, or download the files directly on the ftp site:

ftp://ftp.indirect.com/pub/software/hamradio/xpware. Take a look there, and see if that doesn't help answer your questions.

The Baycom project brought quite a few letters regarding availability of the integrated circuit central to the project. Rev. Greg Schluter, KC5FLI, writes that he obtained the TCM3105 integrated circuit from JDR Microdevices for $8.95. Their toll-free number is (800) 538-5000.

John Kirk, VE6XT, also notes that the chip should be available by mail order from Active Component Sales, as their Canadian parent stocks them. The US 800 number doesn't work in Canada, so he can't verify, but a call to (800) 934-5206 may turn one up. They also claim to stock the rather oddball crystal needed for a very reasonable price.

One last letter this month from Robert Twiggs, WA3YRI, who writes looking for any program for an IBM compatible that will perform RTTY/AMTOR using an AEA-CP1. He currently uses a C64 with AIRDISK and would like to get the thing working with his 486-DX66 PC. He does not have the RS232 option and knows that he will have to use a MAX232 or equivalent circuit to connect to the PC.

Well, Bob, this gives me an excellent opportunity to refer you to the RTTY Loop Software Collection. Several of the packages there may be of help to you, as well as some commercial programs we have mentioned in the column before, such as BMK-MULTY. The easiest way to get a copy of the software list is from the RTTY Loop Home Page but, if you have no web access, drop me a self-addressed, stamped envelope, to the above P.O. Box, please, or send me E-mail at ajr@ari.net on the Internet, or on CompuServe at 75036.2501; or America Online at MarcWA3AJR, and I will be happy to return the list to you. In the meantime, keep on looping, and don't miss the next issue of *73's* "RTTY Loop!"

Staten Island NY 10313-0006

Welcome Aboard!

"Welcome Aboard!" is the official Navy greeting. With it, I was invited to be a guest speaker at the U.S. Naval Academy in Annapolis, Maryland. After my wonderful experience last August, addressing the cadets at the West Point amateur radio club, how could I not visit Navy? I accepted the invitation of Lt. Commander Herb Elkins A3FDO and Midshipman 1/C Trevor Bast KA8ZUO, and I was on my way.

The ride over the Chesapeake Bay Bridge is a real experience. The view of the sun going down over the myriad of boats in the water was simply breathtaking. My tour of the "Yard," which is the traditional name of the Naval Academy's campus, was enlightening and impressive. The architecture is a combination of French Renaissance and contemporary style. The campus has expanded to 338 acres. Monuments throughout the Yard commemorate the bravery and heroism that are an important part of the academy's heritage. Buildings and walkways are named for graduates who have contributed to the naval history and to the nation; graduates such as Admirals Chester Nimitz, William "Bull" Halsey and Hyman Rickover, President Jimmy Carter, and 40 astronauts. The brigade-size student body of 4,000 midshipmen participate in a 140-semester-hour program which incorporates a core curriculum of required courses, plus a choice of 18 major fields of study, a wide variety of elective courses, and advanced study and research opportunities for highly motivated students. Classes are taught by 600 highly qualified faculty members. About half are civilian scholars and half are experienced military officers.

My tour guide for most of the day was Trevor Bast, president of the amateur radio club. It was a pleasure to be in the company of such high caliber students as Trevor. One of the highlights of my day was watching the "formation" for lunch outside Bancroft Hall. It's not often that I get to see 4,000 young men and women line up with such precision. It's even less often that I get to eat lunch with such an outstanding group.

W3ADO

While visiting the ham station, I got to meet with Bob Bruninga WB4APR, who is a retired Navy commander and is the trustee and technical coordinator for the station, W3ADO. While the station I visited was in small quarters back in August, the club plans to move to a larger facility. It may have been tight quarters, but the view of the bay was spectacular.

The amateur radio club is the Naval Academy's oldest extracurricular activity, dating back to 1928. For many years it has provided midshipmen with the opportunity to become licensed, to upgrade their present licenses, to enjoy a relaxing hobby, or to pursue specific technical interests within the hobby. The club station is available to all members at any time. In recent years midshipmen have attempted to communicate via moonbounce, satellite, and packet.

Photo A. *Watching a formation of the brigade was an exciting experience.*

Photo B. *(Left to right) Trevor Bast KA3FDO, president of ARC W3ADO, and Lt. Commander Herb Elkins KA3FDO in the "Model Room," in front of a take-apart generator.*

The club is well equipped for HF communications. They currently use a Kenwood TS-440S and an ICOM IC-701 through a Cushcraft R-5 vertical and a G5RV antenna. Three mobile VHF FM transceivers, two Kenwood TM-251As, and a Kenwood HT give excellent 2 meter capabilities. Two PCs, an MFJ 407B, and an AEA Packratt allow them to operate VHF and HF packet from the station. The many technical resources of the academic departments are often available for the club's use. In the past that avenue has provided them with the use of a satellite dish and all-mode VHF capabilities.

The ever-popular and traditional Army-Navy football game provides the club with a reason to set up a special events station every year. Last year on Saturday, December 2nd, they operated from the stadium in Philadelphia for the duration of the game. The normal routine is to operate SSB in the general portion of 20 and 40 meters.

Last spring, the club had the privilege of operating during a shuttle mission as part of the SAREX program. Club members as well as interested faculty were able to communicate with the astronauts for approximately half an hour. The exchange between the *Atlantis* and the midshipmen included each sending the other a short video presentation. "Yeah, I've got color!" Lt. Col. Cameron said upon receiving the academy's video. "Man, great pictures." The exchange represented the first time that a space shuttle has successfully received video from the ground. Usually it's the astronauts who are sending the pictures.

Later that evening I addressed a group of midshipmen who were considering joining the club and wanted to learn more about ham radio. I can't describe how exciting it was for me to look out at a "sea" of white uniforms in the auditorium. With all the demands put on the midshipmen's time, it was nice to see such a good turnout of students interested in pursuing radio. We spoke about the possibility of my lending assistance to those club members who were considering setting up classes in local schools as part of their community service. Perhaps we can do a follow-up column in "Hams With Class" to let folks know how the project went. The ham radio operators at W3ADO seemed very receptive to the idea of scheduling contacts with younger school children. They are an enthusiastic, bright, and extremely hospitable group of young adults.

Photo C. *The members of the W3ADO ARC were an enthusiastic and hospitable group.*

I thank my hosts for a most enjoyable weekend, and I look forward to some outstanding contacts. 73

HAMSATS

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

Satellites on a String

Ham radio balloon projects are not new, but they are fun, educational, and exciting. They are a lot easier and cheaper to design, build, and launch than satellites. Amateur balloon launches have been used to test ideas for future satellites, like the pre-AMSAT OSCAR 7 tests in West Germany in the early 1970s.

Most of today's amateur radio balloon launches focus on digital and voice communication experiments and amateur television systems. The payloads usually weigh from 4 to 12 pounds and can be sent to altitudes over 90,000 feet with a $40 balloon and another $50 for helium.

"Today's typical balloon can cost $80,000 and have a payload weight of more than 3,000 pounds."

Payloads are designed for light weight and low current consumption. They must also be built to survive near-vacuum and extreme cold. Power is usually provided by sulphur-dioxide lithium batteries, and antennas are typically omnidirectional ground planes or vertical dipoles. Lots of foil is used for shielding, and styrofoam for padding and rigidity. Voltages, currents, and temperature probes are monitored by small dedicated computers that send data to the ground as telemetry.

After a typical ham radio balloon is launched, the communications experiments, either crossband repeaters or packet digipeaters, find many takers. With an altitude of 100,000 feet, the horizon (as seen from the balloon) is 400 miles distant. For a north Texas launch, it is possible for hams in Salina, Kansas, to talk with others in Corpus Christi, Texas, through an appropriately programmed dual-band HT at the balloon. Video cameras with small 1- to 10-watt ATV transmitters have provided spectacular views from 20 miles up.

When the balloon finally achieves maximum altitude, it pops. A direction-finding team is customarily in place to chase the package as it parachutes back to earth. Years ago this was a grueling "foxhunt," since no one knew where the package would land. Computer predictions help, but the final few miles to the crash site are never easy. Today, many groups use Global Positioning System (GPS) receivers on the package, hooked through packet Terminal Node Controllers (TNCs), and VHF or UHF transmitters to broadcast the location of the payload during the flight. It's much easier to simply note coordinates on a map or laptop computer system, and then walk right up to the payload after landing.

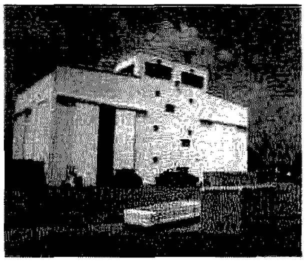

Photo B. One of several buildings at the Palestine, Texas, NSBF facility (Ken Axelson photo).

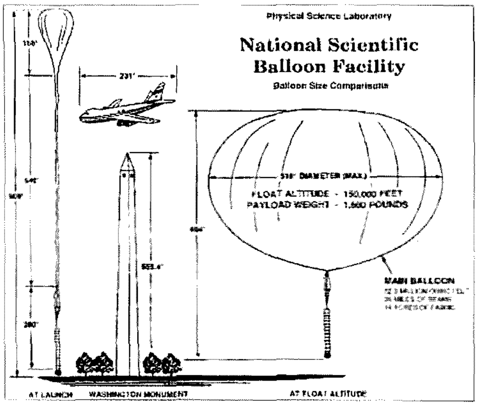

Photo A. Balloon size comparisons (NSBF/NASA drawing).

Three ham radio balloon groups in Texas decided to find out how the "big boys" launch scientific balloons. Members of the South Texas Balloon Launch Team, the North Texas Balloon Project, and the Clear Lake Amateur Radio Club balloon group converged on Palestine, Texas, home of the National Scientific Balloon Facility. These three groups have collectively launched nearly 20 balloon payloads to the edge of space in the last five years.

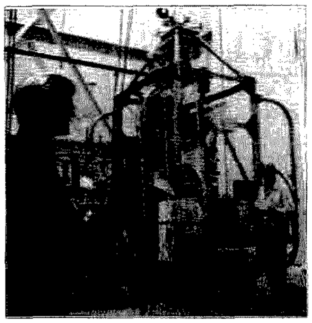

Photo C. Several "serious" payloads are launched from the Palestine location every year. This one was sponsored by educational institutions in California and Italy (Ken Axelson photo).

Go to Buffalo and Head East

Palestine, Texas, is about 180 miles north of Houston and 100 miles south of Dallas, just 36 miles east of Buffalo. This town of 18,000 has been home for the National Scientific Balloon Facility since 1963, when the name was just the Scientific Balloon Facility. Originally aligned with the National Center for Atmospheric Research and the National Science Foundation, the installation is now sponsored by the National Aeronautics and Space Administration (NASA), and operated by the Physical Science Laboratory under the auspices of New Mexico State University of Las Cruces, New Mexico.

The primary goal of the NSBF is to plan and develop facilities and to provide operations to meet the ballooning requirements of the scientific community. The organization also performs research and development to meet future ballooning requirements and provides consulting services in the field of scientific ballooning. It takes a team of 78 engineers and technicians to contribute consulting, helium storage, preflight rigging, launching, tracking, electronic and meteorological support, and payload recovery.

The facility has launched more than 1,700 balloons for 35 universities, 23 other research agencies, and 33 foreign groups. Today the average payload weight is more than 3,000 pounds, with a balloon volume in excess of 28 million cubic feet. Payloads up to 5,000 pounds with 40 million cubic feet of balloon volume are quite common. Top altitudes are usually up to 125,000 feet. A typical balloon may cost $80,000, with $40,000 of helium. It may sound expensive, but it's much cheaper than a typical ...satellite launch.

Payloads cover many types of research, including cosmic-ray studies; gamma-ray, X-ray, optical, infrared, and ultraviolet astronomy; atmospheric sciences; magnetospherics; and micrometeorite particle studies.

Communications gear on the balloon payloads varies from simple to highly sophisticated. For local flights, typical VHF or L-band systems are used for telemetry and control. Long-duration flights, where the payload will travel beyond the horizon, require more complexity. Satellite links through ARGOS, INMARSAT, and NASA's TDRSS are used. The NSBF is involved in multi-day launches from Antarctica which necessitate the satellite links.

The Tour

Dwight Bawcom, manager of the National Scientific Balloon Facility, and Bob Moody K7IRK provided the ham radio balloon groups with a three-hour tour. Dwight began the program with a short talk on the work done at the facility and some videotape footage of various launches from Texas, New Mexico, and Antarctica. It was a great way to get started, since most of those attending were not aware of the tremendous scope of large scientific balloon launches.

Payloads and balloon volumes have increased by a factor

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

As I was walking through the hamfest, I spied a Ten-Tec Century 21 lurking deep inside a rusted-out Escort. Upon first impression, it didn't look too bad. There were the usual scratches on the top, and an odd-looking switch where the "spot" function should be.

Looking the rig over, I half-heartedly said, "What are you asking for the 21?" "Two hundred," was the reply. I returned with the usual hamfest barter: "Well, that's a bit more than I wanted to go."

"Well then, what are you willing to go?"

Thinking I would offer a really silly low price and then meet in the middle, I tossed out, "A hundred bucks." He paused for a few seconds, and I knew he was going to counter my offer with something a little higher. He looked up and said, "Sold!"

Ever since I was dropped on my head as a child, I've been hearing voices. But at this moment, one really loud voice could be heard saying, "Captain, the deflectors just came online!" Of course, being my own captain, I set my own course. Ignoring the warning, I asked, "What's wrong with the rig?"

"Nothing. Works great! Just had it on the air last weekend." This time another voice cried, "Engines are standing by! Let's get out of here!" I ignored this warning as well and plunked my money down.

We returned home, and after we'd unpacked and rested a bit, I proceeded to check out my new toy.

Photo A. The power supply shunt inside the Century 21.

The Century 21

For those who can't remember the Century 21, let me take a few minutes to explain this radio. The Century 21 is a five-band CW-only transceiver. It has an RF power output of about 35-40 watts. Of course, this is quite a bit above the 5 watts normally associated with QRP operation. The Century 21 is powered by an internal power supply, with no means of external 12 VDC operation. You can get around this handicap if necessary, though.

It's surprising that the Century 21 is a multiband *direct conversion* based transceiver and not a superhet design. It is also unusual that the Century 21, with its direct conversion receiver, operates with a built-in AC supply. Direct conversion receivers are noted for their pickup of any nearby AC fields and for the hum they generate.

First Problems

Upon powering up the rig, it became instantly clear things were not exactly up to factory specs. First, the 20 meter band was completely dead. Nothing at all could be heard on this band. The other bands seemed to be working—until I tried to transmit. On 80 meters I had all of 15 watts of output, somewhat less on 40. Twenty meters was dead on transmit, too. Ten meters showed little life, but did move the wattmeter's needle up a bit.

Now, to add salt to the wound, those two voices I had heard at the time I was thinking of getting this rig were jumping up and down yelling, "We told you so! We told you so!"

During testing of the transmitter, the overcurrent protection circuit in the power supply kept shutting down the supply. The meter monitoring RF output never reached the point to cause the supply to shut down. After a few minutes of operation, the supply would hardly run the receiver at full volume. So, problem number one was going to be centered on the power supply and its controls.

To prevent the supply from kicking out, I disabled the main +12 volts to the PA stage (something I would get really good at doing).

The power supply inside the Century 21 is built around a design used by several of the Ten-Tec power supplies. In fact, it's basically the same design used in the power supply I had for my old Triton 4.

The design is a basic full wave bridge rectifier and filter capacitor, with a 723 voltage regulator chip doing all the work. A single pass transistor is mounted on the rear apron of the Century 21. What makes the circuit stand out is the overcurrent shutdown protection.

There is a shunt inserted into the negative lead of the power supply. Since the shunt is really a very low value resistor, a small voltage is generated across it. This voltage is applied to a divider circuit and then sent along to an SCR.

As long as the current flowing through the shunt is within the setting provided by RF, the supply operates normally. However, if a problem occurs, such as excess current to the PA stage, then the SCR will fire, removing drive from the pass transistors and shutting down the power supply. To reset the SCR and the power supply, you must turn off the rig, then power back up. If you did not fix the problem, the supply will again shut down. The process will repeat until the current falls to within the setting of the trip trimmer.

One of the best things about the Century 21 is the wide open spaces between the top and bottom covers. You can really walk right in and have plenty of room to work. Upon closer examination of this unit I could see that I was not the first person to touch soldering iron to power supply! There was clearly some damage on the PC board, and several wires had the insulation melted off. There were too many tacked solder joints to count.

A few checks showed that the bulk of the power supply was in working order. This included the transformer and rectifier/filter. The output pass transistor, as well as the driver transistor, had been replaced by someone else. Ten-Tec does not use NTE solid-state devices and three pounds of thermal grease on its pass transistors. The problem was traced to several failed tacked solder joints and a lifted PC board trace. As the circuit heated, the solder joints opened and upset the voltage divider, setting off the SCR which, in turn, shut down the supply.

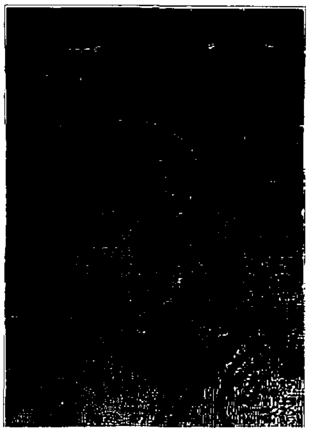

Photo B. Notice the burnt insulation near the terminal strip. The two trimmers on the top of the PC board set the voltage and current trip points for the supply.

Repair consisted of re-soldering all joints and replacing the interconnecting wires between the power supply PC board and the rest of the circuits. The heavy gauge wire to and from the pass transistor was also replaced.

Frying Eggs, Sizzle and Smoke

After putting the power supply back together, I made a quick check; the repairs seemed to be correct. The supply now held on even during receive.

So, with a dummy load and wattmeter attached to the antenna jack, I keyed the unit and attempted to set the RF output with the drive control.

On 80 meters, I had 30+ watts of RF output and 20 watts on 40. I advanced the drive control until it was in its stops and there was still no increase in output power. Then the power supply shut down. Resetting the supply and reducing the drive control again, I attempted to increase drive once more. This time, with the drive control only halfway up, the PA sounded like someone was frying eggs inside. A few seconds later, plumes of smoke started to emerge from the cracks.

After the smoke cleared and the PA cooled down, a look inside revealed that the final transistors, or what remained of them, were history. Now, I wonder if the trouble with the power supply this time (and in the past) was related to the bugs hiding inside the PA?

We'll pick up the pieces and continue next month. 73

CARR'S CORNER

Joseph J. Carr K4IPV
P.O. Box 1099
Falls Church VA 22041

Transmission Lines (A Bunch of 'Em)

Fig. 1 shows several basic types of transmission line. Perhaps the oldest and simplest form is the *parallel line* shown in Fig. 1A. This type of transmission line consists of two identical conductors parallel to each other and separated by a dielectric (i.e. insulator). A familiar example of a parallel transmission line is the "twin-lead" used on many television broadcast receiver antennas. For years the microwave application of parallel lines was limited to educational laboratories, where this type of line is well suited to performing experiments (to about 2 GHz) with simple, low-cost instruments. Today, however, printed circuits and hybrid semiconductor packaging have given parallel lines a new lease on life, if not an overwhelming market presence.

The second form of transmission line, which finds considerable application at microwave frequencies, is *coaxial cable* (Figs. 1B through 1E). This form of line consists of two cylindrical conductors sharing the same axis (hence "co-axial") and separated by a dielectric. For low frequencies (in flexible cables), the dielectric may be polyethylene or polyethylene foam, but at higher frequencies Teflon™ and other materials are used. Also used in some applications are dry air and dry nitrogen.

Several forms of coaxial line are available. Flexible coaxial cable is perhaps the most common form. The outer conductor in this type of cable is made of either braid or foil. Again, television broadcast receiver antennas provide an example of such cable. Another form of flexible or semi-flexible coaxial line is *helical line*, in which the outer conductor is spiral wound. *Hardline* is coaxial cable that uses a thin-wall pipe as the outer conductor. Some hardline coax used at microwave frequencies uses a rigid outer conductor, and a solid dielectric.

Gas-filled line is a special case of hardline which is hollow (Fig. 1C), with the center conductor supported by a series of thin ceramic or Teflon™ insulators. The dielectric is either anhydrous (i.e. dry) nitrogen or some other inert gas.

Some flexible microwave coaxial cable uses a solid "air-articulated" dielectric (Fig. 1D), in which the inner insulator is rigid, rather than continuous around the center conductor. Reduced dielectric loss increases the usefulness of the cable at higher frequencies. Double-shielded coaxial cable (Fig. 1E) provides an extra measure of protection against radiation from the line, and EMI from outside sources, from getting into the system.

A variant that seems to combine the advantages of both parallel and coaxial concepts is shown in Fig. 1F. This form of transmission line is called *shielded parallel line*. As in the parallel line, the two conductors are spaced a certain distance (S) apart and are parallel to each other. In the shielded variety, however, an outer conductor (a shield) is also provided.

Stripline, also called *microstripline* (Fig. 1G), is a form of transmission line used at high UHF and microwave frequencies. The stripline consists of a critically-sized conductor over a ground plane conductor, and separated from it by a dielectric. Some striplines are sandwiched between two ground planes, and are separated from each by a dielectric.

The characteristic impedance for a specific type of line is a function of the conductor size, the conductor spacing, the conductor geometry (see Fig. 1 again) and the dielectric constant of the insulating material used between the conductors. The dielectric constant (n) is equal to the reciprocal of the velocity (squared) of the wave when a specific medium is used:

$$\epsilon = \frac{1}{V^2}$$

Where:

n is the dielectric constant

v is the velocity of the wave in the medium

(Note: for a perfect vacuum, n = 1.000).

a) Parallel Line:

$$Z_o = \frac{276}{\sqrt{\epsilon}} \ \mathrm{LOG} \ \frac{2s}{d}$$

Where:

Zo is the characteristic impedance, in ohms

n is the dielectric constant

S is the center-to-center spacing of the conductors

d is the diameter of the conductors

b) Coaxial Line:

$$Z_o = \frac{138}{\sqrt{\epsilon}} \ \mathrm{LOG} \ \frac{D}{d}$$

Where:

D is the diameter of the outer conductor

d is the diameter of the inner conductor

c) Shielded Parallel Line:

$$Z_o = \frac{276}{\sqrt{\epsilon}} \ \mathrm{LOG} \left(2A \times \frac{1-B^2}{1+B^2}\right)$$

Where:

A = s/d

B = s/D

d) Stripline:

$$Z_o = \frac{377}{\sqrt{\epsilon}} \ \frac{T}{W}$$

Where:

nt is the relative dielectric constant of the printed wiring board (PWB)

T is the thickness of the printed wiring board

W is the width of the stripline conductor

The relative dielectric constant (nt) used above differs from the normal dielectric constant of the material used in the PWB. The relative and normal dielectric constants move closer together for larger values of the ratio W/T.

In practical situations we usually don't need to calculate the characteristic impedance of a stripline, but rather design the line to fit a specific system impedance (e.g. 50 ohms). We can make some selection choices of printed circuit material (hence dielectric constant) and thickness, but even these are usually limited in practice by the availability of standardized boards. Thus, stripline *width* is the variable parameter.

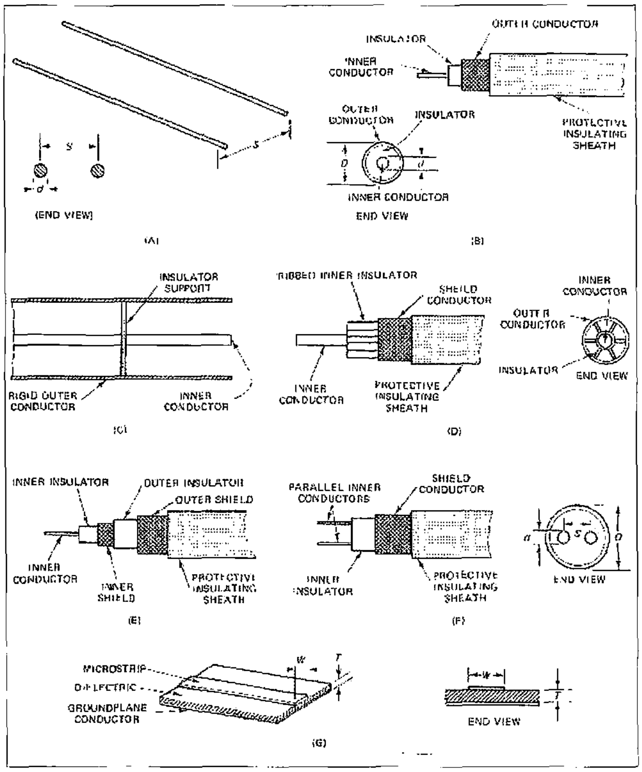

Fig. 1. Types of transmission line.

Equation 5 can be rearranged to the form:

$$W = \frac{377T}{Z_o \cdot \epsilon}$$

The 50-ohm impedance is accepted as standard for RF systems, except in the cable TV industry. The reason is that power handling ability and low-loss operation don't occur at the same characteristic impedance. For coaxial cables, for example, the maximum power handling ability occurs at 30 ohms, while the lowest loss occurs at 77 ohms; 50 ohms is therefore a reasonable trade-off between the two points. In the cable TV industry, however, the RF power levels are minuscule, but lines are long. The trade-off for TV is to use 75 ohms as the standard system impedance in order to take advantage of the reduced attenuation factor.

Velocity Factor

In the discussion preceding this section we discovered that the velocity of the wave or signal in the transmission line is less than the free-space velocity, i.e. less than the speed of light. The velocity is related to the dielectric constant of the insulating material that separates the conductors in the transmission line. Velocity factor (v) is usually specified as a decimal fraction of c, the speed of light (3×10^8 m/s). For example, if the velocity factor of a transmission line is rated at "0.66," then the velocity of the wave is 0.66c, or $(0.66)(3 \times 10^8 \text{ m/s}) = 1.98 \times 10^8$ m/s.

Velocity factor becomes important when designing things like transmission line transformers, or any other device in which the length of the line is important. In most cases, the transmission line length is specified in terms of *electrical length,* which can be either an angular measurement (e.g. 180 degrees or 9 radians), or a relative measure keyed to wavelength (e.g. one-half wavelength, which is the same as 180-degrees). The *physical length* of the line is longer than the equivalent electrical length. For example, let's consider a 1-GHz half-wavelength transmission line.

A rule of thumb tells us that the length of a wave (in meters) in free space is 0.30/F, where frequency (F) is expressed in gigahertz; therefore, a half-wavelength line is 0.15/F. At 1 GHz, the line must be 0.15 meters/1 GHz, or 0.15 meters. If the velocity factor is 0.80, then the *physical length* of the transmission line that will achieve the desired *electrical length* is [(0.15 meters)(v)]/F = [(0.15 meters)(0.80)]/1 GHz = 0.12 meters. The derivation of the "rule of thumb" is left as an exercise for the student. (Hint: It comes from the relationship between wavelength, frequency and velocity of propagation for any form of wave.)

There are certain practical considerations regarding the velocity factor that result from the fact that the physical and electrical lengths are not equal. For example, in a certain type of phased array antenna design radiating elements are spaced a half-wavelength apart, and must be fed 180-degrees (half-wave) out of phase with each other. The simplest interconnect is to use a half-wave transmission line between the 0-degree element and the 180-degree element. According to the standard wisdom, the transmission line will create the 180-degree phase delay required for the correct operation of the antenna. Unfortunately, because of the velocity factor the physical length for a one-half electrical wavelength cable is shorter than the free-space half-wave distance between elements. In other words, the cable will be too short to reach between radiating elements by the amount of the velocity factor!

Clearly, velocity factor is a topic that must be understood before transmission lines can be used in practical situations. Table 1 shows the velocity factors for several types of popular transmission line.

Transmission Line Noise

Transmission lines are capable of generating noise and spurious voltages that are seen by the system as valid signals. Several such sources exist. One source is coupling between noise currents flowing in the outer conductor and the inner conductor. Such currents are induced by nearby electromagnetic interference and other sources (e.g. connection to a noisy ground plane). Although coaxial design reduces noise pickup, compared to parallel line, the potential for EMI exists. Selecting high-grade line, with a high degree of shielding, reduces the problem.

Another source of noise is thermal noises in the resistances and conductances. This type of noise is proportional to resistance and temperature.

There is also noise created by mechanical movement of the cable. One species results from movement of the dielectric against the two conductors. This form of noise is caused by electrostatic discharges in much the same manner as the spark created by rubbing a piece of plastic against woolen cloth.

A second species of mechanically-generated noise is piezoelectricity in the dielectric. Although more common in cheap cables, you should be aware of it. Mechanical deformation of the dielectric causes electrical potentials to be generated.

Both species of mechanically-generated noise can be reduced or eliminated by proper mounting of the cable. Although rarely a problem at lower frequencies, such noise can be significant at microwave frequencies when signals are low. 73

Type of Line	Z_o (ohms)	Vel. Factor (v)
1/2-in. TV Parallel	300	0.95 Line (Air Dielectric)
1-in. TV Parallel	450	0.95 Line (Air Dielectric)
TV Twin-Lead	300	0.82
UHF TV Twin-Lead	300	0.80
Polyethylene Coaxial	*	0.66 Cable
Polyethylene Foam	*	0.79 Coaxial Cable
Air-Space Polyethylene	*	0.86 Foam Coaxial Cable
Teflon™	*	0.70

Table 1. Transmission Line Characteristics

Every Ham's Average

Continued from page 44

value on FM. FSK or other modes where output power is essentially constant.

This article refers to "Average/Peak" reading, because this terminology is normally the accepted wording, although it is not strictly true. The average power of a sine wave is about 63% of peak power, while root-mean-square (rms) of a sine wave is 70.7% of peak value. The rms value of a sine wave delivering power to a non-reflective load is the exact equivalent of a DC voltage of the same value as the rms value when delivering power to a resistive load. This instrument actually indicates rms power levels, which are somewhat higher than average power would be, and therefore are more accurate in indicating the *really effective power* being transmitted. Although I wanted to call the article "RMS/Peak" power, I felt the apparently unusual use of the term "rms" might be confusing, so I bowed to convention and am describing here what is actually happening in this instrument.

Although this RF wattmeter is intended to be left in the coax line between the transmitter and its load, whether dummy, antenna or antenna tuner, you may notice that the output power indicated when using a tuner may differ somewhat from that observed into a 50-ohm dummy load, even though the SWR indicates a 1:1 ratio. There are a couple of reasons for this. First, not all dummy loads are exactly 50 ohms—mine is 51.6 ohms. Second, the output impedance of a transmitter varies with the output level and the operating voltage supplied to the power transistors in the final amplifier stage. The actual output

Niles IL 60714-3108

Your Input

I'll begin this month by saying a hearty "thanks" to all who have been sending in their suggestions, modifications, tips, techniques, and favorite easy-to-build circuits. The amount and the quality of input has been very gratifying and if it keeps up as it has been, the column will indeed go on for a very long time to come. This tells Uncle Wayne that it's a needed addition to *73* and encourages me to put even more of your ideas to work via these pages. So keep those ideas coming in; we can never have too many.

Let me just take a moment to outline once again what I'm looking for in the way of ideas. Basically, anything that will help your fellow hams; tips, suggestions or shortcuts are fair game. Things that you've discovered that perhaps you wish you had known about earlier in your own ham radio career are always helpful. The idea can be technical in nature, an operational shortcut or convenience, a new use for a tool that has ham radio applications, or an innovative way of doing something that might otherwise be a real chore. Equipment modifications are sometimes worthwhile, but please make sure that you've thoroughly tested the mod, that it's not going to cause any unwanted side effects, and that it's easily reproducible by others with the same piece of gear—not just a fluke. It's impossible for me to test each idea, especially if it involves an item of equipment that I don't own, so be completely sure that there are no "gotchas" hidden away.

Also, I'm not looking for extremely complex circuits or new and involved concepts; they're best left for full-length articles, or perhaps a doctoral thesis. I'd prefer ideas that can be understood and implemented fairly quickly by all of our readers, ideas encompassing just two or three paragraphs of column space. That allows for more ideas to be published per month, since there are obviously limitations on space within each issue. I'd like to see "Ham To Ham" eventually be the first column read by *73* subscribers...after Uncle Wayne's editorial, of course! The greatest compliment to the contributors will be when a number of readers begin to make a file of the tips and suggestions published here, saving them for future reference. That's pretty much our current goal; let me know whether or not that corresponds with the direction that you'd like to see the column take.

Please don't send me ideas that have been submitted elsewhere and are still pending acceptance by other publications, or ones that have been previously published. Only new, original, unpublished ideas are usable.

I'll try my best to respond as quickly as possible to each legitimate idea sent to me, since I'm sure that you'll want to know if it's what we're looking for. So far, the vast majority of submissions have been right on the mark of what we're intending for the column. This is your column, echoing your ideas and technical suggestions, to make our hobby more fun for each of us.

Photo A. Paul KBØSJX with his HF vertical in the "resting" position, hung from the wooden fence alongside his house...and out of his neighbors' sight.

Putting "Sparkle" Back Into Your Ham Gear

Probably nothing looks less impressive to "visiting dignitaries" than dusty, dingy-looking equipment in your ham shack. You can put that new-look sparkle back into almost any piece of gear by simply applying a small amount of Armor All Protectant® to the equipment's exterior surfaces with a small cotton ball. It comes in both glossy-finish and dull-finish; it's quick and the results are impressive.

"Power-Up" Message Idea

From Bruce Tennant KE6PZW, Box 7325, Long Beach CA 90807-0325: Since some of the newer handie-talkies offer a programmable, customized message upon power-up, here's a tip that might save some grief for your repeater group, as well as enable a stolen HT to be returned to its rightful owner.

The manufacturers of these HTs suggest in their manuals that the owner's name and callsign be programmed into this "power-up message," but by doing that, you may be playing right into the hands of an illegal user. How? Well, should your HT fall into the wrong hands, especially those of a non-ham, then not only would they have your HT, but immediately upon powering it up, they would have your callsign too! The temptation for such unscrupulous thieves to use not just your HT but your call as well may be just too great.

My tip would be: Don't program in your name or call; use your driver's license number or other form of state identification that could possibly place your HT back into your hands should the police or other agency find it as part of the loot of a captured thief. Law enforcement officials have suggested engraving a driver's license number, along with the state's initials (such as CA for California), into valuables for years now. State and local police have access to the legitimate holders of these numbers and have been able to return stolen goods to many people by this method. Another plus is that an unauthorized user probably wouldn't have the sophistication (or the manual to tell him how) to delete your power-up message from the HT's memory, and it might make him more reluctant to use or sell it.

Note: Excellent suggestion, Bruce. Perhaps the manufacturers should market the feature in this manner, i.e. as an anti-theft "plus." It also makes us all think twice about putting our calls on our portable or mobile equipment in any form. A driver's license number would be a much better thing to use, whether it's in electronic form or otherwise.

A Sticky Subject

In case you haven't tried it, a good all-purpose adhesive is Weldbond®. It's made in Canada and is available in the U.S. in craft and hobby stores. There are many uses for this product in our ham-radio construction and repair "adventures," so you may already be familiar with this adhesive. A nice feature is that the bond remains slightly flexible when cured, which in my experience has better impact resistance than adhesives that become hard and brittle after curing or with age.

Now You See It...Now You Don't!

From Bryon "Paul" Veal KBØSJX, 5855 E. 124th Way, Brighton CO 80601: Living in an area with a homeowner's covenant banning permanent outdoor antenna structures, and wanting to operate 10 meters with my new Tech-plus license, while honing my CW skills on 40 meter CW in preparation for the General exam, I was faced with a not-so-unusual modern dilemma...how to accomplish all of that while keeping a low profile with the homeowners' association sleuths! Here's hoping that my answer may help other hams in similar situations.

I purchased a multiband 1/4-wave vertical that I felt had a good reputation for ease of installation and use. My plan? To mount the antenna temporarily on a permanently-installed pipe that extends out of the ground

I could go on for hours. But, all the "old-timers" will get the point, and all the "newcomers" will scratch their heads. However, it is nice to take a nostalgic look and just remember.

The Icom 706
Continued from page 40

processors, synthesizers, and memory, and this equates to current drain. The receiver draws 1.5 amps all the time. I measured the total current drain at various power levels at 160 meters and 6 meters. The results are shown in Table 1.

Power consumption is important to me because I use a Ten-Tec 938 switching power supply for portable operation. The cooling fan is always running. It is not noticeable on receive, but it comes on full power whenever you transmit and is noticeable. However, this is understandable, considering the size of the radio and the fact that you are trying to dissipate 176 watts(!) keydown (20A X 13.8V - 100 watts); a good cooling fan is needed. I got used to the fan quickly, and it is really not a problem when you are talking.

There are so many features to this radio that I can't possibly cover them all, but I do have to mention a couple of other neat ones. One of these is the "band scope." With this you can sweep the band and paint a picture of signals on the display very similar to a spectrum analyzer! This is really great for monitoring quiet bands for signals (like 17 meters). Another neat feature is that you can get a display of the IF filter passband which moves right and left as you tune the IF shift!

No rig is perfect, but the IC-706 sure comes close! Now, maybe the Icom engineers or a hacker can figure out how to permit crossband operation so we can operate through some satellites, such as the 15-to-10 meter RS-12, with it.

I like the IC-706. It has virtually all the features you need for base and mobile! Finally, it is user-friendly and works great. Icom definitely has a winner here! I more than got my money's worth with this beaut!

A Hot, Selective 2m Receiver
Continued from page 38

All of this fits easily on the 4" x 3.5" circuit board, making it easy to build the R-100 into a small housing or existing cabinet.

You may be thinking that the R100 sounds like just the ticket—commercial quality, great specs, and a very reasonable price. But the thought of actually putting a whole receiver together from a kit is a little scary. Is not to worry. In the first place, the R-100 uses an IC for the entire IF/Detector/Squelch section, which keeps the overall parts count low. A second IC is used for the audio amplifier section, and five more transistors make up the total active device count. Second, the instruction manual is quite explicit, the parts are well-marked, and the double-sided plated-through PC board makes the soldering easy. And third, well, if the unthinkable should happen, there is an in-depth troubleshooting section that should lead you to the source of the problem. The R-100 can probably be assembled in a few casual evenings, or in one night if you're an experienced (or highly motivated) builder.

In any case, the R-100 is probably not an ideal first-timer kit, but it would certainly qualify as suitable for an intermediate builder. As usual, the Hamtronics manual doesn't stop simply with construction details. Tips are given on how to mount the receiver, how to connect antennas, how to use the R-100 in a repeater, how to add a discriminator meter and S-meter, and even how to hook up subaudible tone decoders. Once built, you'll need a high-impedance voltmeter and a signal generator for alignment—both pieces of equipment are usually available through some member of your ham club if you don't have them already. (One thing you'll need that you may not have, and Hamtronics doesn't give you, is a set of tuning tools for the square-holed slugs in the coils. You can order one at the same time you order the radio.)

Whether you use the R-100 as a monitor receiver for the local repeater, a dedicated RF link, or as the receiver in a 2m repeater, you'll find it to be rock-solid, even in heavy RF environments. The R-100 is available in kit form, or fully assembled. Crystals are optional, and are available from Hamtronics, Inc.

Ham to Ham

Continued from page 58

about three feet and into the ground about five feet. The manufacturer's recommended ground radial system was also installed beneath the sod and securely connected to the same pipe, along with a 14-foot commercial-grade ground rod. The need for a good grounding and radial system for any 1/4-wave vertical antenna installation cannot be over-stressed. The outside diameter of this ground pipe is such that the antenna easily slips right down over it, rests on a ring clamp, tightens with a second clamp, and provides a sturdy support for the remainder of the antenna for the time it will actually be up in the air. Remember, it doesn't stay up at all times, only when I want to operate for a while.

The coax back to the indoor radio room in my home is buried beneath the turf about four to six inches, both for protection against damage and for appearance purposes. Make sure that the coax you use is rated for underground applications and that the outer jacket is free of any nicks that might allow moisture into the shield of the inner cable. A quick-disconnect fitting on the coax itself completes the job, but remember to protect this fitting from direct exposure to the weather when not in use.

Photo B. KBØSJX positioning his antenna so that it may be dropped over a pipe driven into the ground at the rear of his fenced-in property. The coaxial cable from his shack meets up with the antenna and the "instant antenna-raising ceremony" is complete.

My "temporary" antenna mount is in back by my property's rear wooden fence, so when my operating time is over, I can simply disconnect the coax, loosen the bottom clamp, lift off the antenna, and hang it from supports attached to the fence itself. The operation takes only a minute or two. The antenna alone is very light in weight, about the same as a heavy-duty deep sea fishing pole...including the bait! The "stored" length along the fence is 18 feet in my case. The photos give you a much better idea of the arrangement that I'm describing. The entire scheme is virtually invisible to the association sleuths for the 90% of the time that I'm off-the-air.

Note: Paul has a nice arrangement here, with possibilities for others in similar circumstances. Photos A and B tell the story best. A hinge-and-lock arrangement might also be helpful (for us older folk) so that the antenna could be "walked" up and down instead of lifted into place, yet it could still be hidden behind the fence when resting in the horizontal position. Such an arrangement might also be used with some of the popular half-wave verticals using a similar design. Lots of "custom" possibilities here; thanks, Paul. By the way, Paul wrote to tell me that he did receive his General...congratulations!

"Green" Is Good!

Here's another tip about an interesting product that's available at most local hobby shops, called Squadron Green Putty®. It's a very quick-drying filler that can be used around the ham shack to fill unwanted holes in panels or cases, or to make a chip or crack virtually disappear in a plastic front panel escutcheon.

That's all for this month. Please keep the ideas rolling in to the address shown in the masthead. And remember, this is your column, where all of the ideas are from one ham to another, which is always the best way! And it doesn't matter how long you've been in the hobby—Paul KBØSJX has been licensed less than one year, yet he saw a workable solution to an common problem. Let's hear from you next month!

Note: The ideas and suggestions contributed to this column by its readers have not necessarily been tested and thus no guarantee of operational success is implied. Always use your own best judgment before modifying any electronic item from the original equipment manufacturer's specifications. No responsibility is implied for any equipment damage or malfunction resulting from information supplied in this column.

Please send all correspondence relating to this column to "Ham To Ham," c/o Dave Miller NZ9E, 7462 Lawler Avenue, Niles, IL 60714-3108, USA. All contributions used in this column will be reimbursed by a contributor's fee of $10, which includes its exclusive use by *73*. I will attempt to respond to all legitimate contributors' ideas in a timely manner, but be sure to send all specific questions on any particular tip to the originator of the idea, not to me or *73*.

Every Ham's Average

Continued from page 57

impedance of a solid-state transmitter will very seldom be exactly 50 ohms, although at its rated output power it will be very close.

The problem lies in the fact that the collector impedance of the final amplifier in a solid-state transmitter is very low—about 1.9 ohms for a 100-watt output transmitter operating on 13.8 VDC. To provide a nominal 50-ohm output impedance requires a step-up output transformer which can have only a finite number of turns on each winding. In the case of the 100-watt transmitter the step-up transformer has to transform 1.9 ohms to 50 ohms, or close to it. The transformer requires a 1:25 impedance step-up, from 1.9 ohms to 47.5 ohms. The turns ratio, which is the square root of the required impedance ratio, is therefore 1:5. Because there can be no partial turns on a transformer, there is no way to produce an exactly 50-ohm output impedance with a transmitter producing 100 watts and operating at 13.8 VDC on the final collectors. So, while the indicated power output may differ from that observed into exactly 50 ohms resistive, it isn't anything to be concerned about.

An entirely different thing occurs when this 100-watt transmitter has its output power reduced to 5 watts to operate QRP, which hams do occasionally. With the DC voltage remaining at 13.8 volts, the collector impedance has changed to 19 ohms! The same step-up output transformer with a 1:25 step-up ratio now transforms the 19-ohm collector impedance to about 475 ohms! Although most antenna tuners can match the input to the transmitter output for an SWR of 1:1 or close to it, the wattmeter between the transmitter and antenna tuner is now looking at a 475-ohm load instead of the 50 ohms it is designed for. Thus, the power output indication may, therefore, be in error.

In all cases you should adjust your transmitter to the power output desired into a 50-ohm dummy load, especially at QRPp and QRP levels. Then, regardless of the indications on the RF wattmeter when operating into a load other than 50 ohms, the power output will either be the same or slightly less as long as the SWR is 1:1 or close to it. For all practical cases, consider your power output to be the same as that measured into your dummy load. The ham at the distant station you're in QSO with won't care.

Mounting and Pointing Lasers

This month I thought I would try to make a big red splash and cover HeNe lasers. For most of us the HeNe or helium-neon laser is just a red glow at the supermarket checkout counter. It's the light source for the price scanner. In some units this could be a diode laser or a tube-type laser. Both of these units emit a bright red beam that is characteristic of a helium-neon (HeNe for short) laser.

The HeNe laser is available in surplus mostly in the 5 to 10 mW power range. Most are used in price checkout stands, laser printers or the older very large industrial printers and some copy machines. Recently we salvaged some lasers by removing them from these types of devices. They were 10 mW laser power heads with focusing optics mirrors and Brag cells. These accessories were used to focus and position the laser beam. The Brag cell is a polished crystalline square structure of lithium niobate. It is this crystal structure through which the laser beam is passed. The cell has two electroplated sets of contacts through which RF energy drives the crystal structure. This drive on the cell structure causes the beam to vary or react to the modulated RF imposed on it (100 mW of power at a frequency of 60 to 90 MHz is normally used). The Brag cell was used to modulate the laser beam for use in printers. Lasers are classified as Type I, Type II, or Type III. The 10 mW laser is a Type III high-power laser and should be used with caution. It carries warnings concerning safety and eye protection.

For safety's sake never look into a laser beam.

Why do we want to use a HeNe for amateur purposes? Well, most things obtained from minimal-budget scrounging-and-foraging missions in commercial and industrial junkyards allow us to have fun with ever-varying surplus electronics that can be quite sophisticated and still inexpensive. By taking advantage of good deals in surplus scrap you can save big compared to buying from your local surplus dealer.

In with the surplus lasers obtained in one batch was a Brag cell laser modulator. The laser, together with the Brag cell modulator, was the mechanism that transferred data to the laser and then to a printed page, in accordance with the printing instructions set. I am not sure just what the original material was, but in any case, as amateurs it is not too important that we know just how a laser printer or copier functions but rather how we can adapt these components to our use.

Most items discarded by commercial industry have a defect of some sort making them unusable to the company. These defects can be overlooked if the device can be made to function in some other-than-normal manner that is still safe and functional.

The remaining metal mount for the laser looked quite bad, but with all the optics still intact with the Brag cell, I decided to use it for my basic laser mount as it was sturdy and allowed some adjustment for laser position.

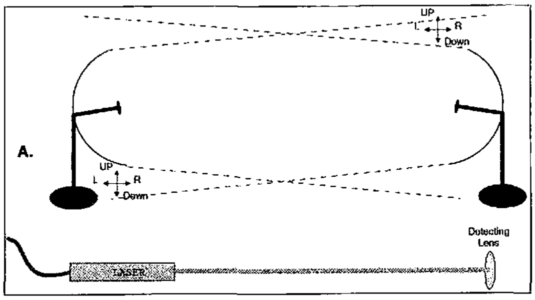

Fig. 1. Comparison between laser and microwave systems and their aiming/directional differences.

This mount had a very fine rack-and-pinion that could be used to adjust the laser mounting in respect to the optics. In addition to the rack-and-pinion there was a two-stage ring mount that held another (smashed) glass laser. Now if you are not into weird science and lasers and optics these parts might not excite you. However, if you intend to do any communication with lasers, the need to point with pinpoint accuracy is quite important and the mechanical considerations just as serious.

Electronics in general is my primary interest, delving into which I have expended a great deal of energy and effort. However, mechanical considerations have always left me in the dust, as my primary tools in the early days were a hand drill and a good set of hole punches, with an assortment of files to do the rest of the dirty work. Remember cutting out a meter hole by drilling the perimeter with about 40 small holes and then breaking it out and filing to fit? Well, these techniques don't work with optics; you don't have that tolerance for error.

En Garde!

Take for instance the pointing of a laser at a particular spot. If it's a blackboard or some similar target in the same room you are, this is a simple task. When the distance increases substantially, say, several miles, the pointing becomes quite acute. It's kind of like fencing with a pinpoint sword several miles long. A very small movement at the wrist produces a gigantic movement at the opposite end of the sword. With a laser the scenario is identical. The ability to point with micro-control accuracy is quite important in the mount.

The aiming operation is just the opposite of a microwave dish antenna where dish diameters are in the 30-inch to larger dimensions. Both lasers and microwaves can use gun sighting optics for sighting-in distant objects that track with the main dish or laser beam. At this point some small micro movement is required to acquire the distant object.

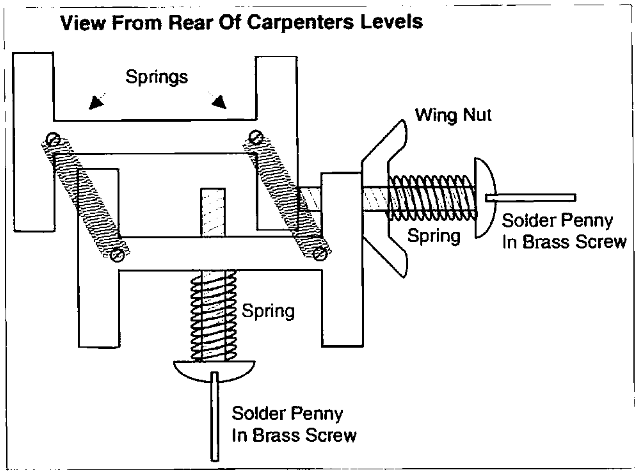

Fig. 2. End section drawing of a laser two-screw positioning mount using two metal carpenter levels.

With lasers it would be to "Drop the spot on the distant detector," and with microwave it would be to "Rock and Lock" one end while the other end reports on the progress of the opposite's moment in signal strength. In the microwave instance, each end of the path can make fine adjustments based on signal strength to each other. By making several of these small angle alignment corrections to the dish orientation at each end of the path several times, you rock the antenna orientation in to each other eventually. See Fig. 1 for aiming concept.

For optical systems, pointing a laser at a target is not quite as simple as in a microwave system. In a laser system, one end must first scan the target to remove errors in point angle, and when the opposite end receives the laser beam of light as detected by its optical receiver, you might be in reverse alignment. That is, the previous receiving station might have good-enough alignment between its receiving optics and transmitting laser to be on (or somewhat close to) transmitting alignment at this time.

In any case, one end must first acquire the other end and then a two-way communications path can be established. Ideally, either end's laser is in alignment with the receiving mechanism, and both are parallel to an exact degree. In the real world some small adjustment is necessary. If the distance is extreme, say, fifty miles versus five miles, then a whole new stance must be taken into account.

At five miles, the typical laser beam diverges or spreads out from a very small spot to one that is about five feet in diameter. This makes it a little easier to point but, still, at even this distance it's not shooting fish in a barrel. There can't be any wobble in the cog here! If you think that hand-pointing a laser will do the trick at paths of a few miles, you need some rethinking. N6IZW and I tried this first-cut "simple" path quite some time ago and found that, with adjustable tripods and with pointer sighting (direct view) to the target, it was not as easy as you would imagine.

The tripod we were using is the same one that is normally used for microwave communications with a large-aperture dish antenna. This microwave conglomeration worked out quite well: signals were so loud that even when the antennas were not pointing correctly we were able to make contact. Pointing the laser using the same tripod showed that a far more accurate pointing mechanism was needed to accurately point a laser at a target. The microwave alignment took about two minutes and the laser pointing took an hour for one-way tests.

The microwave dish pointing arrangements worked well for microwave but were just not capable of the finer resolution needed to aim the laser beam properly at the target. True, we finally succeeded but with lots of effort and meticulous pointing adjustments continuously being made at the laser end of the path. To bring home this point, examine a yardstick lashed securely in the middle (18-inch point) to a good heavy tripod. Now imagine tapping one end ever so lightly with a pencil point and watch the effect on the other end. With a stick or laser beam five or even fifty miles long you're looking at a movement like a freight train passing by. The basic mount has to be very sturdy and some magnitude sturdier than a very good microwave tripod. In a 50-mile laser contact, I would suggest using a metal lathe table as the optical bench stand.

For contacts in the five-mile range, simpler equipment can be employed. The basic microwave tripod can be used for basic pointing. Then the mount attached to the tripod base that houses the laser and rifle spotting scope and receiving photo detector must all be capable of individual fine adjustment. This adjustment scheme is independent of the tripod adjustments. The finer-adjustment mechanism needs to address vertical- and horizontal- position movement. I would suggest looking for something to which a very fine-pitched screw or micrometer can be attached, to handle the final pointing attitude adjustment. See Fig. 2, which covers the two-screw adjustment technique.

In its simplest form a fine-pitched screw can be used with a counter spring in both the vertical and horizontal planes. The counter springs are used to load the screw properly to prevent backlash movement. What type of screw is best? Well, any one with fine threads will work but the finer the better. What I would suggest using would be something that would mimic a commercial micrometer shaft and dial mechanism, or using two inexpensive micrometers themselves may be the best choice. Check out old WWII microwave generators for klystron tubes, as some had micrometers attached to them for tuning. If you decide to purchase them new, hold on to your hat—they cost $50 to $60 each.

I would prefer to try swap meets to locate old worn or used micrometers, even when too worn for industrial use. We want their fine-threaded mechanism for position accuracy, not measurement. In any event, exactly what you use is not important. Just use a device or screw that has a fine-pitch thread, allowing you a fine movement as the screw is turned against its stop.

I have seen two metal levels used for the laser table mount, with one end fixed and the other end with the vertical/horizontal screws and springs for position control. It's simple and quite inexpensive for experimentation, constructed from two wide "H" frame aluminum levels. One level is set on top of the first level, off-set by the "H" frame. See figure 3 for the end view of the two levels. So much for the mount. What types of lasers are available in the surplus market?

The typical Helium Neon (HeNe) laser comes in two styles: a glass tube, and a "head." The basic laser is a glass tube with suitable mirrors on either end and high-voltage clips to attach to the tube for connection to the power supply. When this glass tube is enclosed within a metal container it is called a "head." The glass-tube laser and its high-voltage connections are protected by the metal tube. Usually the high-voltage is tied common to the metal tube as a system ground. Because of voltage in the 1000 or more volts needed to operate lasers, be very cautious and use proper grounding techniques.

There does not appear to be any method of determining what power a laser is by just looking at the device. However a 10-mW unit can be generally regarded as larger in comparison to a 1-mW unit from the same manufacturer. Most of the 10-mW units that I have been able to pick up in surplus are about 16 to 18 inches long and 1-3/4 inch in diameter. They come with a shutter for the laser output end and a shielded cable for power supply connections.

Don't short-circuit yourself: remove the cable connector. It's a special high-voltage connector that is polarized, allowing the proper potentials to be applied to the laser head. Additionally, by being polarized it maintains system ground to the laser head tube.

Welcome Newcomers

Join the ARRA

Wayne Green W2NSD/1

You've been nominated to be a member of the ARRA. So what's the ARRA, a new national ham group? Yep, one with no officers to sit in high places and look down benevolently on us peons, no directors to pass on the pronouncements from the officers, no dues you can't afford, and not even any bylaws to keep out the unwelcome. It's the Amateur Radio Rescue Association, so try as best you can not to confuse it with the ARRL, a Morse code radio relaying group.

Your sole duties, if you sign up as a member of the ARRA, will be to get on the local repeaters and do your best to convince the no-coders that there really is life below 144 MHz. We've got to somehow convince these guys to go for their General tickets...to rescue them from their lonely outpost on 2m. Get those hermits out of their caves and into our ham society. Just think, they may even be missing those endless self-promoting sermons from K1MAN!

When I saw the FCC figures showing the license figures for the last 10 years (see page 65 last month for the bad news), and I saw that despite the explosion of Techs there had been not even the slightest budge in the growth of the higher class licenses, I knew (a) that my efforts with *Radio Fun* to get Techs to upgrade had totally failed, and (b) that the rest of us have not been making a serious effort to get them to upgrade. We now have well over 350,000 Novices and Techs, over 90% of whom have shown no sign of making any effort to upgrade.

This means a couple of bad news things for the AGE group (Advanced-General-Extra). First, it means that one of these days the FCC may possibly notice that the Tech license has totally failed in its whole excuse for being. And this could easily trigger some rethinking of the amateur service, which is right down there at the bottom of the things we want the FCC to think about. Second, it means that when you normalize those "growth" curves by taking into consideration the almost 50% dropout of licensees when that 10-year renewal time finally arrives (through Silent Key-ism, boredom, other priorities such as the XYL and harmonics, job changes, or an interest in newer and more exciting hobbies), we're actually dwindling in numbers. But anyone who's been hamming for a few years recognizes that the bands are noticeably less populated than they used to be. The pileups are more like small heaps. The DX lists are shorter. And the lack of sales of new equipment has the manufacturers and dealers wringing their hands in panic.

"Get 'em involved with your club and then put on demonstrations of HF packet, slow-scan, RTTY and all the other good stuff we have to keep 'em busy for a few years."

A Call To Action!

Your help is desperately needed to turn this disaster around. Your help is needed to get up on 2m and convince the new permanent residents that there really are some fun things to do on the HF bands. Keep on talking about what you've been doing on the other bands. The interesting nets on 75 (yes, there are some), the DX on 20 and 40. The openings on 15 as the sunspots blossom.

Let's get more of our repeaters to work crossband to the low bands. I used to have WR1AAB, my repeater on Pack Monadnock, so it would crossband to either 6m and 10m. It's no big deal to do, but it sure does give the 2m hermits a little peak into the outside world. Maybe you can organize groups in your club to beat the 2m bushes and get the Techs to come to meetings where you can help them upgrade with tech sessions and maybe even some 13-per code. If you teach 'em 13-per my way, they'll learn it in a fraction of the usual time and avoid entirely that incredibly frustrating 10 wpm plateau.

Get 'em involved with your club and then put on demonstrations of HF packet, slow-scan, RTTY and all the other good stuff we have to keep 'em busy for a few years. If you're properly geared up, contests can be a blast. I had a ball in the Sweepstakes for many years. Ditto DX contests, VHF contests, and so on. Get 'em interested in certificates. Get your DXers to show off their cards. If you have any DXpeditioners around, have them put on a slide or video show of their recent DXpeditions.

But the main thing is to invest some time on 2m and help pry the barnacles loose from the repeaters and get them to upgrade. Treating 'em like CBers will alienate them and they'll soon be everything you dread. No, you've got to get up there and mix in and do your selling job.

If you know anything about selling, you understand that to sell you have to point out the benefits to your customer of the product you're selling. Thus, instead of putting Techs down for being lazy, keep at 'em on the fun they're missing. If you can't set up some crossband contacts to give them a taste, at least play some tapes of DX you've worked. Brow-beating won't work. Shame won't work. Being nasty sure won't work. Those are proven ways not to sell. Pictures of $100,000 shacks on the cover of ham rags isn't much of a turn-on either. Look, if the Techs on 2m act like CBers, it's you who's made it happen, either by not talking them down to the HF bands, or by being unfriendly on 2m.

Sure, there are some real jerks on CB. But if I were just getting interested in radio communications, that's where I'd head to start. And I've had endless wonderful contacts on CB. I find that often I have a better chance at talking with people on CB than I do on 2m when I visit a city. On 2m I'm either frozen out by a closed repeater or ignored when I call in. Hello, is anyone there? Not often.

You personally can do more to help keep amateur radio alive if you join the ARRA and proselytize the HFs to our increasingly alienated Techs. Maybe we should organize some merit badges for successful Generalizations of Techs. I'll be watching the club newsletters for word of 2m rescue activities. Oh yes, one more thing, please call your club secretary and get him or her to put me on their mailing list. I want to keep track of what your club is doing. Or not doing. Wayne Green W2NSD/1 - 73 Magazine - 70 N202 - Peterborough NH 03458-1107. Please don't disappoint me.

And if I see a mention of the ARRA in the club newsletter I'll send one of my free prize subscription offers to the club. Yes, that's a bribe. 73

Communications Simplified, Part 2

Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

After our introduction to sound and audio in the first part, we now continue with pictures and video.

Video

You can send pictures through communications in various ways, but the most common means today are fax machines and television. So let's talk about those.

Fax Machines

Twenty years ago, fax machines were very rare, though not entirely unknown. Currently, almost every office has at least one fax machine.

Today's fax machine can send letters, pictures, cartoons, photos, and almost anything that you can feed through its slot. Shown in Fig. 1, the typical machine consists of five parts: (1) a scanner that can scan a printed page and convert it into an electrical signal; (2) a printer that can take such an electrical signal and print it on paper; (3) a telephone and dial by which to call other machines;(4) a modem that couples the digital circuitry to the telephone line; and (5) a microprocessor that ties it all together and makes it work.

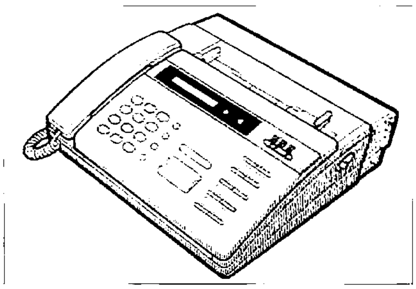

Fig. 1. A typical fax machine.

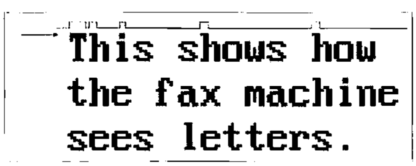

Fig. 2. Enlarged view of some text being sent.

Since the fax machine contains both a scanner and a printer, it can usually be used as a copier; that is, it can scan one piece of paper, and at the same time create a copy of it in the printer. But that's a secondary function. Its main purpose is to transmit that page through the phone to another machine.

To begin the process, you insert the page you want to send into a slot on the fax machine (the slot is on top of the machine illustrated), pick up the handset, dial the number of the machine you want to reach, and wait for the call to go through.

When the called machine answers, it sends back some tones whose purpose is to let your machine know that the connection has been made. When you hear these, you generally press a START button, hang up the handset, and wait for the call to finish.

Let's skip ahead to this point, and look at how your fax machine scans the page you want to send. Fig. 2 shows an enlarged view of some typewritten text that we want to send.

When you push the START button, a photosensitive scanner head starts to sweep across your page, from left to right, starting at the upper left corner. The small arrow at the top left of Fig. 2 shows where the scanner starts and the direction in which it moves. It never sees your entire text; rather only the narrow area of white and black over which it passes. Also, the scanner sees only the tops of the letters "th" and the top of the dot over the "i" (as well as the tops of the two "h"s farther on the right), since all the other letters are shorter. As it scans from left to right, it sees the dark areas shown in Fig. 3.

This is an important concept to understand: The fax machine doesn't actually try to read the letters themselves. It only looks at the patterns of white and black. In other words, your page could contain English, Chinese, or Russian letters, drawings, or chicken scratchings. Only the patterns of light and dark are sent.

As the scanner goes across the page, it outputs a waveform like that shown at the top of Fig. 2. This is a digital signal that shows a low value of voltage when the scanner is passing over white paper, and a higher voltage when it passes over black ink. Although more expensive fax machines can handle grays, the typical cheap fax machine doesn't sense differences in grays. If a gray is light, it's treated as if it is white; and if it's dark, then it's assumed to be black.

As the scanner head is moving right, its output is sent to the microprocessor as a digital signal. When the head reaches the right margin, the microprocessor goes to work; meanwhile, the head returns back to the left and the paper moves up about 0.005 inch. Eventually (after the microprocessor has finished processing this signal), the head will start another sweep across the page, but this time about 0.005 inch lower down on the paper. It will then scan another strip of text, and so on, until it eventually reaches the bottom of the page. In this way, the 11-inch height of the paper is divided into about 2200 strips, each about 1/200 of an inch high (that's equal to 0.005 inch), and each strip is scanned for light and dark areas across the width of the paper.

Fig. 3. What the fax scanner sees.

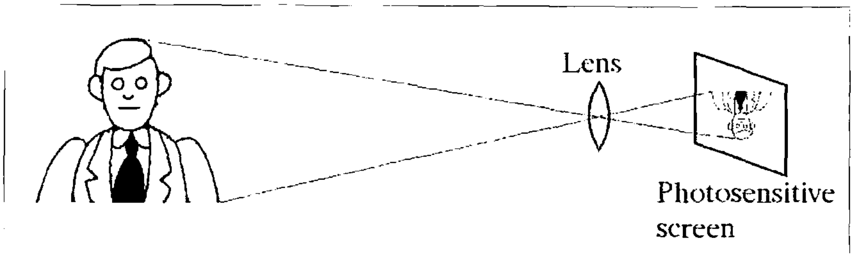

Fig. 4. A simplified black-and-white TV camera.

But let's return to the microprocessor, which gets the signal shown at the top of Fig. 2. This signal has only two voltage levels (assuming we're dealing with an inexpensive black-and-white fax machine.) A digital signal like this can't be directly sent through the telephone line; besides, it would be inefficient to do so. And so the microprocessor analyzes the signal and sends a *description* of the signal, rather than the signal itself.

The microprocessor measures distance on the paper in *pixels* rather than inches; each pixel being 0.005 inch. (A typical fax machine actually has a fine mode and a coarse mode, depending on the sharpness and detail you want. I am using the numbers for fine mode in this description.) The word pixel is an abbreviation for *picture element*, and it is the smallest spot that the fax machine can see or print. If you look at the printout in Fig. 2, you can see that the letters look as though they are made out of square blocks; these are the pixels. The 8.5-inch width of the paper is therefore about 1700 pixels wide.

As the microprocessor receives the signal from the scanner head, it counts off the number of pixels of white and black, and generates a description of the signal in terms of pixels. For example, if it sees an entirely blank sheet of paper, it simply sends a message to the other machine that there are 1700 white pixels. On the other hand, if there is a lot of printing on that line, the description might read:

- 10 white pixels
- 3 black pixels
- 17 white pixels
- 7 black pixels
- 12 white pixels
- 9 black pixels, etc.

You can see that the description of a blank line is a lot shorter than the description of a line with a lot of print. Hence, how long it takes to send a page depends on how much writing is on it. A blank page might feed through in 10 or 15 seconds, an average letter might take 30 seconds, or a page of newsprint might take almost 2 minutes. You can notice the difference as you watch the machine send or receive a page. Blank or nearly blank pages feed through at a speedy clip; complex pages feed through in tiny spurts.

The advantage of sending descriptions rather than the actual waveform is that *for an average page* this takes less time than would sending the actual waveform.

At this point, it doesn't pay to delve much deeper into the fax machine, since my primary purpose in discussing fax machines is to lead into a discussion of TV; let's just say that the description coming out of the microprocessor is itself a digital message. Since the telephone line is not able to carry digital data directly, a *modem* converts the digital data into tones that are then transmitted through the line. The word modem stands for *mo*dulator/*dem*odulator, the device that converts (modulates) data to tones on one end, and then changes (demodulates) the tones back to digital data at the other end.

Before moving on to TV, let's just summarize: The fax machine divides the printed page into horizontal strips about 0.005 inch high (and therefore about 2200 strips per 11-inch page), and scans each strip from left to right. The black/white information from each strip is sent from the sending machine to the receiving machine, but as a description rather than as the data itself. It takes anywhere from 10 seconds to perhaps 2 minutes to send a page, depending on its complexity, which means that the time to send the information for one strip takes anywhere from 10/2200 second (about 0.005 second) for a near-blank page, up to about 120/2200 second (about 0.06 second) for a fairly complicated page. In terms of what we learned about bandwidth in Part 1, it takes a fairly long time to send the picture an therefore not much bandwidth is needed.

Television

Let's summarize normal TV in terms similar to what we just did for fax machines. The TV camera divides a picture into 525 nearly-horizontal strips (the height of the strip depends on the sizeof your TV screen), and scans each from left to right. The information, which includes not just black and white but also grays and colors, is sent as the actual waveform, not as a description. Regardless of how complex, light, or dark the picture is, it takes the same 1/30 of a second to send that waveform. Furthermore, in order to provide the feeling of motion, the TV camera sends 30 complete pictures per second. As you can guess, the bandwidth for a TV signal must be much higher than that of the fax signal.

Let's look first at what the TV camera does. Fig. 4 shows how a lens focuses an image of a person onto a photosensitive plate inside the camera. In studio cameras, that photosensitive plate is inside a vacuum tube called an *iconoscope*. Older home cameras used *vidicons*, whereas the latest home cameras use charge-coupled devices (CCDs). Either way, the photosensitive screen gets an upside-down image of whatever the camera is pointed at. This image is then split into strips and scanned.

In an iconoscope or vidicon, that scanning is done by a thin electron beam, which is aimed at the screen; in the CCD, the screen is itself divided into tiny spots, each of which can measure the amount of light hitting it, and electronic circuitry then interrogates each spot to see how much light it got. Since the studio cameras use iconoscopes, I will talk about the beam as doing the scanning.

As in the fax machine, scanning is done from left to right, and top to bottom of the picture. But since the picture in the TV camera is upside down, in the camera it starts at the bottom right, and goes from right to left, and bottom to top, as shown in Fig. 5.

You'll note that, unlike in the fax machine, the strips in the TV camera are not exactly horizontal. There is a very slight tilt to them, because as the scanning goes

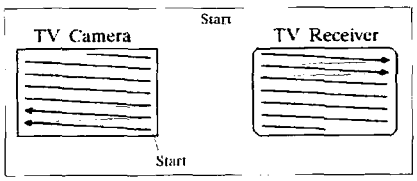

Fig. 5. Scanning in the camera and receiver.

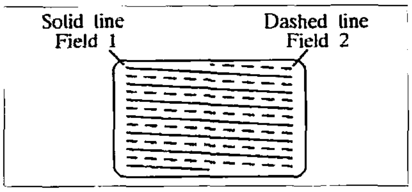

Fig. 6. Two fields make a frame.

from side to side, it is also moving upward, although much more slowly. You can also see a thin line, called a *retrace* line, which shows how the beam jumps from the end of one line to the beginning of the next.

Fig. 5 also shows the beam as it moves in the picture tube in your home TV receiver. Here again, you will note that there is a slight tilt to the lines,. but here the scanning starts at the top left, and so the beam moves slightly down as it moves right. What is impressive about the whole setup is that the beam in the camera is exactly synchronized with the beam in not just your TV set, but also the beam in every single other set that is tuned to the same station. At the exact instant that the beam is at the bottom right corner of the camera screen, it is at the top left corner of possibly millions of TV sets around the country. This must be so to make sure that an item in any particular spot of the picture shows up in the corresponding spot on the screen!

Let's return to Fig. 5. The correct name for what we have been calling strips is actually *scan lines* or *sweep lines*. We mentioned earlier that there are 525 strips in the picture, whereas Fig. 5 shows only 6-1/2 lines. What actually happens is that the 525-line picture (also called a frame, named after a frame of movie film) is divided into two 262-1/2-line fields. The first field of each frame ends on a half-line at the bottom, while the second field of that frame begins with a half-line at the top. This is shown in Fig. 6, though obviously the space is not available to show all the lines.

You will note how neatly the lines of field 2 fit between those of field 1. This process is called *interlacing*, so that a normal TV picture is said to be *interlaced*.

To understand why interlacing is needed, let's consider movie film. In order to show motion on the screen, the movie projector projects a series of slightly different frames on the screen, at the rate of 24 frames per second. But if the projector lit up the screen just 24 times each second, most of us would be badly annoyed by the flicker. So the projector actually puts each frame on the screen twice, for a total of 48 "flashes" per second.

Television has a similar problem. It transmits 30 complete frames per second, but to avoid flicker has to light up the screen more often than that. It is not really practical to flash each frame on the screen twice, because then either the TV transmitter would have to send each frame twice (which would require more bandwidth) or else the TV set would have to store each frame in an internal memory so it could display it a second time (which wasn't practical decades ago when TV was designed.) So television was designed to transmit each frame in two halves—the two fields, with 60 fields per second.

Note that storage of frames was not practical years ago, but the prices of memory circuits have dropped to the point where it now is. Most computer monitors (which work on the same principles as those of a TV set), therefore, do not use interlacing.

So let's put some of the numbers back together:

- There are 30 frames per second. (In a color picture, there are 29.97 frames per second, or 0.1% less.)
- There are 60 fields per second (or 59.94 fields per second in color). This means that the electron beam moves up and down 60 times per second in the picture tube.
- Each frame contains 525 interlaced lines, or 262-1/2 lines per field.
- The 525 lines of a frame repeat 30 times per second, so there is a total of 525 X 30, or 15,750, lines per second. Thus the electron beam moves left-right a total of 15,750 times per second (which drops slightly to 15734.25 with color.).

Remember that the beam motion must be completely synchronized between the camera and all TV receivers watching that channel to make sure that all objects appear in the right place on the screen. Making all of these beams move together requires that the beam motion circuitry in every TV set is synchronized with the camera. Let's look at Fig. 7, which is a very simplified block diagram of a typical black-and-white TV set.

The signal coming in from the antenna goes through a box labeled "Tuner, etc." There is actually a lot of circuitry in this box; however, because we're not nearly ready to discuss it, let's just say that this is where the signal is amplified, and the particular channel is selected. The signal then goes into the video detector, whose output is a signal called *composite video*. This signal is in turn sent to the sync separator, which separates the composite signal into three parts: video, horizontal sync, and vertical sync.

The video signal contains the actual picture information, including whether a particular pixel should be light or dark; it also tells what color that pixel should be, except that we are limiting ourselves to a black-and-white TV for now. This signal is amplified by a videoamplifier and sent to the picture tube.

Meanwhile,. a beam of electrons travels from the electron gun to a layer of phosphor material on the screen. Whenever the electron beam hits the screen, the phosphor material lights up to produce a visible spot. You can vary the brightness of that spot by changing the strength of the beam; that in turn is controlled by the video signal from the video amplifier.

The motion of the electron beam (or beams in color) is controlled by the horizontal and vertical *deflection circuits*, which consist of two oscillators, two amplifiers, and the *yoke*.

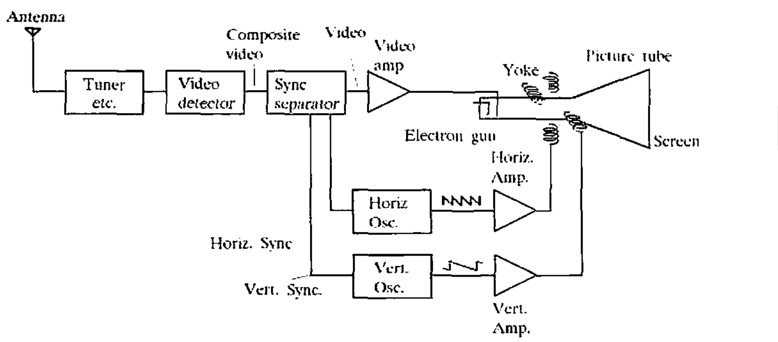

Fig. 7. Black-and-white TV block diagram.

The horizontal oscillator produces a sawtooth wave at a frequencyof 15,750 Hz. This signal is amplified by the horizontal amplifier, and sent to a pair of coils in the yoke. The yoke looks like a doughnut-shaped ring that is slipped over the neck of the picture tube. It contains four coils that produce a magnetic field as current flows through them. Two coils, positioned above and below the neck, move the beam left and right, while the other two move it up and down.

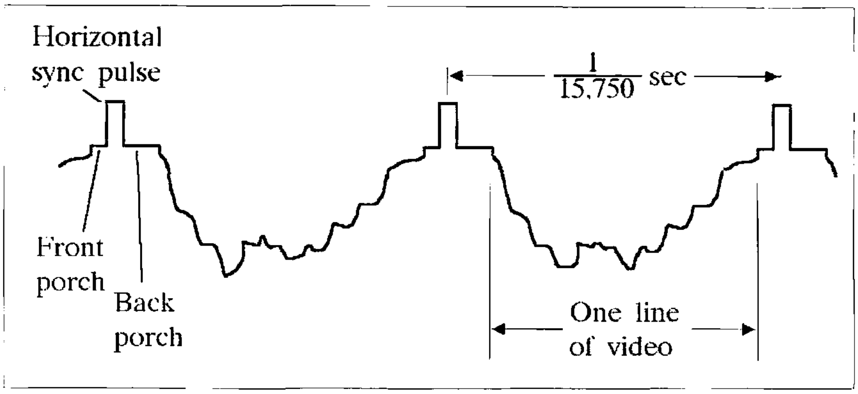

Fig. 8. Composite video signal.

DETOUR

Detour 1

We've been avoiding discussing color for awhile, but since we have to cover it eventually, here goes.

In a color set, there are three video amplifiers and three electron beams in the tube, one for each of the three colors (red, green, and blue.) There are also three color phosphors on the screen, with a "shadow mask" behind the screen that masks the screen so that the red beam can reach only the red phosphor, and so on.

If you look at a color set's screen with a magnifying glass, you can see the tiny color dots (or sometimes stripes) that make up the picture. But if you lean back, the tiny color dots blend together into other colors. For example, when a red dot, a green dot, and a blue dot are all lit up next to each other, from a distance their colors add up to produce a white dot. A red dot and a green dot together, without blue, produce yellow. The various colors on the screen are thus put together out of various combinations of tiny red, green, and blue dots.

Normally, all three electron beams move across the screen together, but their intensity varies depending on what the color is supposed to be at that point.

END OF DETOUR

The sawtooth horizontal sweep signal is sent to the two horizontal deflection coils in the yoke. The sawtooth voltage sweeps the beam from left to right, and then suddenly swings it back to the left (the retrace) in preparation for the next sweep line. Since the beam is normally turned off during that retrace sweep, it can't be seen during that return trip.

Meanwhile, the vertical oscillator produces another sawtooth wave, but this one at 60 Hz. It too is amplified, and then sent to the vertical deflection coils in the yoke. It sweeps the beam slowly down (in about 1/60 of a second), and then rapidly returns it to the top. Again, the beam is turned off during this retrace, but if you turn up the brightness on your set, you may be able to see the beam as it returns to the top. (Actually, it doesn't return to the top fast enough, so you can see it swing back and forth a few times as it returns to the top.

The two oscillators run even if you don't tune in to a working channel. This makes sure that the beam continues sweeping across the screen, rather than settling in the middle of the screen and burning the phosphor at that spot because of too many electrons. But they may not run at exactly the right frequencies, since the components in the oscillators are not precise enough to maintain the right frequencies themselves.

The job of maintaining the exact right frequencies and phases is handled by the horizontal and vertical synchronization (sync) signals, which come from the sync separator. These sync signals originate at the TV studio (typically, a single sync generator in the studio would feed all the cameras to make sure they all sweep at the same time: this is required to allow smooth switching from one camera to another), and are transmitted as part of the TV signal. The sync separator strips them from the composite video signal and sends them to the appropriate oscillator.

Let's return now to the composite video signal, the signal that comes out of the video detector in Fig. 7 to the sync separator.

If you look at the composite video signal with an oscilloscope, you see a signal that looks something like Fig. 8.

Fig. 8 shows three horizontal sync pulses, each separated by 1/17,500 second, the time for one horizontal line. Each of the pulses sits on top of a *pedestal*, which consists of a *front porch* and a *back porch*. The jagged line between any two horizontal sync pulses represents the video signal for one sweep line. As this figure shows, two consecutive sweep lines are generally somewhat similar to each other, though not identical, because they are essentially almost-adjacent strips of the same picture. (I say "almost adjacent," because they are separated by one strip from the interlaced second field.)

The voltage of the video information represents the brightness (also called the luminance) of the picture. In Fig. 8, black is up, near the sync pulses, while white is down, and there are various shades of gray between. This polarity makes the most sense when we talk about a pedestal; keep in mind, though, that most transistor amplifiers invert their signal; thus, depending on where you connect the oscilloscope, the signal may be either as shown in Fig. 8, or upside down (with the sync pulses pointed down, and white being up.) For example, the standard output of a VCR's or camcorder's VIDEO OUT jack is an upside-down signal, with the tips of the sync pulses being down at 0 volts, and the white peaks of the video signal at approximately +1 volt.

A vertical sync pulse occurs once every every 262-1/2 horizontal sync pulses.The shape of this sync pulse depends on the circuit that generates it. In commercial TV, it looks like a half-dozen horizontal sync pulses strung together, with some extra short pulses before and after them; this is often called a *serrated* sync pulse (like the serrations in a steak knife.) In computer monitors (which are usually not interlaced and in which timing is not as crucial), the

vertical sync pulse is often just a single, but very long, pulse.

DETOUR

Detour 2

In the absence of the sync signals—for instance, when you're not tuned to a working channel—the vertical and horizontal oscillators "free-run," meaning that they oscillate without being synchronized to a station. If the free-running frequency is not close enough to the frequencies required by the station, however, the sync pulses may not be able to synchronize them. Hence, most TV sets have a pair of controls, called VERTICAL HOLD and HORIZONTAL HOLD, which bring the free-running frequency into range. You may have noticed what happens when you misadjust these controls.

When you turn the VERTICAL HOLD control off its normal setting, the vertical oscillator's normal frequency varies out of range of synchronization, and the oscillator suddenly oscillates at the wrong frequency. When this happens, the vertical position of the picture will be wrong, and it may roll up or down, depending on which way the control is set.

When you turn the HORIZONTAL HOLD control away from its normal setting, the horizontal oscillator changes to a different frequency, and parts of the picture move left or right. This normally slides the picture sideways and then suddenly tears the picture into diagonal bars.

In addition to VERTICAL SIZE and HORIZONTAL SIZE controls (which vary the gain of the vertical and horizontal amplifiers to make the picture larger or smaller), many TV sets also have a VERTICAL LINEARITY control. This control changes the shape of the sawtooth vertical sweep control, and results in the top of the picture stretching or shrinking a bit. This control is normally set to make people's heads appear the right size.

END OF DETOUR

The pedestal looks somewhat different in a color signal, because the back porch contains nine cycles of a 3.579545-MHz signal called the *color burst*. The color information is carried on a 3.579545-MHz "subcarrier" (we will define that word later) and the color burst is used to synchronize a color oscillator in the TV set. (If you've seen cheap 3.579545-MHz crystals in the Radio Shack catalog, now you know where that crystal is used.)

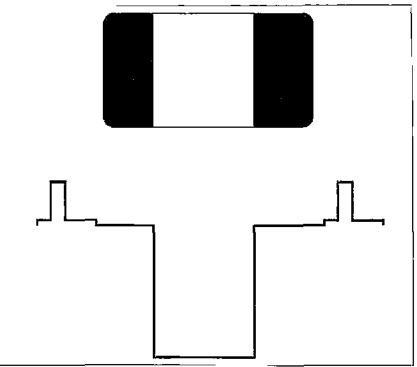

Fig. 9. A TV picture with one white bar.

Bandwidth

Let's return to the question of bandwidth of a TV signal. Suppose we aim a TV camera at a black sheet of paper containing a thick, vertical white bar, and look at the resulting composite video signal; we will see something like Fig. 9.

The top of Fig. 9 shows the screen, while the bottom shows one line of the composite video signal. Since the picture is identical from top to bottom, all the scan lines will look the same.

What we now want to ask is this: What is the spectrum of the composite video signal?

With some fancy mathematical analysis, we could come up with an exact answer. But we needn't go that far if we're willing to accept an approximate answer instead of the exact numbers. Looking at the video signal, we see a signal that, except for the horizontal sync pulse, would look like some sort of a square wave. Its frequency is 15,750 Hz, the same as the frequency of the sync pulses. Since the sync pulse is relatively small compared with the rest of the wave, ignoring it will produce an error in our answer, but not a tremendously large one.

But we already know what makes up a square wave: a fundamental plus odd harmonics. Hence, this signal consists of a 15,750-Hz fundamental, plus harmonics at multiples of 15,750 Hz (but, since the signal is not exactly a square wave, there will also be even harmonics). There will (at least theoretically) be an infinite number of harmonics; however, after the first 100 or so harmonics, their amplitudes will be so small compared with everything else that we might as well forget about them.

Let's now increase the number of bars from one to three, as in Fig. 10.

As before, we can again approximate this signal with a square wave (and even more accurately, because the sync pulses are now even smaller than all the rest of the signal), but this time the frequency is three times higher than before. A square wave with a frequency of 3 x 15,750 Hz, or 47,250 Hz, now consists of a fundamental frequency of 47,250 Hz, and odd harmonics starting at 3 x 47,250 Hz.

In the same way, we could extend our process to as many bars as we want. For example, if there were 300 vertical bars on the screen, then the fundamental frequency of the square wave would be 300 x 15,750 Hz or 4.725 MHz, and the harmonics would start at approximately 14 MHz.

There is only one problem with this idea. If you look at Fig. 2, you see that the received TV signal has to go through the box labeled "Tuner etc." And this part of the TV set generally has a maximum bandwidth of about 4 MHz (depending on the set, with color sets being somewhat worse than black-and-white sets.) In other words, our TV picture with 300 vertical bars will not get through that part of the set because even the fundamental frequency, the lowest frequency in the video signal, lies above 4 MHz!

Even a picture with just 100 bars would have some difficulty. Its fundamental frequency of 1.575 MHz would make it, but even the lowest harmonic, at 4.725 MHz, would not. In other words, the square wave video signal would be reduced to a sine wave. As a result, the signal would gradually change from white to black, or from black to white; on the screen, the edges of the bars would appear blurred.

The bandpass of the "Tuner, etc." part of the TV set puts, therefore, a basic limit on the number of vertical bars we

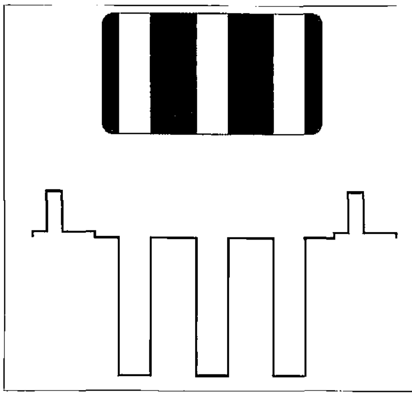

Fig. 10. A TV picture with three white bars.

can display, sharply or not. This limit varies with the set, but is about 250 lines. We call this the horizontal *resolution* of the TV picture.

It happens that the vertical resolution of a TV set is also about 250 lines. Of the 525 sweep lines on the screen, a bit under 500 actually appear on the screen (the others are either above or below the borderof the screen, or else occur while the beam is returning from the bottom back to the top). If these 500 or so lines alternated between one white, the next black, and so on, then the maximum we could get would be about 250 white lines separated by 250 black lines.

It *is* possible to get somewhat better than 250 lines of horizontal resolution on a TV screen, but only by bypassing the "Tuner, etc." portion of the TV set. Many TV sets permit that by having a composite video input jack, or even better, separate connectors for video and sync signals. Many camcorders, VCRs, and laser disks offer better than 4 MHz bandpass, and can therefore provide a sharper image, but only when they are connected directly to these special video input jacks.

Bandwidth thus affects not just the sharpness or resolution of theTV picture, but also the speed at which TV pictures can be sent. The number of lines could be increased either by increasing the bandwidth or by slowing down the transmission so that the entire horizontal line would take longer. For example, the fax machine achieves much greater horizontal resolution at a lower bandwidth by taking more than 1000 times as long to send one line of video.

Or consider TV pictures sent back from a spaceship to Jupiter. Since a wide-bandwidth signal picks up much more noise, space TV signals are sent at a very low bandwidth to minimize this noise. As a result, they must be sent very slowly to maintain any reasonably good resolution. It often takes several minutes to get one picture.

Color TV

When color TV first started, there were very few color receivers, and very few stations transmitting color. So color TV was originally designed to be completely compatible to make sure that customers with black-and-white sets could receive the color stations, and vice versa.

In color TV, everything happens exactly 0.1% slower; there are 29.97 frames per second instead of 30, and the horizontal frequency is 15,734.25 Hz instead of 15,750 Hz. So the composite video signal consists of 15,734.25 Hz and its harmonics.

Let's take a look at two specific harmonics: the 227th harmonic (at 227 x 15,734.25, or 3,571,674.75 Hz) and the 228th (at 228 x 15,734.25, or 3,587,409 Hz). Neatly sandwiched between those, at 3.579,545 MHz, safely out of the way so it won't interfere with either harmonic, is an added signal called the *color subcarrier*. This is a weak signal, carried as part of the color composite videosignal, whose phase at any instant tells the color TV set what color to make the screen at that instant. (A modern black-and-white TV ignores this signal, though early sets used to display a tiny herringbone pattern on the screen when watching a color signal.)

We've already mentioned the color burst signal, a short burst of 3.579545 MHz that sits on the back porch, just after the horizontal sync signal. The color set has an internal 3.579545 MHz oscillator; the color burst synchronizes this oscillator so it is in phase with a master color oscillator in the TV studio. To decide on the exact color to put on the screen, the set compares the phase of this local oscillator with the color subcarrier.

Digital TV

The method we've described up until now is called the NTSC method, named after the National Television System Committee, which defined the method back in the 1950s. It is purely analog; that is, no digital computer circuitry is involved. Keep in mind that computers were in their infancy, and very, very expensive at that.

In 1990, however, while the FCC was considering establishing a new TV service called HDTV, or High Definition TV, a proposal was made for an entirely digital system. Several other companies jumped on the bandwagon, and the current HDTV system design comes from a group called the Grand Alliance: AT&T, General Instrument, MIT, Philips, Sarnoff (the old RCA Laboratories), Thomson, and Zenith.

The Grand Alliance team was formed after several different groups proposed several different (and incompatible) schemes. Rather than give anything up when they merged, they incorporated everything into the final HDTV proposal. So the HDTV system includes six picture formats:

frames/sec	scan lines	resolution	interlaced
60	720	640	no
24	720	640	no
30	720	640	no
30	1080	960	yes
24	1080	960	no
60	1080	960	no

Table 1.

The rationale for including all six formats is that different formats could be used for different types of programs. For example, movies (which run at 24 frames per second) would not have to be converted to 30 frames per second, as happens now.

The HDTV system also includes five channels of sound for stereo and surround sound, and even provisions for extra data channels for sending computer data.

If all of this were done with analog methods, the bandwidth would be much larger than current NTSC television, which would mean a reduction in the number of TV stations allowed. But sending the pictures digitally allows digital compression methods to be used. For example, since two consecutive picture frames tend to be very similar, TV stations could transmit just the differences between them. The digital circuitry in the receiver would then insert the changes into the preceding frame, stored in digital memory, to make the new frame.

As a result, the complete HDTV picture would fit into the same channel format as current TV. Although you would need a new (and much more expensive) TV set to receive HDTV, there would be a period of transition when both NTSC and HDTV stations would transmit at the same time. The hope is to be able to sandwich HDTV signals into the unused channels between current NTSC stations, without causing interference in either direction.

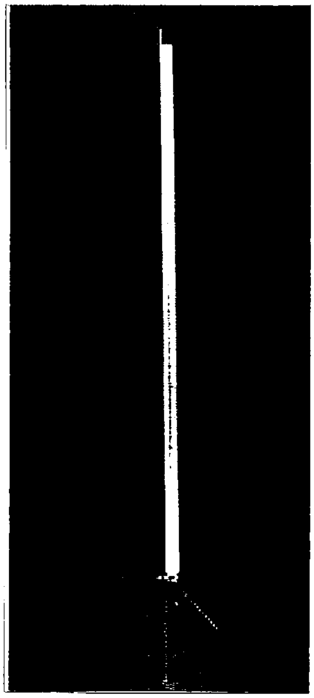
NEW PRODUCTS

Low Profile 2m-70cm Antenna

The Genesys G-1, from Genesys Products Group, provides 3 dB gain on 146 MHz and 6 dB on 446 MHz. It's 42" high, and has three ground-plane radials and an SO-239 UHF connector. It has a white fiberglass top and an aircraft aluminum base. It comes with U-brackets that will fit up to 2.5" masts. List price: $99.95. For more information, circle Reader Service No. 202.



The Genesys G-1.

A New Battery!

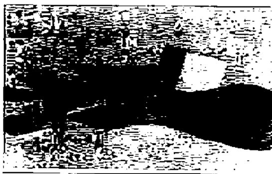
Bolder Technologies has come up with a new lead-acid battery design that looks like a real winner for applications requiring a lot of current and a short recharge time. They've made their cells much like a capacitor, using thin lead foil and an electrolyte instead of a dialectric material between the windings. Each cell is about 1" x 3" and provides about 2 volts. These are going to be very useful for power tools, uninterruptable power systems (UPS), portable equipment, electric scooters, and even cars. A battery weighing less than two pounds can start a car 20 times on a single charge! Being lead-acid, it doesn't have the memory problems of NiCd batteries.

One other factor is that there is a well established recycling industry for lead-acid batteries, and none for the far more toxic cadmium or lithium.For more information, circle Reader Service No. 204.

Manufacturers please send your products to be reviewed to Richard. Call 603-924-0058 for details.

Dalco Data Protector

Don't you hate it when you are online with your computer and someone picks up another extension and starts dialing, destroying your connection? Dalco to the rescue with their Data Protector™, a $17 gadget that disconnects other extensions when you are using the line. It'll stop any eavesdropping too, if that's a problem. Discounts on the purchase of three or more units. For more information, circle Reader Service No. 203.



Dalco Data Protector

Hidden Antenna Kit

Just the thing for cliff dwellers and covenant-restricted hams. Check out the TapeTenna from Hamco, with 108 feet of half-inch wide copper foil tape, connectors, and an instruction book. The tape will stick to just about anything, indoors or out. You can even paint over it to make it more invisible. It's $34 ppd. That's cheaper than moving to a more ham friendly QTH. For more information, circle Reader Service No. 201.

ABOVE & BEYOND

Continued from page 64

You would not want to pick up a laser head that was miswired. External power supplies providing the several thousands of volts needed for the operation of a laser head provide a ground to the negative portion of the power supply. I have found this wire to be somewhat small gauge and prefer to operate my systems with a much larger system ground that ties common with the power supply and laser head. A sturdy copper braid like coax shield has been successful. The braided shield provides a great deal of flexibility and a sturdy conductor. Whatever you use make sure your equipment is grounded and that the protective case ground is just that: *ground*. A new laser can be obtained but there is only "*one of you.*" Safety First!

Laser Power Supplies

There are several different types of laser power supplies available. They range from units that can be operated from 110 AC to 12 volts DC input. For our applications the 12-volt DC supplies are the most desirable. These supplies make portable operation possible without DC-to-AC inverters and long power cords. Though it is possible to build a switching power supply using a single toroidal cup core transformer with a 12-volt primary, I found the winding process quite tedious. Think of it with 30 or so turns at 12 volts. How many turns does it require to obtain something near 1500 volts?

I tried constructing a 12-volt laser power supply using a large cup core transformer scrounged from surplus PC boards. The cup core was an inch and a half in diameter and one inch high. I wound the primary with 60 turns, center tapped, which filled one layer of the cup core. I insulated the cup core from the primary with Teflon™ tape used for plumbing applications. I overwrapped the primary winding to further insulate the primary and secondary with the same Teflon™ tape using several layers of tape. I then started to wind the secondary with #40-gauge insulated wire. I have to admit I lost count of the turns on the secondary several times as winding some 600 turns proved to be harder than I had thought.

Now the final scenario. After locating high-voltage rectifier diodes (not the 1,000-volt variety but 10,000 volts) and some capacitors rated at 3,000 volts, you can expect a good dent in your pocketbook. Why these high-voltage components? Well, this is part of the extra circuitry that needs to be applied to a laser power supply to provide something over 1,000 volts at a few mA. What is needed is a circuit added to the high-voltage path to provide a 10,000 or so peak starting voltage when the laser supply is first turned on, to ionize the gas in the laser head. After the laser is ionized the lower voltage will sustain the ignition and operation of the laser.

The ignition circuit is nothing more than a series voltage multiplier that boosts the 1 kV DC to about 10 kV for a very short interval only, when the laser is off and just before it ignites. When the laser ignites, this circuit self-disconnects electrically, allowing the low-voltage power supply to flow through this network. The circuit does not function as a multiplier, but rather like a series pass element. The multiplier will only function at microamp current

Communications

Continued from page 71

One interesting aspect of HDTV is that, although it is very different from NTSC, it has been purposely designed to be compatible with computer applications. The idea is that the same HDTV sets could also be computer monitors. Since the digital transmission method used for HDTV can accommodate digital data as well, there is an underlying hope that television and computers will merge into the ultimate tool for the "information superhighway" of the future.

Summary

Although this part has just been a limited introduction to television, it has covered several important concepts. Aside from an idea of how TV works in general, we have once again seen the impact of bandwidth on the transmission of information, and also once again seen the interaction between bandwidth and time. Although we haven't provided any definite proof (that would require some advanced math concepts), we still begin to see that bandwidth is a necessary part of communications. If a signal has no bandwidth, then it cannot transmit any information at all.

Hamsats

Continued from page 54

of 10 in the last 30 years, and the sophistication of the payloads has paralleled that of electronics advances over the same period. The equipment in the control room reflected the high level of technology required for flight control and monitoring.

Dwight showed the group a telemetry support package that straps onto a customer payload. The telemetry unit weighed a few hundred pounds and included the equivalent of a Pentium PC ruggedized for the rigors of high-altitude flight.

Getting a huge balloon and massive payload into the sky is a complex job. Winds must be below a few miles per hour and several vehicles are needed at the launch site. A minimal launch requires a helium truck, a spooler vehicle to deploy the balloon and lines, and "Tiny Tim." Tiny Tim, at the NSBF, is an electrically powered vehicle that holds the payload, and can be maneuvered under the balloon during launch so that the balloon, parachute, lines, and the multi-thousand-pound scientific package take off straight up. Just standing next to Tiny Tim gives a sense of how large the payloads can be. The wheels on the vehicle are nearly seven feet tall.

There were no launches at the time of the tour, but the public is welcome to watch from nearby roads when one does occur. Although most launches are scheduled for early morning hours or nighttime, variables such as weather conditions make it difficult to predict actual launch times. A typical launch may take two to three attempts due to conditions at the site.

One-hour tours are available by appointment and launch schedules can also be requested. If you are passing through east Texas, stop in Palestine. A visit to the NSBF is well worth the effort. The number to call for tours or information is (903) 729-0271. For other general information about Palestine, contact the Palestine Chamber of Commerce at (903) 729-6066.

Photo E. The payload launch vehicle is electric and big, *with Mike WA5TWT (Ken Axelson photo).*

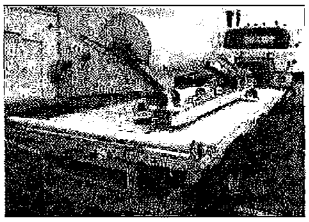

Photo F: The balloon spooling unit is required for proper balloon and line deployment during launch (Ken Axelson photo).

Never Say Die

Continued from page 4

and blinders of the establishment. Stock in the Big Bang has been dropping fast on the scientific stock market.

Okay, we have little balls of energy spinning, with the energy going around the outside of the ball and up into the center vortex and quickly coming out the bottom again. As we know from whirlpools, tornadoes, and plasmas, vortices suck. This force holds the ball of energy together. It also tends to attract any nearby energy balls, thus providing what we perceive as gravity.

"It's matter being made up of spinning energy fields which cause inertia."

In my editorials in *Cold Fusion* I've suggested a new model for the atom. I give full credit for the direction my thinking has gone to *Cold Fusion* scientific advisor M. Srinivasan of the Bhabha Atomic Laboratories in Bombay, who put me onto the book *Extra-Sensory Perception of Quarks* by Stephen Phillips. And that book drew, in a large part, on the work of Besant and Leadbeater, as reported in their book, *Occult Chemistry*, which was published in 1908. Almost a hundred years ago! Using meditation, they either were able to visualize atoms and their constituents or else they were two of the luckiest guessers in history.

The next resource for me was Eric Lerner's *The Big Bang Never Happened*. Putting the data from these two sources together helped explain for me how the coulomb barrier could be breached for the cold fusion reaction. Then, as I got to thinking more about it, this also explained inertia. I'd recently read Peter Graneau's *Newton Vs. Einstein*, which confirmed that not even Einstein was able to figure out why we have inertia.

Now, if you figure that electrons and protons are made up of smaller energy bundles which are shaped like fat spinning balls with a tight vortex in the middle, you'll get the idea. These are balls of energy, whatever that is. Now, if you spin a gyroscope you have to exert an outside force to move it, and then it will keep on moving until another force changes its motion. Just like inertia. Thus, it's "matter" being made up of spinning energy fields which causes inertia. If you have a box full of gyroscopes, all spinning on different axes, you'll cancel precession.

Physicists messing with atoms and quarks agree there's spin involved with everything. And antimatter just has a reverse spin. So when you mix the two you have all that energy suddenly released. Whamo!

Doesn't that all make sense? Now, what is this energy stuff that's spinning around?

Well, you can see why I'm having so much fun with all this. Sure, I'm probably wrong. History says so, for every atomic theory in the past has eventually been proven wrong as our ability to extend our senses with instruments has developed. And ditto our cosmological theories, no matter how fervently held. Ask Galileo.

I tried out my theories in *Cold Fusion* editorials, since they're read by many physicists. I've had some enthusiastic responses, and no negatives. That really surprised me. Well, I'm reading and learning as much as I can. How about you? Are you drinking beer and watching ball games or learning new things? I don't know of anything more fun than grasping new concepts. Well, maybe skiing like a bat out of hell down a mountain, carving those turns. Or working the only station in Iraq and having a chance to more than swap QSL information.

Speaking of Iraq, I hope I'll be able to find time to start putting together some slide shows on my computer so you can see what I saw on my visit to Iraq. I took some fabulous pictures and now I've got a J-Peg program to scrunch 'em onto a disk. The next step will be the development of a way I can send my pictures and stories over 20m. How about working on that for me? And writing it up as you progress?

Magnetic Power

There's what has given me the impression of a lunatic fringe lurking just outside the cold fusion field, probably attracted by visions of yet another source of free energy. Some of them are believers in the magical abilities of certain type of coils to generate an anti-gravity force. Others are firm believers in what they call zero-point energy. This has to do with being able to tap what they believe is an enormous amount of

Continued on page 76

How About a 2W 40m
Continued from page 51

inside the NorCal 40A to mount the keyer/counter and make the great little rig even better.

If the new builder ends up bungling the kit, he can send it back to Wilderness and get it fixed for a flat fee of $50 plus $5 shipping, provided it is repairable. Technical support is available Monday through Friday from 10 a.m. to 5 p.m. Pacific time. The kit currently sells for $129 and is well worth the money.

I made sure I really took my time building this kit. I have learned that it takes a lot less time to build it right the first time than it does to fix it later, and there is a lot less tension produced. The NorCal 40A has a small parts count, which made this kit very easy to build.

The printed circuit board was fantastic. The silk-screening was very clearly marked so there was no doubt in my mind where each part went on the board. It was also a pleasure to solder. The board seemed to just suck up the solder. You should use a sharp-pointed soldering iron of 20 to 45 watts. When you solder remember to keep the tip at an angle and heat the soldering pad on the board and the wire coming through. Allow the solder to flow freely for a second before removing the iron. This will make for much better soldering joints. I found that even though I was really taking my time, the kit went together very quickly.

Sneaky Toroid Trick

The only possible obstacle I can see for the new builder is winding the toroids. Oak Hills has gone to providing these pre-wound. I believe that anyone can easily wind their own toroids and get a real sense of accomplishment doing so. There are easy-to-follow directions provided in the manual. The VFO toroid requires a large number of turns. I cheated. I had my wife wind the VFO coil and she did a beautiful job.

One thing I really appreciated was the quality of the magnet wire provided. I find that it is easy to wind the toroids if you take your time, but that in many cases you can easily mess up when it comes to removing the insulation on the ends that get soldered to the board. If you get too rough they tend to break. The wire provided with this kit for winding the toroids has heat-melt insulation. When you are done winding you take a lighter and melt off the insulation at the ends, then take some sandpaper and make sure they are clean. You might want to check for continuity in the sets of wires with an ohmmeter before you solder them to the boards.

When you finish most kits there are a number of wires you need to hook up to connect various controls and jacks. Since this kit had all board-mounted controls and jacks, when I was done putting all the parts on the board, I was pretty much done building. It didn't take long to mount the printed circuit board to the bottom cabinet.

The Old Smoke Test

No matter how many kits I build, I always get nervous when applying the power. It can be a bit depressing to smell smoke. Make sure you have the polarity of your power source correct. The manual provides a chart for you to check voltages should you find there is a problem. If you smell smoke, turn it off!

The manual clearly tells you to set the trimmer capacitors and variable resistors to

their initial positions. You next hook up a set of headphones that need to have a stereo headphone plug. You hook up an antenna and turn on the rig. I heard a hissing in the headphones; well, at least one part of the rig appeared to be working.

To align the receiver, you simply adjust two of the trim capacitors while listening for a signal. The adjustment is fairly sharp. When you get it right it is obvious because the signal you will hear will be a lot louder at this point. You will next need to adjust the VFO to the correct frequency. I have a frequency counter and used it, but you can do the alignment with a transceiver, preferably one with a digital readout. The rig came up close to frequency and it only took me a minute to adjust the frequency to where I wanted it. If you don't modify the rig you should be able to adjust it for any 40 kHz of the 40 meter band.

The rest of the kit was a breeze to align. You adjust a trim capacitor for the BFO pitch and set the AGC control, if you want to use it. To adjust the transmitter you adjust one variable resistor for power output. Make sure you use a dummy load or at least have an antenna hooked to the rig when keying it. I use a QRP wattmeter to adjust the power. If you don't own one you can simply adjust the control as described in the manual. A couple more simple adjustments and you are done.

Hey! It Really Works!

I hooked up the power, a small amplified speaker (I don't like headphones), the antenna and a key. I tuned around and found signals popping out clearly. The receiver seemed to hear well and was quiet. I tuned around and heard KFØN calling CQ. I gave him a call and he immediately came back to me. Larry was located in Cedar Rapids, IA. I was using less than 2 watts to a ground-mounted vertical antenna. After exchanging signal reports, names, and QTHs, he said "FB, wow! Your 2 watts doing a splendid job up here." We ended up talking for over half an hour. I noticed that the VFO on my rig was stable, so I didn't have to mess with the controls during the QSO. It turned out that Larry was on a Heathkit HW9 running 4 watts. I took this as a sign from above. My favorite QSOs now are QRP-to-QRP. We spend our time talking about QRP and various kits. It is hard to explain in words how much fun that first contact was and how loud my yell was when I first heard him come back to me.

After finishing with Larry, I worked Rich WB2VPH in Brockport, NY. I next worked Steve NØJGU/M near St. Louis, MO, and then many more contacts, one after the other. I was able to hear many stations and work all the ones I heard. I got consistently good reports on how my rig sounded and how well my signal was getting out. Who can ask for more than that?

Increasing the Tuning Range

Modifications that you can add are listed at the end of the manual. The one I did was to replace the 47 pF NPO capacitor in the VFO circuit with a 56 pF NPO. This gave me 60 kHz of coverage from 7.000-7.060, which is all I use of the band. This modification causes the RIT to have a greater range. You can simply change the value of this capacitor while building the kit. Make sure you use an NPO capacitor to maintain the stability of the VFO. There is plenty of room in the cabinet to put in a 10-turn pot which will increase the VFO range up to 150 kHz to get the full CW band coverage.

The bottom line is that this is one great kit. It was a lot of fun to build and it really works. The receiver is both sensitive and selective. My rig has a very stable VFO so that I stay on a given frequency. The 1.8 watts seems to be enough for me to work most everything I hear. The rig is very small and can run for quite a while with a small gel cell. This makes it an excellent backpacking rig. I find one of my greatest enjoyments in ham radio is talking to other hams using battery power on a little transceiver that I built myself. 73

The Details

DC Power Requirements: 10 to 16 VDC: reverse-polarity protection
- Receive: 15 mA
- Transmit: 225 mA at 2.0 watts output

Frequency Coverage: VFO operating frequency: 2.085 MHz nominal
- Covers any 40 to 45 kHz segment of the 40m CW band (7.0-7.15 MHz)
- Drift: 100 Hz total from cold start at 65 degrees F

Transmitter: Output: 0 to 2 W, adjustable
- Final amplifier efficiency: 70-80
- Load tolerance: Brief operation into high SWR
- Transmit offset: 400-800 Hz, adjustable
- Transmit-receive delay: 200 milliseconds

Receiver: Sensitivity: Better than 0.5 uV for 10 dB S+N/N
- Selectivity: 400 Hz @ -6 dB, 1.5 kHz @ -30 dB
- IF: 4.915 MHz, 4-pole Cohn crystal filter
- RIT Range: +/- 2 kHz at center of VFO tuning range
- Audio output impedance: 8 ohm or higher (head phones or speaker)

NEVER SAY DIE

Continued from page 74

energy that exists in the "ether," a.k.a., space. Not being able to grasp the concepts involved, I've been awaiting something more substantial than the emotional writings of the True Believers to convince me, thus irritating the hell out of them. But then I've never been swayed by the emotional attacks from True Believers, whether they be proselytizing or defending a religion, the ARRL, CW, or some imagined potential ecological disaster.

If these so-called "N-machines," which are powered by magnets, are so great, let's see one working, was my approach. A reader from California called to say that he had followed up every reported working N-machine in the world and had yet to find one that would work when he was watching.

Thus, when I recently got a press release about a coming demonstration by Yasunori Takahashi of a working N-machine in Switzerland I faxed the London source of the release, asking for more information. I remembered getting a story several months ago about a Takahashi magnetic motor and its use in a scooter, so this seemed worth looking into. A return fax said the Swiss demo had been canceled. Hmm.

A few days before Thanksgiving Sherry said why don't we zip over to London for the weekend? We'd done this several times in the past, flying over on Wednesday evening and back on Sunday, thus not missing even a day's work. Several airlines have amazingly low cost package tours...if you call around $600 for the round trip, including ground transportation, hotel, and a London show, low cost. That's about what it would cost to stay in a New York hotel for three days, and never mind the meals. So I set up a meeting with the London Takahashi representative for Friday.

"Perpetual motion seems to be here. This is obviously impossible."

We'd gone via TWA in the past, but this time we tried British Air. Never again. Oh, the trip over was all okay, but they got us to the Royal National hotel by around 9 a.m. Thursday and the crummy hotel wouldn't give us a room until after 2 p.m. Not having been able to get much sleep in the cramped plane seats, we were in lousy shape to sight-see London. We wanted to sleep!

We took the underground downtown to see some tourist attractions for which we'd been given free tickets. When we got to the Tower of London, it was closed. Ditto the Banqueting House. We did see a few minutes of the Queen's Horse Guards on parade, and then we

walked a couple of miles back to the hotel, checking on what shows were running as we passed the theaters. None of the shows looked very good so we tossed a mental coin, which came up tails, and traded in our coupons for tickets to "Funny Money." When we got back to the hotel we sat. And sat. At two we got our room and crashed, leaving a call so we wouldn't miss the play.

The play was surprisingly terrible. I've seen far better on some silly British shows on PBS. But it wasn't much worse than the show we caught when we stopped by London on our way to Paris and Monaco for the March cold fusion conference. It was a comedy. I almost laughed a couple of times.

The next morning we went down to the hotel's $18 English breakfast which was included free with the tour. Major bummer. The oatmeal was cold. The poached eggs like rocks. The toast cold. The bangers yuuck. The stewed prunes hadn't been stewed. The OJ had a slight orange flavor.

We've done this London Thanksgiving tour thing many times, and TWA has always put us in top-notch hotels with superb food. Thanks BA for finding this hellhole for us. Everything about the hotel was cheap and shoddy.

After we recovered from the breakfast we took the underground to the suburbs and were met at the station by Takeo Sawai, who drove us to his home. There I was introduced to the Takahashi scooter. It had a small battery, used to get it started. Once running, the electric motor-generator takes over and runs the scooter, as well as recharging the battery. Yep, the motor runs a generator which then completely ignores the laws of physics by generating enough current to run the scooter and recharge the battery. Perpetual motion seems to be here.

This is, obviously, impossible. And the fact that the scooter could carry two heavy men uphill at a very brisk speed meant that some clever magic was being used. I put on a helmet, climbed on, and zoomed away, dodging oncoming traffic, as I sped around the London streets. Hey, this thing sure has a lot of pickup. It seems to have more power than my Yamaha scooter, which is no slouch.

The secret is in the magnets built into the motor. These are no ordinary magnets. I brought a few home to astound people with their power. I let one get within a foot of my underground ticket and it erased the magnetic stripe so the ticket wouldn't work any more.

The Background

Mr. Takahashi has some impressive credentials. He worked for Sony for several years and was involved with the development of their Trinitron, the Betamax, and the Walkman. This is not a hoaxer. Further, in addition to inventing the super-powered magnets used in his motor, he's also invented a capacitor dielectric that is unbelievable. Well, it would be except I have a copy of the patent.

The magnet came from Takahashi's work in developing high density magnetic material for videotapes. It's made of needle-shaped micro-magnets of yttrium, iron, manganese, X, which are glass-bonded. It has a coercive force of about 15 times that of alnico.

In reading the capacitor patents I found that Takahashi has developed capacitors which are 1/20th by 1/10th of an inch and have 250 µF capacity! That works out to about one Farad for an inch-square capacitor! Who needs batteries when we have such small sized capacitance available?

I hope one of these days to be able to get together with Takahashi and a good interpreter, so I can learn more about his dielectric, his magnets, and his motor-generator. I've seen it. I believe it. But I sure don't understand how it is possible.

Late news: The magnet motor has been issued a US patent (#5,436,518). In the accepted patent claims the input power to run the motor was 19.55 watts and the output of the generator was 62.16 watts. That's 318% output over input. So, though the system is obviously impossible, it not only works, but it's been patented. And I've ridden an electric scooter powered by the magnet motor-generator.

Stonehenge

On Saturday we skipped the free $18 English breakfast and went on a tour to Stonehenge. Sherry's been wanting to see the place. It was an all-l-l-day bus trip, which included stops at Bath and Salisbury. Our tour guide talked almost incessantly over the bus's PA system, giving us in a strident Julia Child's voice details of unmemorable significance on places we were passing as we drove clear across the country. We saw the rocks. No, I didn't get any feelings, other than some leg cramps and a tired bottom from sitting for hours on the bus. Don't miss Stonehenge if you go to England.

In Salisbury we visited a church where they have an original copy (is that self-contradicting?) of the Magna Carta. The Magna Carta room closed at 3 p.m....we got there at 5. Fortunately there was a symphony orchestra there practicing, so I got to show off my music recognition skills by identifying Richard Strauss's "Tod und Verklarung" for the other members of the tour group. Don't mess with me when it comes to classical music, okay?

The Fan Gets Hit

Sunday we returned home to New Hampshire. The BA meal was inedible. Sherry saved hers for the cat. I stopped by the office on the way home to pick up Friday's mail. Holy Jehosephat, there was a whole post office basket full!

On the Saturday morning before the trip I'd been interviewed for three hours by Art Bell W6OBB, who has a nightly talk radio show. I was on from 4 a.m. until 7, talking about amateur radio and other things.

I'd offered to send a 12-page booklet listing 49 books that people are crazy if they don't read to anyone requesting it. I also offered the 16-page instruction booklet on the blood purifier and a 32-page booklet of editorials I've written for *73*, but haven't had the space to run yet. I figured I'd maybe get a couple dozen requests.

Well I figured wrong. I began to suspect that when my fax machine started running through rolls of paper like a Broadway ticker-tape parade within minutes of the end of the program. Two weeks later it was still grinding out responses to the program. My 800-number at the office was lit up for a week. And then the mail started. It was only a dribble on the Wednesday I left for England. On Friday there were 257 letters.

I spent the rest of Sunday after getting back answering the requests with information on amateur radio, cold fusion, the book list, editorial packages, and blood purifier circuits.

The Monday mail was even worse. Whew! It tapered off a little on Tuesday and was down to only 60 letters by Wednesday. Helen, at the office, worked flat out making photo copies of the booklets, trying to keep up with the demands. By Friday I got 'em all answered.

By then the second wave had started to arrive. These were the orders for booklets resulting from my answers to the first requests. Subscriptions to *73* and sample copies of *Cold Fusion*. Orders for my submarine adventures in WWII book. Lots of orders for my *Declare War* book.

If I can get on a few more talk shows maybe we could get amateur radio growing again. But how about you? How about you leaning on any friends you have with talk shows to talk up our hobby. Explain how there is no such thing as a lonely ham. You turn on that switch and the whole world is yours. You turn it off and you're back alone again until you need company. Most of my friends down through the years have been hams I met on the air. Johnny Williams W2BFD, the guy who made RTTY happen. Sam Harris W8UKS/W1FZJ/W1BU, who pioneered moonbounce. Bill Hoisington W2BAV/K1CLL, who built circles around everyone else in the hobby for years. Chuck Martin WA1KPS/K1IO, who skied with me and went on diving trips for years.

Kids may not appreciate the entry into high-tech careers that amateur radio provides, but maybe their parents, who see the way the world is going, may encourage them. Ham radio did it to me and I don't regret one minute of it.

Amateur radio has provided me with a lifetime of adventure and unlimited career opportunities. Ham radio got me my first job as a technician at GE, testing the BC-191 and BC-375 command transmitters, back

Monitors

If you've been to any hamfests in the last five years, you undoubtedly have noticed that they tend to be filled with more computer gear than radio equipment! I suspect most hams are computerniks, and the two do go together rather well. Although I see lots of PC clones and even a few Macs, the one thing I see more of than anything else is monitors. There are all kinds of monitors at bargain prices, including monochrome, CGA, VGA and SVGA. Some have coarse dot pitches, which may be the reason the seller is getting rid of them. Others may have nice, .28-mm dots, making them excellent choices for today's high-resolution computer displays. How can you discern the dot pitch? It takes a little practice to get good at judging them, but there are two ways to tell: First, look at the monitor's model number. Usually, the last numbers in it give the dot pitch. So, an SV 29N has a .29-mm dot pitch, which is pretty good. A VL-4539, though, would have a .39-mm dot pitch, which is pretty ugly. If there's nothing obvious from the model number, take a good look at the screen. With a working monitor, it should be quite clear whether the image is made of fine dots or not. If the set is dead, though, you can still get an idea by shining some light on the screen and looking closely. If you see an obvious, square, blocky pattern, chances are the unit has an unacceptable dot pitch. If, though, you see tiny dots, and especially if they're not easy to make out, you've probably got a good, fine pitch and will be happy with the monitor. That is, if you can fix it!

Alphabet Soup

VGA? CGA? EGA? SVGA? RGB? Hercules? Multisync? Unlike with regular TV sets, there are lots of different signal standards for computer monitors, and the one you buy must match your computer's signal or you're out of luck. What do you need? Most PC clones today use VGA and/or SVGA. If you have an old XT, it may need CGA. Take a look at the video connector. If it's a nine-pin, it's probably CGA, although it could be Hercules. If it's a high-density 15-pin, chances are it's VGA/SVGA. Naturally, be sure the plug on the monitor you're looking at matches the one on your computer!

If you're a Mac user, you have several options. although Macs are made for use with Apple monitors, which have a different scan rate from the IBM standard, many multisync monitors will work, as long as you procure or make the required plug adapter. Even better, many newer Macs can use regular, non-multisync VGA and SVGA monitors! All it takes is a plug adapter cable wired with a specific connection that tells the Mac it's connected to a VGA monitor. From my experience, even many Apple dealers don't know that. Not all Macs can do it, though, so check the manual for yours before investing in a VGA monitor. If it will work, you can save quite a bit of money, because VGA monitors cost a great deal less and are much more easily found on the surplus market.

Pick One

If you want to pay $100 to $150, you can get a monitor that works fine. Even in that price range, though, take a good look at the picture before you buy; some of those sets have been on for thousands of hours and have weak CRTs, and others have crummy dot pitches. What you see is what you will have to live with, so choose carefully, remembering that you can have a new monitor with a .28-mm dot pitch for about $225 to $250 if you're a careful shopper. In general, avoid old looking, dirty, beaten-up units, as you would with anything else. If it looks like it's spent its life in a dirty warehouse, it probably has, and you would best avoid it.

R.I.P.?

How dead is dead? If you want a monitor for $10, don't expect it to work at all. Probably, the power light won't even come on. Often, the seller will tell you that he doesn't know if it works, or that it worked the last time he tried it, but it's been awhile. Take that as hamfest code for "it's dead!" Surprisingly, there seem to be lots and lots of dead monitors out there! So, let's take a look at what you can expect to find, and how best to go about fixing those cheap, dead monitors.

Just a TV

Really, a computer monitor is nothing more than a TV set. There are a few differences, however. First, there's no tuner. Second, all that NTSC color decoding circuitry is gone—modern computers send their red, blue and green signals on separate wires. Third, there usually is no sound circuitry. So what's left?

Just the nasty stuff! A typical computer monitor consists of a power supply, horizontal and vertical scanning circuits, a high-voltage supply for the CRT, video output amplifiers (one for each of the three colors) and, of course, the CRT assembly itself, with the yoke and convergence magnets. Generally, the convergence, which is what keeps the three colors aligned with each other on the screen, is static. That is, it is accomplished by nothing more than a group of magnets around the neck of the tube. If it's a really big monitor, say 17 inches or more in screen size, it could have dynamic convergence, which is done with a bunch of circuits that generate some extra currents which are used to adjust the convergence as the beam sweeps across the screen.

Most television problems occur in the power supply, scanning and high voltage sections, so the lack of all those other circuits doesn't help us much here. Most of the dead monitors I've bought have had either blown power supplies, blown horizontal output transistors, or both. Assuming your monitor exhibits no signs of life at all, it's best to start with the horizontal issue.

But First

Before we do, though, I must warn you about something: The insides of TV sets are extremely dangerous! A typical color CRT requires about 30,000 volts at its anode (yes, you read that right!), and other voltages ranging into the thousands at other terminals. There's plenty of current, too, so you can be killed if you're not careful. Also, the picture tube itself is fragile enough that you can break it with a dropped tool, and its high internal vacuum can make it implode like a bomb, causing just as much personal injury as an explosive device. Be *careful!* Always shut the power off and pull the AC plug before disconnecting or replacing anything, and try to avoid disconnecting the anode lead from the picture tube. If you absolutely must do that, remember that the tube is basically a big capacitor which can store enough high voltage to finish you off. Discharge it by connecting a clip lead to the set's chassis and then connecting the other end to a screwdriver with an insulated handle. Now, touch the tip of the screwdriver to the inside of the dimple where the anode clip was, and hold it there for about 10 seconds.

Pop Goes the Output

Nothing in any TV set works as hard as the horizontal output transistor, so nothing blows out as often, either. This is a special, high-voltage, high-current transistor which generates not only the horizontal scanning signal, but also the high-voltage supply for the anode of the CRT. In some sets it generates many of the lower voltages as well. You'll find the part clamped or screwed to a big heat sink which is nearly always right next to the flyback. What's a flyback? That's just an old TV service shop name for the high-voltage transformer. It's easy to locate because its output lead is the thick one that goes to the side of the picture tube. Follow that lead back and you'll find the flyback and the horizontal output. Because they're multi-layered inside, horizontal outputs have a great deal of voltage drop and usually won't test properly on an ohmmeter or a garden-variety transistor tester, so don't bother to try. When I get a dead monitor,

Radio Direction Finding

Joe Moell P.E. KØOV
PO Box 2508
Fullerton CA 92633

New T-Hunting Goodies

"You never know where you'll end up and you never know what you will find." That's my standard answer when someone asks why I still enjoy hidden transmitter hunting after doing it regularly for almost 20 years. The outcome of a radio direction finding (RDF) contest (usually called a T-hunt or foxhunt) is seldom predictable. Hiders have an endless variety of places to put radio foxes, and they're always coming up with new ways to disguise them.

You may have to drive several dozen miles in the right direction to get to the hidden T site, but that doesn't mean it will be in plain sight when you arrive. Sometimes the greatest challenge comes when your car reaches the end of the road and you have to finish on foot. You need good RDF gear for this part of the hunt (sometimes called the "sniff"), because your eyes can be deceived.

On one of my first transmitter hunts, the signal led me to a street of new homes in Phillips Ranch, California. Each had a very large front yard with a rural mailbox at the curb. The hider and his distinctive jeep were nowhere to be seen and no radio gear or antennas were visible. Several T-hunters were wandering around, finding nothing out of the ordinary.

RDFers who performed careful close-in triangulation while rolling their cars slowly down the street soon discovered that the signal was very strong in the vicinity of one mailbox. Upon closer inspection, they realized that the name on the box was "T. Hunter" and the transmitter was inside! Hider Rich Krier N6MJ had put a handie-talkie, battery pack, and tone box into a standard rural mailbox, then painted and placed it to look like all the others. He had drilled a hole from the box interior into the 4" x4" wooden mounting post and lowered the antenna into it. The whip was perfectly concealed, yet it put out a good signal.

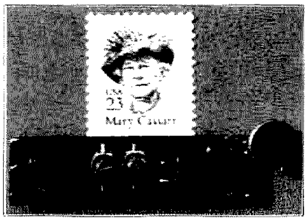

Photo A. The Agrelo Engineering HPVFC micro-transmitter is factory-tuned into a 50-ohm load with the trimmer capacitors on this side of the board. On the other side are 46 SMT components.

Since then I have enjoyed the fun of hiding tiny transmitters in unexpected places and watching T-hunters try to find them. This kind of T-hunt is popular all over, as evidenced by a recent Internet posting by Bruce Paterson VK3TJN. It told of a November 1995 hunt near Melbourne, Australia, that was put on by VK3VR, VK3MZ and VK3TVB, the current Australian champions.

VK3TJN wrote, "Any observers watching the conclusion of the next event would have seen a number of hounds madly rummaging around in shredded wood surrounding a climbing frame in a playground. Those with keen eyes would have noticed that a nearby wooden log had a hairline crack around it, as it had been hollowed out to fit a small transmitter inside. Four teams had managed to recognize this and then check in, before the cry of 'It's in the log!' from one jubilant hound shattered the silence."

Move Over, 007

Today's Surface Mount Technology (SMT) has made it possible to shrink a fox transmitter to the size of a pack of gum. The N6MJ mailbox trick could now be done with the entire transmitter inside the post. Hunters opening the mailbox door would see nothing at all!

"Homing In" for May 1993 featured construction plans for the smallest 2 meter FM transmitter board I've seen, designed by Ken Bauer KB6TTS. Small enough for two to fit side-by-side on an Elvis stamp, it puts out about 25 milliwatts with a 9-volt supply. I keep this transmitter, plus a tiny CW ID unit (reviewed in "Homing In" for August 1993) and a 9-volt transistor radio battery, in a small pill bottle. It goes with me whenever I talk to a ham club about T-hunting. Usually somebody hides it nearby and everyone gets a chance to try on-foot foxhunting with their handie-talkies and the "body shield" technique.

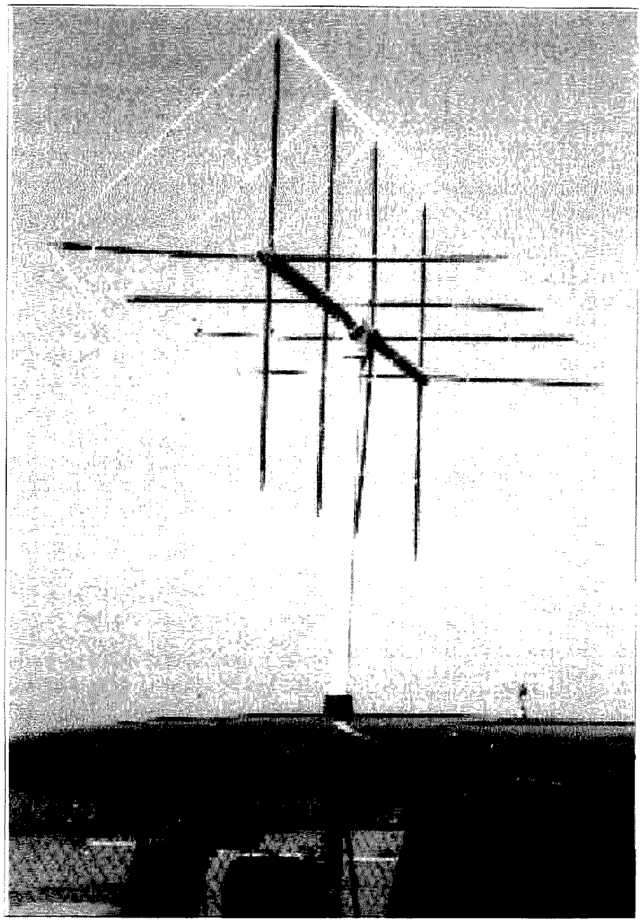

Photo B. The Cubex Yellowjacket four-element 2 meter cubical quad received a thorough test on my T-hunting van.

This tiny T has been one of the most popular "Homing In" projects to date. One ham who was especially impressed by it is Joe Agrelo N2OOC. He is the owner of Agrelo Engineering, a company that specializes in electronic design and manufacturing. "Mainly we do custom designs involving our digital voice recorder boards for clients around the world," he told me. "Our advertised products extend from my personal interest in amateur radio and a fascination with RDF."

Joe decided that a micro-T would be a good product to start his line of RDF gear. He realized that 25 milliwatts is fine for short range or high elevations, but most T-hunt scenarios demand more. "We built a few of the tiny Ts and had lots of fun, but they lacked the power we were looking for," he says. "Ken Bauer seemed to be a good choice to design a higher-power T for us and he agreed to do it."

By the time solder fumes cleared in the Agrelo lab, two models were ready to sell. Both are crystal-controlled with true FM modulation of the oscillator stage. Each includes an electret condenser microphone and high gain audio amplifier. There is a high-level (1 to 2 volts peak-to-peak) audio input also, to mate with your favorite "foxbox" tone generator.

At 1-1/2" x 9/16", the model VFC400 is only slightly larger than the 1993 "Homing In" project. With a 6-VDC supply, the unit I tested put out 190 milliwatts while drawing 140 milliamps. Four AA cells will power it for 20 transmitting hours. At the end of that time, the batteries will have sagged down to about half voltage, giving only 80 milliwatts output.

All hams seem to have inherited the "more power" gene, so it was natural for N2OOC and KB6TTS to

Continued on page 84

NEVER SAY DIE
Continued from page 77

in 1942. Ham radio got me into the Navy as a Radio Tech, and then as an Electronics Technician. And that got me plenty of adventure on a submarine during five war patrols. After college it got me my first job with radio station WEEB in North Carolina. Fellow RTTYers got me jobs later as the Secretary of the Music Research Foundation (where my classical music background helped), and working on a color organ Guggenheim Grant project for the Guggenheim Museum on Fifth Avenue.

It got me my first job in publishing as the editor of *CQ*. Most old-time hams have similar stories to tell.

So let's get out there and talk up our hobby and get the kids to think in terms of getting a ham ticket instead of the dead end of CB.

If you can't handle a talk show interview, at least see if you can get me connected. I can talk for hours. And hours. Did I tell you about the time I talked two hams into going on an African hunting safari with me? Robbie 5Z4ERR talked me into it on 20m. Wow, what an adventure that was!

If you've had some exciting ham adventures, why not grab your word processor and write? If I don't have enough room in *73* for all the stories I might make 'em into a book we can send to prospective hams to get their juices going.

"When you're running a ham club you are in show business."

How about the time I got 73 hams to go with me on a tour of Europe, with hamfests in London, Paris, Geneva, Rome and Berlin? Boy, did we have fun! We still talk about it when, at hamfests, I meet the hams who were on the trip with me.

And if you can't get on a talk show, at least get around to your local schools and talk to the fifth- and sixth-graders and get them excited.

Ham Club Woes

Between the ultra-bad band conditions of the last couple years, mainly the result of our not spending more for sunspots, and the continuing drop in the number of active hams, I'm seeing more and more anguished articles in club newsletters, hand-wringing over the club's disintegration. There are the usual complaints of no volunteers to help, fewer members coming to meetings, and so on.

My message is simple: Stop your bitching and breathe some life into your club. One fact of life is that very few club members ever have or will volunteer to do anything...unless you get them excited and involved. Most clubs are kept together by one to three spark plugs. It really only takes one to make a big difference.

Let me ask a direct question. How exciting are your club meetings? I've been to far too many clubs where the meetings are deadly bores. Where the president doesn't know any better than to allow business discussions to waste meeting time. If someone in the club has an unstoppable need to have business meetings, at least have them handled by a small "executive committee" and keep club business out of the regular club meetings. All you need is a short report from the executive committee on their actions.

I remember when the Nashua (NH) club spent an entire Friday evening discussing what color to paint the club building. That one bomb discouraged at least 10% of the members from coming again. It wasn't long before the club had no further need for their building and had to give it back to the city.

When you're running a ham club you are in show business. Meetings have to be fun or you'll lose your audience. Every meeting has to provide enough benefits to every member to get them to come back again. Otherwise you're up against Strange Luck, the X-Files or a movie. You have stiff competition, so you'd better put on a good show.

Benefits?

When's the last time you had a club member put on a slow-scan show and tell? Satellite communications? Packet? RTTY? Have you been giving your DXers an opportunity to show off their latest hot QSL cards? Certificate hunters their trophies? Have you invited a nearby ham dealer to tell you about some of the crazy things he's run into doing business with hams? Are there any ham manufacturers within driving distance?

You need interesting speakers. If you can't get them directly, maybe you can get them to do a video talk-to show to the club.

Speakers?

Here's the rules for speakers. If they're coming in from any distance you should offer to pay their transportation costs. Get three or four club members together for a dinner before the meeting. If your speaker has to fly in, meet him at the airport. Drive him to the hotel where you've reserved a room for him.

Whether the speaker is local or imported, make sure that he is the big deal at the meeting. I've given talks to scores of clubs and more than I like to remember had endless business meetings before it was time for me to talk. By then most of the members were just about asleep. Thanks, fellas.

If you're going to have elections, for heaven's sakes don't have a speaker that night too. That's happened to me at least a couple dozen times. Along about 10 p.m. I'm given the floor. By then I need a cherry bomb to wake 'em up.

The speaker comes before the coffee and doughnuts, too. Coffee is supposed to be a stimulant, but in my experience the only thing it stimulates at meetings is sleep.

If you find any outstanding speakers please drop me a note so I can pass the word along for other clubs. Alas, we don't have nearly enough good showmen among our manufacturers.

How About Me?

Probably not.

When I signed on as the editor of *CQ*, back in 1955, I was asked to speak at some hamfests. Whooee, did I have stage fright! When I got up to talk, my mind would go blank. A few hundred talks later I really enjoy giving talks and I almost never plan ahead. I just wing it, and generally keep everyone laughing. Well, look at all the really stupid things that we hams take seriously. Like the Honor Roll, the "need" to work a new DX station, the pompous foolishness Glenn Baxter airs endlessly, the garbage on 14,313, repeater jamming, the importance of the CW test to weed out the CBers, and so on.

The best ham raconteur by a wide margin is Jean Shepherd K2ORS/4, if you can coax him away from Florida. Try dangling $1,000 and trip expenses and see if that'll break him loose. He's worth every penny. All you have to do is get around 300 hams to pony up $10 each and then promote the heck out of the event.

"Our eating and drug habits are generating a wonderful $1 trillion business."

These days I don't have much time available to address hamfests or clubs. If I did have the time I'd like to get on the air more, and maybe visit a few more countries. There's still a bunch I haven't visited yet. But I've thinned down the *73* staff and am doing a lot more of the editing myself, which really eats up the time. Well, I wasn't happy with the way the magazine was going, so I decided to clean house a bit and run things myself for a while. I hope you'll begin to see some improvements. All this while the cold fusion field is really heating up. I've even had to turn down a speaking request in Russia. But just keeping up with the profusion of papers being generated in the cold fusion field is a serious time user.

Anyway, let me know what speakers you've had at your clubs that you recommend so I can pass on the word.

Tech Sessions

How about providing a half hour or so of theory before the regular meeting? There are few club members, young or old, who wouldn't benefit from this. Heck, you might even set up some code practice sessions before the regular meeting...one at 13 per and the other at 20 per. Teach 'em using my system. You can even talk to the group while they are copying, thus making sure they are copying automatically, and not trying to translate the dots and dashes.

Your Mercedes

If you've followed ol' Uncle Wayne's advice and started your own business, one of these days you'll be thinking of buying a Mercedes, Jaguar or Porsche. The Mercedes is a good investment because it's so well designed and built. The darned things often last for half a million miles, if you treat 'em right.

That means not using old crankcase oil for the engine, or tap water to refill the battery. It means not putting iron filings or sugar in the gas tank. It means cleaning and polishing it now and then. If you've ever seen a concours d' elegance contest, you've seen 20- and 30-year-old cars that look showroom-new.

Why should I make such ridiculous suggestions? You'd never treat a $50,000 or so car that way, right? So why would you care more about your car than your body, which is infinitely more complex and valuable to you? If you make enough money you can always replace even the most expensive of cars. But you get only one chance with your body. If you screw it up, there's no replacement, no matter how much money you make. Think about it. If you care to look at the instruction book for your body you will find big bold warnings against fueling it with Big Macs, fries and Coke. Worse, you not only are putting metal filings in your fuel system, you're encouraging your children and grandchildren to prematurely destroy their bodies too.

If you think I'm exaggerating, just take the time to go to a hamfest and take a good look around! These guys are busy reducing the expected life of their bodies from a vigorous 100 years to a sickly 50 or 60.

No, don't turn to your doctor for the instruction book. Up until a few years ago most doctors smoked, showing how little attention they've paid to the maintenance of their own bodies. Cigarettes were called "coffin nails" back in WWI, so there's never been any real secret about their destroying the body.

How many people in their 60s or 70s do you know who are in robust health? Well, the bright side of all this is that we're keeping the doctors and hospitals busy. Our eating and drug habits have generated a wonderful $1 trillion business and some

Continued on page 82

NEVER SAY DIE
Continued from page 77

great recent hospital TV programs.

We start right off by feeding our kids formula, thus partially crippling their immune systems for life. Then we zap them with so-called immunization shots, which further permanently screw up their systems. We fill their teeth with the deadly poison mercury, which then slowly leaches into their systems. And we take them to McDonalds and teach them to eat crap. We buy them sugar-frosted garbage for breakfast. Boo Berries?

"Fluoridation is doing everyone exposed to it serious harm."

There goes Wayne again? Hey. I've given you the references on all the above so you can do your homework. Please don't take my word for any of this. Do your own reading. I've read hundreds upon hundreds of books, and I've reviewed those for you that I've found the most authoritative. If you haven't kept track of my reviews, I've put them together in a booklet describing the books I think you are crazy if you don't read, together with the sources, if they are not likely to be available from your local library. No, I don't sell them through Uncle Wayne's Bookshelf. Oh, I considered it, but then I'd be accused of trying to make money with my recommendations. No, you're going to have to get these books on your own.

I mentioned my list during a recent radio talk show interview and got over a thousand requests for it. Then came the follow-up letters thanking me for doing all that research, and telling me how wonderful the books are I've recommended. You can have my list for $3 plus a 6x9 envelope with a 32¢ stamp on it. If you don't have an envelope, then make it $4 and I'll address it to you and put on the postage. Send cash or check to Uncle Wayne, 70 N202, Peterborough NH 03458-1107. If you order at least $10 worth of stuff you can use a credit card, and even call in your order. Like a subscription to *73*, for instance, or a couple more of my booklets, or even my *Declare War* book.

If you ruin your Mercedes you can always buy a new one. If you ruin your body, you'll have to reincarnate to get a new one. Think about that the next time you buy a six-pack.

Death By Government

The more I read about the things our government is doing to us, the more discouraged I get. Not just that it's happening, but that we, the people, let it happen in the first place, and then, even after we find out about what's happened, we don't made any serious effort to stop it. I've written about how our government is allowing our dentists to continue to put dental amalgam in our mouths, and our children's, even though it's 50% mercury, which is acknowledged to be a deadly poison, which is causing terrible health problems for millions of people. I've written about vaccinations and the trail of death and sickness they're leaving, with there not being one shred of scientific proof that they work.

When I was a lot younger I remember the fight a few extremists put up against our city governments fluoridating our water. Bunch of kooks, we were told by the media. Well, I know you're not going to believe this, but it turns out the kooks were right, for a change. There are any number of scientific studies which show that (a) fluoridating us does not help fight tooth decay, and (b) the fluoridation is doing everyone exposed to it serious harm.

Sure, only a small percentage of the children who get their teeth swabbed with a fluoride solution by dentists or their dental assistants die from it. I suppose that's an acceptable loss, as long as it isn't your child. And it's not enough so the doctors can't cover it up to avoid lawsuits.

In areas where the water has been fluoridated the cancer rate has increased substantially. In high fluoride areas the people age prematurely, their teeth drop out, and their bones get very brittle. Even minor shocks can cause a hip fracture, which in an elderly person is virtually a death sentence.

How about the three-year-old child who had his teeth swabbed at a clinic? The nurse gave him a glass of water to rinse out his mouth and turned away to gossip with someone. The child drank the water and was dead in a few hours.

There goes Wayne with his hyperbole of gloom and doom, right? Hey, don't believe me. But do get a copy of *Fluoride, The Aging Factor*, by Dr. Yiamouyiannis, Health Action Press, ISBN 0-913571-03-2, 292p, $15, and do your own homework. He's got all the research data there for you. I'm not exaggerating. I'm understating the situation. Yes, your government is, in many cities, pouring this poison into your water supply. And this poison is not only causing a wide range of illnesses, it is also causing chromosomal damage which is then passed on to the next generation. Cities and towns are adding from 0.6 ppm to as high as 8.0 ppm of fluoride to your water.

How do you get away from it? A home still helps. I've been drinking distilled water for some time now, and am getting my own still. How about Coke? The stuff is packed with fluoride (2.56 ppm). So is Diet Coke (2.96 ppm, and it only takes 0.5 ppm to cause serious trouble). And it has aspartame, to further derail your body's ability to cope with life.

Freedom

For a country that prides itself on and preaches freedom, we have an awful lot of tyranny going on. I think I can even make a good case for liberals being disciples of the Devil. All those things that our beloved government legislates "for our own good" are my beef.

Like what? Like vaccinations, fluorides in our water supply, seat belt laws, helmet laws, and so on. I've written about vaccinations, which besides not working, are causing life-long health problems for many people. Ditto fluorides in our water. I wish that Congress and the state legislatures would stop using the law to do things for my good. All I need is the information and then the freedom to make my own decisions.

Sure, seat belts save lives, but if I'm dumb enough to not use them, then that should be *my* decision. Mother Nature (aka God) has a system that has worked for millions of years. Billions. It's called natural selection, or the survival of the fittest. So if I'm dumb enough to not wear a helmet on my scooter or a seat belt, if I get killed that will tend to weed out that kind of dumbness. By forcing me to live longer and thus be able to have more children, the government is going against God and weakening the human race.

How about so-called Social Security? It was originally set up as a way for the government to take in more money, pretending it was insurance instead of increased taxes. It's still taking in billions more than it's spending and Congress is "borrowing" the surplus and spending it. If it was a voluntary system I'd have no complaint. But it's mandatory, and that's not my idea of freedom. Sure, it's "for my own good." If I'm dumb enough not to provide for my old age, the government will support me. The result of that is that a lot of people don't provide for their old age in some other much cheaper way.

Water, Water, Everywhere!

And not a drop to drink. Well, not a drop that's safe to drink, anyway.

I've written about how we're slowly poisoning ourselves in various ways, all complete with references so you can completely disbelieve what I'm reporting and go to my sources. All I can do is lead you to the fountains of information. I can't force you to read. But at least, for those of you who have any interest in living long and in good health, I'm pointing out the path. Of course, if you prefer to smoke, eat crap, and couch-potato away your life, that's your choice.

Now, about water. My thanks to Emory Schley N4NCU, who dropped me a postcard suggesting I call Acres USA and get a copy of *The Choice Is Clear*, by Dr. Allen Banik. It's a 40p $2.50 book and worth a million bucks. Or whatever you feel your health is worth. Maybe 2¢ is closer, judging from the constipated 13-month pregnant potbellies I see walking around at hamfests. What a terrible thing to do to a perfectly good body! Heck, even when I was fat I never did *that* to myself.

Anyway, invective and insults aside. I got the book and loved it. I'd already read an excellent book on how the fluorides added to most public drinking water are causing serious illnesses. And I've seen references to the damage that the chlorine in our water is doing to us. But I thought that, heck, since I live on a farm with my own well, I was safe. Once I read the bad news in this book I sighed and started buying distilled water to drink.

You'll read about Dr. Bragg, who at 94 had the blood pressure of a 20-year-old. I seriously doubt you'll read this short book and not change to distilled water. The Dr. Banik book is available from Acres USA, Box 8800, Metairie LA 70011.

I've been lacing my distilled water with some of Pat Flannagan's Crystal Energy. But that's another story, and a fascinating one. I'll go into the details for you, complete with where you can get some of his magic elixir.

My water bill is mounting and I'm up to here in gallon water bottles, so I've got to shop around and see where I can get a still and make my own water.

The more research I do, the more I'm convinced that if we'd eat right, drink pure water, avoid EMFs, get rid of dental amalgam, avoid immunizations, and breathe clean air (such as we have in abundance in New Hampshire), we'd have a good shot at getting a mention by Willard Scott on the "Today Show." Of course, if you prefer that you and your family be crippled by arthritis, Parkinson's, cancer, diabetes, high blood pressure and so on, that's your choice. My dad chose to smoke despite anything I could say, so he had to spend the last 10 years of his life with an oxygen bottle at his side because he only had 5% of his lungs left working. Imagine not being able to really breathe for 10 years! He smoked Camels. Didn't the Marlboro Man die of cancer? Or was it emphysema? My grandfather, who smoked cigars, died in his 50s as a result. So did my uncle. And, unless the medical establishment puts out a contract on me for spoiling their business, I intend to keep writing my editorials for another 30 years. Or so. 73

Making Your Club More Exciting

How the BARA broke out of its rut.

Dee Interdonato NB2F
118 Westervelt Place
Lodi NJ 07644

Sometimes clubs stagnate with business meetings; the more active and creative members become discouraged, and stop attending meetings.

A few years ago, The Bergen Amateur Radio Association (BARA) was in just such a rut. We got to brainstorming as to how we might give our membership some fun, as well as show our local community commitment, *and* get some public exposure for amateur radio. With our 30th anniversary approaching, we wanted to cook up something special.

Since it was also the 300th anniversary of Hackensack and the 50th anniversary of the *Ling* submarine, where we'd successfully celebrated our 25th anniversary, we agreed on setting up another special events station on the *Ling*.

The plans for the special event kept us busy for the next few meetings, with excitement building among the club members. One member, Mike Surmick WA2QWM, was employed by the City of Hackensack (located in northeastern New Jersey), so he became our liaison with the city. In fact, he became the unofficial leader of our event and we used his call for the special events station.

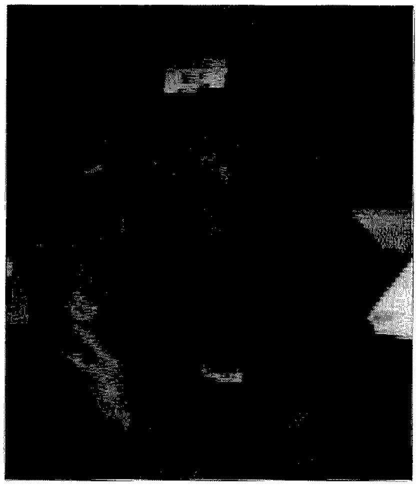

***Photo A.** L/R Vince N2AXV, John KC2EV, Mike WA2QWM, Dave N2IMC at the packet station.*

***Photo B.** Dee Interdonato NB2F (the author) operating in the* Ling *radio room.*

We contacted the *Ling* and informed them of our intentions. After our 25th anniversary there, they knew us well and enjoyed the publicity as well as the added revenue from visitors. Now all that had to be done was planning for the special event station equipment and operators, the food, and as much publicity as we could generate.

The setup began in the morning and operation started that evening. Bob Wilson N2RLI volunteered his RV full of ham gear, and our Field Day antennas were ready to go. WA2QWM, our special event station on board the *Ling* was on the air!

After many hours of operation, hundreds of QSOs on HF, VHF, UHF, packet, and satellites, after numerous demonstrations and handouts about amateur radio were given to the public, after vast amounts of food were consumed, and the cleanup was over, the certificate committee went to work. Chaired by John Chooljian K2KRF (a WWII radioman on an LST in the Pacific), the committee had the job of filling out and sending the certificates we had offered. Though the HF bands were not cooperating for DX contacts, many were made via our ham satellites, so we had plenty of foreign requests for certificates.

Since we had so many modes of operation, our club members had an opportunity to become exposed to them; it was a fine training event for us too! Although I am a satellite operator at heart, after the event I soon became active in packet.

The club members were given tours of the *Ling* and told some fabulous stories of submarine life and the history of the *USS Ling*, making this one of our club's finest events. Obviously, all ham clubs don't have access to a submarine for a special event, but if you look around you might find an old steam locomotive, a historic building, an airfield, etc. But the location of the event isn't the most important thing. It's getting your club involved that will keep interest in your club high, and help promote our hobby with the public. We helped a submarine association and maybe you will help another historical society, a hospital, or a library. With Congress cutting back on pork, keeping important places, things, and moments in history alive will help promote amateur radio and provide a good public service. 73

HOMING IN

Continued from page 79

attempt to squeeze out even more RF. This resulted in the model HPVFC, with a beefier final stage transistor. The HP stands for high power, of course. Final stage gain is the same, so I measured the same power output at 6 VDC as the VFC400 produced. However, the HPVFC can safely operate from a 9-volt source, which produced 300 milliwatts for me.

No Microscope Required

Photo A shows an HPVFC as it comes from the shipping box. It's about a half-inch longer than the VFC400. The Agrelo micro-rigs aren't kits, but they aren't plug-and-play either. All the hard work of mounting the dozens of tiny SMT parts has been done and the assembly has been tested and tuned. You must provide your own enclosure and solder in the wiring and connectors of your choice for antenna, power, and audio. Be careful, as there is no protection from damage due to reversed power polarity.

An important thing to consider in evaluating a fox transmitter is how it behaves as the battery becomes drained. If you do a good job of hiding your T, the hunt will take awhile and you might not be near your transmitter when the battery begins to poop out. Some other rigs I have encountered go far off frequency (maybe out of band!) or develop an audio howl as the input voltage is cut in half. They are completely unsuitable for use in an unattended station.

The Agrelo Ts that I tested scored well in this regard. The HPVFC audio remained clean as voltage was reduced to 1.8 volts. Below that, the oscillator shut off. Carrier frequency shift from 3 to 9 volts was 2 kHz. (Unfortunately, no frequency adjustment trimmer is provided.)

Even a QRP hidden transmitter has to be spectrally pure, because it may get hidden near an airport or other sensitive location. Remember, the second harmonics of a 2 meter signal are on frequencies used by aircraft! Hiders in Southern California like to put Ts on top of mile-high mountain peaks, where a few milliwatts can cover thousands of square miles.

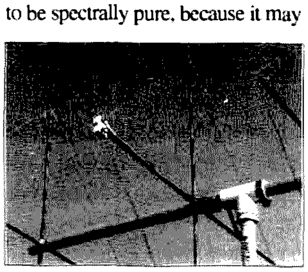

Photo C. The Yellowjacket quad is fed directly from RG-8X coax. About five turns of coax around the boom provide decoupling and matching.

There are some other transmitters being sold to T-hunters that have not been reviewed by "Homing In" because I have found them to be spectrally "dirty." Output filters aren't difficult to include in base and mobile transceivers, but when you're trying to make a postage-stamp-sized rig, it becomes much more tricky. Rather than ignore the problem and pass it off by saying "It's a kit," Agrelo Electronics bit the bullet and figured out how to include a tiny two-stage low-pass filter in the HPVFC. My spectrum analyzer check of the HPVFC found that all harmonics and spurs above the carrier frequency were down -52 dB or better, easily surpassing the FCC requirement of -40 dBc for low-power VHF transmitters.

For its small size, the HPVFC is amazingly rugged. However, the unit I tested did not have heat sinking on the final stage. With a 9-VDC supply, the output transistor got quite hot and power output dropped 20 percent in less than a minute. Besides the power decrease, high-temperature operation can dramatically shorten final transistor life.

For low-duty intermittent signal hunts (less than 10-second transmissions and at least a minute between transmissions), temperature should not be a problem. Otherwise, I recommend adding some heat sinking to the final stage for operation above 6 volts. For instance, you could cement the flat surface of a 1/2" x 3/8" finned sink to the trimmer side of the board, behind the final transistor. The layer of cement must be very thin for good heat transfer. After installing your sink, use a regulated power supply and check power output versus time for your planned transmission timing. If power output drops more than 10 percent, you need more heat sinking.

Two frequencies are available from stock: 146.565 MHz and 145.79 MHz. 146.565 has become the de facto national simplex T-hunting frequency, recognized by coordinators in Southern California and elsewhere. 145.79 is used in much of the USA for Automatic Packet Reporting System (APRS), as described in several previous "Homing In" articles. APRS enthusiasts are discovering that HPVFC is a good choice for use in miniature stand-alone trackers. Agrelo Engineering will crystal your HPVFC on another 2 meter frequency of your choice for an additional $30.

New Quad for T-Hunting

For a simple, inexpensive and effective mobile T-hunting antenna for 2 meters, it's hard to beat a yagi or cubical quad. Just rotate the mast carefully to peak up the incoming signal on your receiver's S-meter, and the front of the antenna will be aimed in the signal source direction.

A four-element 2 meter quad certainly does not result in a "stealthy" RDF system. Nevertheless, it is the antenna of choice for Southern California mobile T-hunters because its high gain makes it possible to track signals at greater range. Once you figure out how to support and turn the mast in the passenger-side window frame and armrest, you can be ready to go T-hunting in a couple of hours.

It's easy to make a lightweight RDF quad for your favorite VHF or UHF band using ordinary PVC plastic plumbing supplies from your local hardware store. However, lots of hams have asked me how to buy one ready-made. Ed Buchanan KN6CL of the Fullerton Radio Club saw this as a business opportunity.

Ed says he's a pipe fitter by trade, but he has always liked to build antennas, particularly quads. That's what led him to buy the Cubex Antenna Company from Karl Scharping W6KWF about a year ago. "Cubex has been in business for 39 years," Ed says. "I bought an antenna from Karl in 1992 and at that time I asked him if he planned to sell his business. He was in his mid-80s, but he said he had never thought about it. But he called me a few months later and said he was considering retirement. We got together and struck up a deal."

Cubex is best known for ruggedly-constructed "monster quads" for DXers. W6KWF had never sold antennas for bands above 30 MHz. KN6CL decided that for Cubex to grow, it should add T-hunters and other VHF enthusiasts to the customer base.

The new Cubex Yellowjacket four-element 2 meter quad (Photo B) is quite similar to the strung-wire quad in my T-hunt book (see the sidebar),

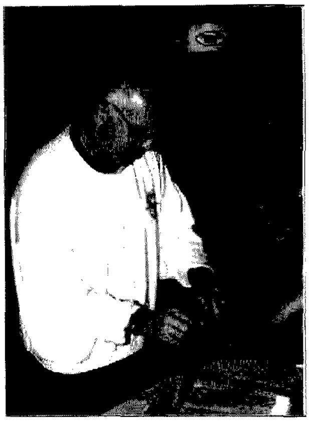

Photo D. At the factory in Brea ,CA, technician Ed Hocking AB6N (left) puts another ready-to-ship 2 meter quad kit into its bag with help from new Cubex owner Ed Buchanan KN6CL.

but Ed made some changes that make it more rugged. The boom is 1" O. D. tubular Fiberglas and the spreaders are quarter-inch-diameter solid Fiberglas rod. Elements are solid tinned copper wire. "I pre-stretch the wire when I make them so they are not going to sag," Ed says. All hardware is stainless steel.

For quickly changing wave polarization to match the signal (horizontal, vertical, or anything in between), the PVC boom-to-mast tee allows the boom to be rotated (Photo C). A worm-gear clamp adjusts the tension on this joint. You can slide the coupler as required to optimize mechanical balance.

Like Cubex HF quads, the Yellowjacket is shipped in kit form (Photo D). Color-coded tapes on the boom, spreaders, and elements make assembly quick and simple. You must provide the mast and coax. RG-8X is recommended for minimum loss and easy rotation.

The driven element is directly fed without a matching network. A coil of coax around the boom ahead of the driven element provides matching and decoupling. Adding turns to this coil moves the resonance point slightly higher in frequency. I found that five turns gave a near perfect match on 146.565 MHz.

I did far-field comparison tests of the Yellowjacket against my venerable stiff-wire quad, which I have used since I started T-hunting. This antenna (pictured on the cover of the T-hunt book) has nearly the same boom length and element spacing as the Yellowjacket, so I expected gain and

pattern to be quite similar. They were. Front-to-back, front-to-side ratios and 3 dB beamwidth were nearly identical. The forward lobe peak was squarely on axis.

The Yellowjacket had about 2 dB greater forward gain than my reference quad. Since gain and front lobe beamwidth are directly related (as explained on page 39 of the T-hunt book) and since both quads had nearly the same measured beamwidth, this was a surprise. Could it be that the oxidized wire on my old antenna has more loss due to "skin effect" than the shiny tinned element wire on the Yellowjacket? Guess it's time to retire the old quad!

I expected the thick-wall Fiberglas boom on the Cubex quad to make it noticeably heavier and harder to handle than the stiff-wire quad, but this was not the case. Of course, no mobile quad is completely safe from low-hanging tree branches, but this one should do quite well.

Now that Cubex has done the hardest part of making an RDF antenna for you, you should have no excuse for missing the fun of your club's next 2 meter RDF contest. See you on the hunt! 73

FAX (714) 577-9124

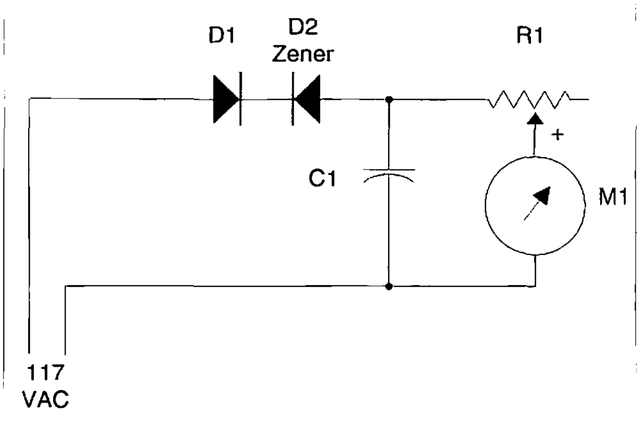
Yellowjacket 2 meter four-element quad $44.95 plus $6 shipping/handling. California residents add sales tax.

Construction plans and installation ideas for mobile strung-wire and stiff-wire VHF quads are in *Transmitter Hunting—Radio Direction Finding Simplified* by Joe Moell KØOV and Tom Curlee WB6UZZ. This 323-page reference book (TAB/McGraw-Hill #2701) covers all aspects of RDF and is available from Uncle Wayne's Bookshelf. #TAB2701 $19.95

UPDATES

In the January 1996 issue of *73*, we ran "Line Voltage Monitor" by J. Frank Brumbaugh KB4ZGC, beginning on page 86, without including Fig. 1, the circuit.

Here it is:



Number 85 on your Feedback card

HAM HELP

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full 8 1/2" x 11" sheet of paper. Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

If you are interested in amateur radio, and helicopter aviation, and would like to contact others with the same interests, there is a non-profit organization called "World Heli-Hams" that might be able to help. If interested, contact *Mr. Marden Pride, 34 Fountain St. A5, Haverhill MA 01830 USA. E-Mail: wb1ggi@gw.w1mx.ampr.org. Packet: WB1GGI @ K1UGM.#EMA.MA.USA.NOAM.*

Needed: Manuals for (1) IBM Portable PC Mod 5155; (2) CITIZEN 120D Dot Matrix Printer. *Peter A. Bergman NØBLX, 3517 Estate Dr. SW, Brainerd MN 56401. Tel. (218) 829-6286.*

Needed: Copy of alignment section of manual for HEATHKIT GR.78. I will pay for photocopies and postage. *Sam Cogar, P.O. Box 755, Houghton Lake MI 48629.*

Wanted: Manual and/or Schematics for the HEATHKIT SB-10 Single Sideband Adapter. *Roy Austin VE6RRA, Box 1388, Claresholm, AB Canada TØL ØTØ. Tel. (403) 625-4379. Compuserve 102215,1747.* 73

UNITED STATES POSTAL SERVICE STATEMENT OF OWNERSHIP, MANAGEMENT AND CIRCULATION [illegible]

ASK KABOOM

Continued from page 78

I just assume the transistor is bad. Luckily, they nearly always fall open, not shorted, so there's usually no other damage to the horizontal circuitry. Replacing the transistor is as easy as simply soldering in a new one. Be sure to use heat-sink goo if there was some on the old part. By the way, you can get these transistors at most parts houses and TV shops. Even Radio Shack sells them. Expect to pay between about three and seven dollars. Unlike with many other parts, you don't need an exact cross-referenced replacement. They're all NPN, and just about any horizontal output transistor will work in the average-sized monitor. But please don't even consider putting in any kind of transistor other than one made for horizontal output service; it won't work and probably will blow faster than you can hit the "off" switch, possibly doing further damage to the monitor!

Try It

Check the fuses in the power supply. If there's a bad one, change it. Now, give it a try! If you're lucky, your monitor will come to life. If you have a computer connected, you should get a picture. With no computer connected, the screen may remain completely dark, but you should hear that lovely high-voltage crackle, and touching the front of the screen should give you some static electricity. That means the horizontal and high voltage are working, and, most likely, so is the whole set. If it does work, take a look at the back of the picture tube to be sure the filaments are on. They should glow a dull orange.

Nada

If it still doesn't work, your task is not yet complete. Next time, we'll continue this topic, looking toward the power supply. Until then, 73 from KB1UM. 73

If time and/or money were not a factor, what ham equipment would you prefer? What would you do hamming-wise differently than you do now? Write: 73 Wish List, 70 R 202 N. Peterborough NH 03458

Barter 'n' Buy

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The 73 Flea Market, Barter 'n' Buy, costs you peanuts (almost)--comes to 35 cents a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to: *73 Magazine*, Barter 'n' Buy, 70 Rt. 202N, Peterborough NH 03458 and get set for the phone calls. The deadline for the April 1996 classified ad section is February 12, 1996.

WANTED: HAM EQUIPMENT AND RELATED ITEMS. Donate your excess gear, new-old-in-any-condition to the Radio Club of Junior High School 22, the Nation's only full-time, nonprofit organization working to get Ham Radio into schools around the country as a teaching tool using our EDUCOM—Education Thru Communication— program. Send your radio to school. Your donated material will be picked up ANYWHERE or shipping arranged, and this means a tax deduction to the full extent of the law for you as we are an IRS 501(c)(3) charity in our 15th year of service. It is always easier to donate and usually more financially rewarding, BUT MOST IMPORTANT your gift will mean a whole new world of educational opportunity for children nationwide. Radio's you can write off, kids you can't. Make 1996 the year to help a child and yourself. Write, phone or Fax the **WB2JKJ "22 Crew"** today: The RC of JHS 22, POB 1052, New York, NY 10002, 24 hours call 516-674-4072 or Fax 516-674-9600. Join us on the WB2JKJ CLASSROOM NET, 7.238 MHz 1200-1330 UTC daily, and 21.395 MHz from 1400 to 2000 UTC. Meet us at the upcoming Charlotte Hamfest. BNB762

PROPAGATION

Jim Gray W1XU
210 Chateau Circle
Payson AZ 85541

Old Sol is staging a surprise for all of us! The first spots of solar cycle 23 have appeared about 30 degrees north (and south) of the sun's equator, along with old spots of Cycle 22 near the equator. The polarities of Cycle 23 spots are the opposite of those of Cycle 22 spots. It looks as if Cycle 22 will be—or has been—shorter than normal (about 9.5 to 10 years instead of 10.5 to 11.5 years), as I suggested more than a year ago.

In fact, it is possible that the sun spot minimum may occur as early as June this year, accompanied by rapidly increasing solar flux levels not long thereafter. The "up" side plot of solar flux values for any cycle is usually steeper than the "down" side plot, so rejoice!

10-12 Meters

February is shaping up as a very good month for DXers, I think. The *best* days (G) are Feb. 1 to Feb. 4, and Feb. 12 to Feb. 21. The *worst* days (P) are likely to be Feb. 7 and Feb. 8, and Feb. 24 to

FEBRUARY 1996

SUN	MON	TUE	WED	THU	FRI	SAT
				1 G	2 G	3 G
4 G	5 F	6 F-P	7 P	8 P	9 P-F	10 F
11 F-G	12 G	13 G	14 G	15 G	16 G	17 G
18 G	19 G	20 G	21 G	22 G-F	23 F-P	24 P
25 P	26 P	27 P	28 P	29 P		

29. Yes, that's right, this is leap year, and February has 29 days. On Good days, the higher bands will be open longer and signal strengths better than last month, as we approach the Spring equinox, and you may find some surprising and welcome activity on 10 and 12 meters.

15-17 Meters

The 17-meter band has been quite good all through 1995, with some excellent openings—at times very much like 20 meters. I expect this will improve in 1996, and you may see 15 meters come alive, too.

20-160 Meters

Twenty meters, as always, will be your dependable DX band, while 30 and 40 continue their excellent winter ways, as do 80 and 160, but these latter two bands will soon begin to show signs of Spring with (QRN) and a poorer Signal-to-Noise ratio. 73

Payment for submitted articles will be made upon publication. Please submit both a disk and a hard copy of your article (IBM or Mac formats), carefully checked drawings and schematics, and the clearest, best focussed and lighted photos you can manage. "How to write for 73" guidelines are available on request. US citizens must include their Social Security number with submitted manuscripts so we can submit it to you know who.

On the cover: Peter Summers N2XTT shared with us a few of his QSL cards to make our attractive cover this month. We are especially interested in his creative card made for Jordan . See story on page 10.

Feedback: Any circuit works better with feedback, so please take the time to report on how much you like, hate, or don't care one way or the other about the articles and columns in this issue. G = great!, O = okay, and U = ugh. The G's and O's will be continued. Enough U's and it's Silent Keysville. Hey, this is *your* communications medium, so don't just sit there scratching your...er...head. FYI: Feedback "number" is usually the page number on which the article or column starts.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by 73 Magazine. 70 N202, Peterborough NH 03458-1107. The subscription rate is: one year $24.97, two years $44.97; Canada: one year $34.21, two years $57.75, including postage and 7% GST. Foreign postage: $19 surface. $42 airmail additional per year, payable in US funds on a US bank. Second class postage is paid at Peterborough, NH, and at additional mailing offices. Canadian second class mail registration #178101. Canadian GST registration #125393314. Microfilm edition: University Microfilm, Ann Arbor MI 48106. POSTMASTER: Send address changes to *73 Amateir Radio Today*, 70 N202, Peterborough NH 03458-1107. 73 Amateur Radio Today is owned by Shabromal Way Ltd. of Hancock NH.

Contract: Even the most cursory glance at this text is sufficient to bind you, morally and legally, to take a kid (or kids) along on Field Day, get 'em fired up on amateur radio, and then help 'em get started toward a license. You'll feel good about yourself and our legal cousel won't have to hassle you.

NEVER SAY DIE

Wayne Green W2NSD/1

Wanted: Role Models

A Silent Key note, sent in by a friend of the deceased, cited the wonderful things the SK had done. My reaction was one of frustration and disappointment. Why in blue blazes did this "friend" wait until the guy died to write something nice about him?

One of my readers recently sent me a tape of a "Nova" program about Dick Feynman, the Nobel Prize-winning physicist. I'd seen the program when it originally was shown, but it was fun to see it again. Too bad if you missed it. Even more too bad if you haven't bought any of the Feynman books. I tried to get you to buy *Surely You're Joking Mr. Feynman.*

Anyway, Feynman explained that he had no interest in honors. That resonated with me. That's one thing about working with my old college that has annoyed me. Colleges tend to think almost totally in terms of honors. Phooey.

Sure, I'm a past president of the Peterborough Chamber of Commerce. Big deal. But I am happy that as president I was able to build the membership up by over ten times. And when I was on the local hospital board I helped them save nearly a million dollars. When I was a member of the board of the NH High Tech Council I came up with the program that is now the mainstay of the organization.

Look, if you've got a ham hero around your area who has been accomplishing things, why wait until the guy dies to let the world know what he's done and doing? I don't want honors and titles, but that doesn't mean I wouldn't like to be recognized for some of the things I've done to help inch the world along a little. I'll bet you've got some movers and shakers who would appreciate knowing that their work hasn't been totally unnoticed. So let's see some articles submitted for 73 which will both help thank them (while they are still alive) for their accomplishments, and maybe serve as role models for the rest of us.

Maybe the chap has held an ARRL position. Like an SCM. Fine, but what did he accomplish of some lasting value as a result of that? How specifically has he or is he helping to improve our hobby? Very few hams I can think of who have contributed significantly to our hobby were ever publicly thanked while they were alive.

Gus Browning W4BPD gave tens of thousands of DXers a bunch of new countries. He then entertained hundreds of thousands of us with the wonderful published stories of his adventures. As far as I know Gus never won any honors. No awards. But he contributed enormously to our hobby. I don't remember anyone writing an article about Gus, thus helping us to thank him for what he did for us.

You write the articles and I'll make the space available to help let the hams who are working to make this a better hobby know we appreciate what they're doing and have done. How about an article on Bill Pasternak WA6ITF and his Newsline work? Or Dave Bell W6AQ and his ham promotional films?

Now get your word processor busy and don't forget some good pictures and a disk copy of the text. We've got a bunch of unsung ham heroes who should be sung about before they die.

Are You Illiterate?

My dictionary defines "illiterate" as "lacking education, untaught, and unable to read and write." Since you are reading this, we can eliminate the "unable" part. But that still leaves us with "lacking education." The current term for this is "functionally illiterate." So let me get in your face and ask a rude question. I've been recommending quite a few books in my recent editorials. Okay now, how many of them have you bothered to buy and read? Hmm. I thought so.

Sure, I get a scattering of letters from readers thanking me for putting them onto the books I've recommended, but the other 99% of you have been silent. Which is a blessing, since my mail is already more than I can handle. And some readers wonder why I'm not answering e-mail hourly. Zut, alors!

It's bad enough that our terrible school system has turned most of us into turnips...now they're doing it to our kids and we're too brain-dead in the water to even put up a whimper. And the government, in league with the teacher's unions, is all geared up to turn your grandchildren into turnips too. Lacking creativity, a knowledge base, or even the interest to build one. Did you see the movie "Clueless?" Or "Kids?" Oh, you're waiting for the video version so you can sit and watch it at home, eating chips and drinking a few cold ones, right?

There's a tape I'd like you to send for. It's a lousy $5 (that just helps cover the costs of mailing) and if it doesn't shake you out of your torpor and get you interested in finding out more about what's gone wrong with the American school system (note: I can't honestly call it an educational system), then you deserve to be a dedicated League Life Member.

The tape is by the president of Hillsdale College. That's in Michigan. In it he explains what's gone wrong with our colleges...which are educationally, financially, and spiritually bankrupt. As President George Roche puts it. Hillsdale is the most politically incorrect college in the country. Well, he's an iconoclast. He's been president of the college for 24 years and it's one of the most outstanding colleges in the country. Yes, I know you're a ham and therefore you are cheap, but this one time spring the $5 and find out what's going on. It's a tape I think you'll play over and over in your car. I know I have. Send your $5 to Hillsdale College, Hillsdale MI 49242-1298.

Once I have your attention, I'm hoping to get you to get a copy of Thomas Sowell's *Inside American Education*, Free Press 1993, 368p, ISBN 0-02-930330-3, $25. I hope you've been reading Sowell's columns in *Forbes* and *Conservative Chronicle*. You can find *Forbes* on any newsstand, but the *Chronicle* is by subscription only, at $42 a year; call 800-888-3039. It's weekly and has some good stuff in it, though as you say about my editorials, I sure don't agree with everything conservatives hold dear.

The most important thing you leave behind in this life is your kids. So why aren't they more important to you? Today's parents (a product of our school system) are largely ignoring their kids. They start out by permanently harming their children by smoking and drinking before and during pregnancy. Then they let the hospital put the babies into their nursery instead of staying with the mother. Then comes four years of almost total neglect known as day care, followed by 12 years of our mind-numbing school system (did you read *Dumbing Us Down*, like I asked?). All, including massive parental neglect, at every step of the way. So we end up with exactly what we've nurtured: unmotivated, ignorant, unruly kids. And we wonder why they "go bad." Why they are into drugs and getting pregnant. Gee, big surprise!

Look, we got rid of King George and what used to be Great Britain, but is now Britain, a couple hundred years ago. If we can take our eyes off our TV soaps and sitcoms long enough, we can work together and fix our school system...and all the other niggling problems we've let our government create and nurture for us while we've been too busy enjoying life to pay attention...like drugs, crime, welfare, the deficit, a bureaucracy that's now larger than our manufacturing industry base, our crooked Congress, and so on.

You can start by getting the tape. And then drop me a line telling me how you don't always agree with me. About what?

Just A Coincidence

Have you been keeping up with your reading? There are several good books on chaos theory. Read any of them? How about synchronicity? You know, coincidences.

How about this one, from *Incredible Coincidences* by Alan Vaughan. In 1893 Henry Ziegland, of Honey Grove, Texas, jilted his sweetheart, who then killed herself. Major bummer. Her brother tried to get even by shooting Zieglaud, but the bullet only grazed his head and buried itself in a tree. The brother, thinking he'd killed Ziegland, committed suicide. Guess it ran in the family. In 1913 Ziegand was cutting down the old tree with the bullet in it. It was a tough old tree, so he used some dynamite. The explosion sent the bullet through his head, killing him.

The book is full of such remarkable "coincidences."

Another book, Serendipity... Accidental Discoveries in Science,

LETTERS

From the Ham Shack

Raphael Escoe DDS WA2MMT. Re your editorial on AIDS, the law requires that medical workers wear gloves when working with patients to prevent the spread of AIDS, TB, etc. My electrical tests show that three of five brands of latex gloves leak after 20 minutes of use. All vinyl chloride gloves leak. This presents an opportunity for hams to design and sell a gadget which will sound a buzzer if the gloves leak. One electrode would be hooked to the doctor or nurse, perhaps with a wrist band, and the other to the patient. This would make a great how to build it article and a great little gadget to manufacture. It might also be used to verify condom integrity.

How about it? Will I be seeing some articles on clever alarm designs? . . . Wayne

Mel Mahler WB9MAF. Your December editorial leaves the wrong impression as to the purpose of CTSS and who may use a frequency. Twenty years ago it was evident that when one lived eighty miles from a swamp full of alligators (Chicagoland), something was required to maintain the sanity of control operators. The answer was to require CTSS to activate repeaters. It didn't stop high powered ops in the city from capturing the repeater receiver, but there was no transmission until a local station had access. Over the years most rigs now come with capability built in (if you can find the book to translate the settings) and consensus was reached on a plan (one CTSS tone per area code in Indiana). No reasonable amateur mentality should ever construe that requirement for CTSS equals a "private" repeater. In fact, there is much doubt in my mind that such a thing can or should exist on the amateur bands. Private repeaters sound much more like a commercial service and private frequencies don't even exist there. Those amateurs that don't fit in the above mentality are left to their own groups, usually around repeaters that are so antagonistic as to account for only their presence. I know you write editorials to cause thought, but please start the process from a reasonable point.

Yes, I'm well aware of the legitimate use of CTSS, but when I visit city after city where there are no such extenuating circumstances and find the repeaters almost 100% CTSS restricted, some other explanation is inescapable . . . Wayne

Larry Reitz WA8CWD. Earlier this month I had a problem with my Ramsey FX-146 transceiver. After replacing the T/R switching transistor I found the receiver had gone deaf. After further examination I found the preamp transistor was dead, probably from my having pumped the transmitter output into it. Unable to find a replacement for this transistor I called the Ramsey tech support. To my surprise their receptionist had a replacement sent the same day. Two days later it arrived and I installed it and was back on the air. Not only was I surprised to get such a fast answer, but to receive the part that fast was amazing. The Ramsey staff is really on the ball. Not having to run up a monstrous phone bill running through a dozen touch tone sequences to finally be told to leave a message that no one ever responds to was a pleasant surprise. All ham radio and computer manufacturers should look to them as an example of how to treat customers. You can bet that I'll be buying more Ramsey equipment. Ramsey not only sells high quality kits, but they provide superb support when you need it.

Name and Call Withheld By Request. Wayne, if we could eliminate federal welfare this would help eliminate crime. People would have to go find work. They wouldn't have so much time to get into trouble. Additionally, they might be too tired when they clock out to go out somewhere and start some trouble. They would have more self respect and maybe, just maybe, some of that would be directed to more respect for society at large. It wouldn't work for everyone, of course; no program would be 100% effective. What about those people that really need help? The churches and charitable organizations can step in; some of them already do. I have a tremendous amount of respect for the work the Salvation Army does.

I used to be the editor for the local ham club newsletter. I quit, both being editor and being a club member. I'm 48, and was one of the youngest members. If anybody read the newsletter, I couldn't tell. I put out questionnaires, held contests, asked for volunteers to be technical assistants, tried to set up Saturday workshops to introduce members to packet, satellites, computers, 220 or 440 MHz activity. The end result? Zilch, zero, nada. No one would even submit articles on any item they had bought or constructed, or any interesting QSOs they had experienced. Unfortunately, in talking with members of clubs in other cities, they say the same holds true everywhere: Old white men set in their ways. What can we do? Leadership is the key. Dynamic young(-minded) people need to join the stagnant clubs, and get involved. You don't have to try to get the old-timers interested in something new; just get acquainted. Bring in new members who have an interest in newer ideas, like packet or satellites. You need not push the dead weight aside; just make room for the newbies. I used to write in the newsletter and say out loud at the monthly meeting that there was plenty of room in the club for different interests. There might be more people interested in DX contests than in packet, but you could do both if you wished. It was your choice; participate in any aspect you wish. For a while, with the no-code Techs, we got some fresh blood in the club. We even had enough volunteers to provide communications for a city event. However, there was no encouragement from the older members, so the younger ones lost interest and drifted away. The only school-age members we picked up (two!) were children of adult members. There are a few interesting people in the club, even now, but they don't take an active part. The same people stay in the same offices. Maybe we should have term limits! Well, the city is a retirement community, so most of the people who join the club are retired; when they die off, other retirees take their places.

How do we get in the schools and attract kids? I don't know. Some of us members went to the local schools, public and private, and gave short presentations on amateur radio. The end result? You guessed it: No response; no questions from the audience; no comments. In one instance, they showed up just to get out of history class. The few young people I meet are not interested, especially when they hear the terms "study" or "exam." This leads us back to the fault of public (mis-)education. A kid can do nothing more than sit in a room for 12 years and he knows that he won't be denied a diploma. He never considers landing or keeping a job. This might date me as middle-aged, but it seems most young people are interested in chemical entertainment (drugs or alcohol), sex, and the acquisition of material goods (cars or clothes). So many don't want to work for anything anymore. Perhaps they realize that the main qualification to get a job is to be a member of a "minority" group. Yes, that's a barb. Point made, most employers won't keep an incompetent worker; maybe government or teaching jobs, but not privately owned smaller businesses. Fundamentally, the problems with public education begin with the parents. As they turn more and more responsibility over to others to raise their kids, so the kids become a product of the system. If the parents are interested in their kids and their kids' future, it shows, and the kids are more interesting to be around.

That's enough for now. I will write again sometime. Hopefully, you will read this letter and want me to write again. Keep writing in your column about books that you find interesting; I have been able to find a few of them at the used book store.

Before welfare we didn't have people starving, even in the depths of the Depression. We had soup kitchens and so on. Rather than being a safety net, welfare has become an easy alternative to working. I hope some readers bothered to watch the TV program on welfare, showing two big, fat, lazy Lebanon, NH, women who had no interest in ever working. Now, I can understand why you couldn't get the club members to write. I have about 100,000 ham readers and I can't get many of them to write either. So I can imagine the problems you had with a club of 30-50 . . . Wayne

Arthur Harris KC6WZJ. The other night, suffering with insomnia, I turned on the radio and very luckily caught the beginning of your conversation with Art Bell. I listened to the whole three hours of your complete talk. Very enlightening to say the least. I heard what I never thought I would ever hear...a keypounder saying that code was anything less than God's gift to mankind. Boy, you must really catch a lot of flak for that heretical point of view. The boys down at ARRL and all the other keynuts must be demanding that your license be permanently revoked. I am subscribing precisely because of that view. As an older ham, but young as a licensee, I really resent the fact that as a no-code Tech I have such restricted band availabilty. I got my license soon after the no-code became available. I especially resent that individuals with higher class licenses have such doubtful technical competance. Recently at a ham meeting during a conversation I referred to three-phase power. Another ham (with HF privileges I don't have) asked what three-phase power was. He not only didn't know what three-phase power was, he didn't know what single-phase power was either! Boy, it's a good thing I didn't bring up wye and delta three-phase.

I feel that the difference between CB and amateur radio is technical ability and radio discipline. Basically, code is obselete. The code requirement is analogous to requiring the 1st Cavalry Division to wear riding pants and high boots and ride horses every day. Some people enjoy riding horses and some people enjoy code. This is their right, but to force it on others is not.

Art obviously has never read 73 or he'd never call me a keypounder. Computer keys, sure. Teletype keys, absolutely. But instead of no-coders griping about the code barrier I wish they'd either shut up, buy my $7.95 blitz course in learning the 13 wpm code the easiest way known to man (or even woman), or start doing something to get the ARRL to recognize that the day of radio relaying by Morse code may soon be over . . . Wayne

QRX . . .

Fight Winter Blues

If your DX life has been in the dumps due to the solar lull and winter conditions you might find the following bulletin of interest. It was pulled from rec.radio.amateur.misc, one of the Internet news groups dealing with amateur radio. If you point your web browser at the URL (universal resource locator or web address) http://solar.uleth.ca/solar you will find yourself at an almost real time propagation forecast site. The available information can be used for everything from aiming your beam for that great circle route to deciding if you should just stay in bed, read the latest issue of *73* and wait for conditions to improve.

New WWW Radio Propagation and Ionospheric Services Are Now Available

http://solar.uleth.ca/solar

Our main homepage has been supplemented with several new ionospheric services that should be of wide interest to radio communicators (amateur and professional).

Every hour, approximately 15 to 20 minutes past each hour, our system regenerates five real-time globally contoured maps of various important and useful quantities:

1. Global Maximum Usable Frequency Maps. (http://solar.uleth.ca/solar/www/realtime.html)

2. Global Maps of the F2-Layer Critical (Penetration) Frequency. (http://solar.uleth.ca/solar/www/fof2.html)

3. Global Maps of the E-Layer Critical (Penetration) Frequency (foE). (http://solar.uleth.ca/solar/www/foe.html)

4. Global Maps showing the Height Maximum of the F2 Layer (or the altitude above the surface of the Earth where the ionospheric electron density is highest). Information regarding the likelihood of non-great-circle propagation can also be determined. (http://solar.uleth.ca/solar/www/hmf2.html)

5. Global Maps of Solar Zenith Angles, or the distance of the Sun away from the zenith (the point in the sky that is exactly overhead). Shows the elevation angle of the Sun above or below the horizon for any location on the Earth. (http://solar.uleth.ca/solar/www/zenith.html)

Each map includes the plotted solar terminator (sunrise/sunset line), the gray-line corridor where the Sun is up to 12-degrees below the horizon, the location where the Sun is directly overhead, and the locations of the auroral ovals based on the latest 24-hour planetary A-index (updated every 3 hours).

To our knowledge, these services form one of the most extensive set of near-real-time maps pertinent to radio propagation and radio navigation on the Internet.

FAR Scholarships Available

The Foundation for Amateur Radio, Inc. plans to administer 57 scholarships for the academic year 1996-1997 to assist licensed radio amateurs. The Foundation, comprising more than 75 local area amateur radio clubs, fully funds eight of these scholarships with the income from grants and its annual hamfest. The remaining 49 are administered by the Foundation without cost to the various donors.

Licensed radio amateurs may compete for these awards if they plan to pursue a full-time course of studies beyond high school and are enrolled in or have been accepted for enrollment at an accredited university, college or technical school. The awards range from $500 to $2,000 with preference given in some cases to the pursuit of certain study programs or to residents of specified geographical areas such as Delaware, Florida, Maine, Maryland, New Jersey, Ohio, Pennsylvania, Virginia and Wisconsin. Amateur radio clubs are encouraged to announce these opportunities.

The Foundation for Amateur Radio, incorporated in the District of Columbia, is an exempt organization under Section 501 (C)(3) of the Internal Revenue Code of 1954. It is devoted exclusively to promoting the interests of amateur radio and those scientific, literary and educational pursuits that advance the purposes of the amateur radio service.

Information and application forms may be requested prior to April 30, 1996 from: FAR Scholarships, 6903 Rhode Island Avenue, College Park MD 20740.

Hams In The Snow

In typical fashion, the amateur radio community mobilized and provided coordination and emergency communications for the blizzard that hit the east coast in early January. In places like Montgomery County, Maryland and Suffolk County, New York hams in four wheel drive vehicles helped out area hospitals, provided coordination of food and supplies for the sick and elderly and did the things that amateur radio operators do every time an emergency comes up.

So... what's so special? What's the big deal? Nothing except that with all the intense media coverage no one took the time to tell the story to the public. Based on a sampling of hams talking about this no-press phenomenon, feelings are mixed. Many hams think its part of the package - if you have a license you should be there to help by using your skills, equipment, training and time. This, indeed, is the true spirit of amateur radio and should be commended. But there are a good number of operators who feel a little publicity wouldn't hurt when antenna restriction time or band allotment discussions come around. The answer as to what to do is best explained by a ham who posted on an internet discussion group. "Do the best you can to help your community in an emergency but also keep your local and state media outlets aware of Who's doing What, Where, When and How. Names, addresses, telephone numbers! Make it easy for the media to tell a positive human interest story and they will!"

Never Say Die

Continued from page 4

by Royston Roberts, John Wiley, 1989, $13, 270p, ISBN 0-471-60203-5, has a bunch more "coincidences." Like the way Daguerre invented the Daguerreotype, the first practical photographs. He'd been able to make faint photos on silver-coated copper plates, but they weren't bright enough to be seen easily. He tried every way he could think of to intensify the image. Then, one day, he put an exposed plate in a cupboard which had some chemicals in it, planning to clean the faint image off and reuse the plate. When he took it out a few days later he found the image had been intensified!

So he tried each of the chemicals in the cupboard, but none worked. He then looked closer and found some drops of mercury which had come from a broken thermometer. And that's how the Daguerrotype was invented. Unfortunately, mercury is very poisonous, so many early photographers died of mercury poison. These days we're still making people sick and killing them with mercury, courtesy of your local dentist, who is still using it in your amalgam fillings. Well, at least it's a slow poison.

I remember running an article in *73* many years ago about the almost discovery of the transistor. A couple hams had run into the semiconductor phenomenon while experimenting, but the importance of it had escaped them. You have to have curiosity and be open to new paradigms. Velcro was invented by a chap who wondered why cockleburs stuck to his clothes so tenaciously.

Serendipity can give you the hints, but it's up to you to turn this into inspiration. Take off your blinders! Whatever it is that causes these coincidences is still at it and will work for you, if you'll only let it. Or maybe you honestly believe that every single one of the tens of thousands of sincere stories about angels helping people are bogus.

Ancient History

First, I'd like to tell you about the time I called an admiral a traitor, and then, to how this led me to get the inside scoop on ARRL General Manager Budlong, W1BUD.

This all started when I was the editor of *CQ*, one of the ham magazines. I'd been summoned to the Pentagon for a briefing. Briefing? It was anything but brief. An Air Force colonel obfuscated for over an hour, speaking Air Force jargon, which I translated as best I could into English. It had to do with the Air Force needing to take over our 450 MHz band for a new radar project.

When he got through, I asked if what I'd heard translated into the Air Force, faced with the problem of the Russians using radar jamming equipment in their bombers, was being countered by our setting up so many radar systems that even a fleet of bombers couldn't jam them all? To make room for this mass of radar systems we hams would have to give up our 450 MHz band to make

JY74X-JY74Z: A Joint Jordanian-Israeli Operation

One peace process dividend: DXpeditions to Amman and Mt. Nebo, celebrating the first anniversary of the "Washington Declaration" peace accords.

Joe Obstfeld 4X6KJ-JY8KJ
PO Box 873
Kiryat Ono 55000 Israel

The preliminary arrangements had been going on for a very short period of time. Everything was set and the final word would be coming from the Royal Palace in Amman, depending on His Majesty's schedule. Word of the proposed date was transmitted by fax to Amir 4X6TT, and he made all the calls and arrangements.

On Wednesday evening I received a call, just stating that I was requested to join this operation, and that the team was leaving on Monday the 24th of July. I asked just a few questions: Who is going? Where do we stay? What about a visa for Jordan? What about transportation? etc. The answer was simple: "It's all been taken care of, just come."

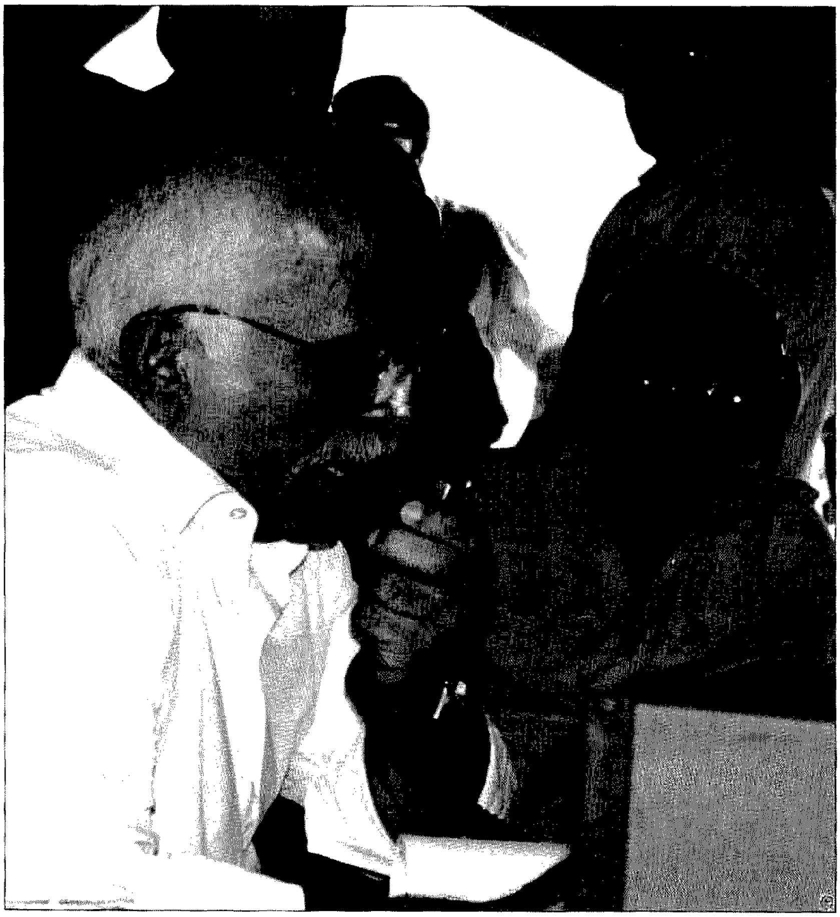

Photo A. King Hussein JY1 operating JY74Z on Mt. Nebo.

I was doubtful and couldn't believe it until I phoned the Secretary of the Jordanian Amateur Radio Club, Mohammed JY4MB, with whom I've been in regular contact. We'd met many times at international conferences and had spent many hours planning and discussing joint cooperation between our two societies.

"What resulted was monstrous; it unleashed a free-for-all."

He was pleased to tell me, "I'll see you in a few days here in Amman." He confirmed the entire plan, saying, "What are you worried about? Everything is taken care of, just make sure that at 10 a.m. on Monday you're at Allenby crossing. Salaam, Shalom, see you on Monday!"

After checking my passport's validity, I dug up a small suitcase, prepared film and batteries for the picture and video cameras, and I was ready to go.

JY74X Amman

At precisely 7 a.m. the rented minivan limousine passed through the heavy early morning Tel-Aviv area traffic and continued on to Jericho in the Jordan Valley. The van was loaded to the brim with equipment for the mission, as well

as with the operators Ami 4X4DK, Amir 4X6TT. Moni 4X6ZK. Dov 4Z4DX. Eyal 4X6RE and me. All of us were fascinated with the speed and efficiency of the preliminary arrangements for this DXpedition. During the two hour trip to the border. the team was discussing in anticipation what might be awaiting us.

At the Allenby bridge, the Jordan-Israel border crossing, everyone involved did his utmost to make our passage as fast and easy as possible. No wonder! The border officials had received advance notice of our program and the intended operation by none other than the Royal Court in Amman, as we later found out. It was the first time ever that Israeli radio amateurs would be crossing the border to operate with Jordanian amateurs in their country.

"It was the first time ever that Israeli radio amateurs would be crossing the border to operate with Jordanian amateurs in their country."

Within 30 minutes of our arrival at the border the gate was opened and our minivan was allowed to bring our equipment to the other side. It was quickly transferred to one of the Jordanian vehicles that was awaiting us. After greeting Mohammed JY4MB. who came specially to welcome us, and be our escort, we made our way in a convoy of Royal Palace cars to Amman, the capital of the Hashemite Kingdom of Jordan.

First we checked into our hotel, put our personal belongings there, and after a quick lunch we made our way to the clubhouse of the Royal Jordanian Amateur Radio Society. We unpacked the equipment from the van and started to set up the different stations. Within an hour of our arrival, the first station, JY74X, was on the air. We were joined by our Jordanian friends, and as the day progressed more transceivers were pressed into service on different bands and modes.

JY74Z Mount Nebo

Three members of the group went with an escort to Mount Nebo, about 60 km. southwest of Amman, to check out the site and to start setting up so that on the 25th of July operation JY74Z from this site could begin. It was especially important to get on the air on this day, as the whole mission was dedicated to the first anniversary of the Washington Declaration, which was signed at the White House. One year after signing the Principles of Peace between Jordan and Israel, radio amateurs of both countries got together to put this DXpedition on the air and handle the pileups.

Early in the morning on Tuesday, July 25th, the entire team assembled in the hotel lobby and our awaiting Royal car and escort took us to Mount Nebo, elevation about 800 meters above sea level, an hour's drive from Amman. As soon as we arrived we began operating. One by one the transmitters fired up on the air on SSB and CW. Frequently we had to change operators, because of the terrible 40° Celsius (104° Fahrenheit) heat that prevailed at the time in our tents. The pileups were ear-shattering. After supper, provided by the Marriott Hotel Catering Service and brought to the mountain site, the team split into two groups. One stayed overnight on Mount Nebo, in the seemingly freezing cold. Temperatures in the desert change dramatically to extremes during day and night. The other group went down to the city, to operate from the clubhouse in Amman.

JY1 Incites Bedlam

The next day the program was the same as the day before, but the heat was worse. The highlight of the day was the appearance of none other than His Majesty King Hussein JY1 on the air on both HF and VHF. The excitement and enthusiasm increased as everyone of the team present had a chance to have a QSO with His Highness from his Palace in Amman. Afterwards the pileups doubled, the frenzy on the HFs went out of control and His Majesty decided to QRT and maybe appear later and try again.

Around 5 p.m. we were honored as His Majesty arrived in person at the Mount Nebo site. After introducing ourselves, he went on the air: "This is JY74Z. JY1 at the microphone." A few QSOs were made, but it was almost impossible to pick out a callsign through the roar of the pileup. The word most used during that half hour or so was "stand by, stand by." Amateurs around the globe just did not listen, each one thinking that he will make it through. But only those who have been on the other end of a pileup know that the colossal noise created at such moments gives cause for the big switch being pulled. His Majesty put down the microphone and signed the log. For a few lucky ones this will be the most unforgettable and special QSO ever. Meanwhile refreshments were being served, and a lively, pleasant eyeball QSO ensued.

The Final Day—Almost

Thursday July 27th was supposed to be the final day. During the morning hours our driver took all of us on a sightseeing tour of the city, after which we returned to The Mountain and continued working the pileups. As the day progressed it became clear to us that it could not be the final day of operation, as on Friday the Jordanian part of the border is closed and on Saturday the Israeli side is shut down. At various times during the day His Majesty JY1 came on the HF frequency and the frenzy on the bands continued. During the night it was the same. As word spread that there would be a special QSL card for this occasion, the amateur radio world tried to work the two stations on every band and mode possible.

Friday July 28th, in the morning, we were summoned to the residence of His Highness Raad Bin Zeid JY2RZ, the Chairman of the Royal Jordanian Amateur Radio Society, to receive officially and personally our Jordanian operating licenses. At the end of this eyeball QSO it was decided to go back to work. His Highness JY2RZ would come on frequency and take some calls. Enthusiastically we went back to The Mountain and tried to regulate the pileup as the two most wanted Jordanian callsigns came on the air simultaneously.

What resulted that afternoon was monstrous: it unleashed a free-for-all on the HF bands, uncontrollable even by the best of operators. "Stand by, staaaaand by, quiet!" But nobody listened and the roar continued. The few very lucky ones who "made the contact" must still have adrenaline running through their veins.

At sunset, we took time out for a most elaborate barbecue, prepared for us by

the Marriott Catering Service, with a most unforgettable view as background. From Mount Nebo one can oversee the Jordan Valley, the Dead Sea on one side, Jericho and the river Jordan on the other. As the sun set, the colors of the landscape below and on the horizon were exquisite. Here on this spot Moses went to the top of Mount Nebo and The Lord said to him, "This is the land which I swore to Abraham, Isaac, and Jacob that I would give to their descendants" (Deuteronomy). Later that evening, the pileups reverted to the normal state that we had gotten used to during the days and nights before.

The Final Day—Really

Saturday July 29th, really the last day of this very special operation, we decided that later in the afternoon the stations would be dismantled and antennas taken down. The multitude of equipment that we brought had to be packed and made ready for the return trip. At approximately midday, once more the frenzy peaked, as one more time His Majesty JY1 came on the band from his Palace QTH in the southern city of Aqaba. Unfortunately, the HF propagation was very bad, and very few had a chance for a contact. We at Mount Nebo could not hear him, so the net control was done somewhere in Europe. We left Mount Nebo, had one more look at the unbelievable view of the surrounding landscape and went downhill with all the equipment that had accumulated at the site over the past days.

We made more than 15,000 QSOs on all the bands except 160 meters. Repeatedly we gave our QSL info, so here it is one more time: All QSLs go via JY6ZZ, direct or bureau.

We arrived at the hotel in the afternoon. Tired and dusty, we rested a bit, took a well-deserved shower, and prepared ourselves for the festive dinner that we were invited to by His Highness Prince Raad JY2RZ. At the appointed time we all assembled at his home, where our fellow Jordanian amateurs, who had been with us all the time, joined us. We discussed the pileups, the activity of the past days and the plans for the future.

We were taken completely by surprise when His Majesty King Hussein JY1 arrived and joined us for the evening dinner. Many anecdotes were told and pictures taken. For us six Israeli hams, it was the ultimate climax of an incredibly successful and special DXpedition. We hope that we will have many more opportunities to work together with our fellow hams from JY-land.

On Sunday July 30th we packed the equipment, cleaned up the mess, gathered and signed the logbooks, got our few personal belongings from the hotel, returned the keys and everything was ready for the return trip. Shaking hands and saying good-bye was certainly not easy after such a week.

Photo B. Mohammed JY4MB at JY74Z. The fan? It's 104° F!

Sigh, Back To Reality

Within a few hours we were back in the bustling Tel Aviv traffic. Everything seemed like a dream—a dream that had come true.

Allow me a word of thanks to Amir 4X6TT, who coordinated the whole event, and to the wonderful team of Israeli operators for making this such a memorable week. Special thanks to the JY operators, friends, our partners in the task of controlling the pileups. It was great being together with you for this momentous and historical performance. Mohammed JY4MB, Secretary of RJARS, did an amazing job of orchestrating, guiding, and supporting the whole operation, from the beginning until the end. Special thanks for his endurance in staying with us the whole time. And thanks to Ibrahim JY5EV, for the endless technical support, for keeping the towers and antennas up and the amplifiers running.

Thanks too to Ali Shoukri JY3AK of the Royal Palace, for the intermediary, logistics and support. There are no words to describe the appreciation and gratitude from all of us to His Majesty, King Hussein of Jordan, JY1, for all you have done for us. Without your personal involvement and assistance this event could not have come to pass. Salaam—Shalom.

Editorial Note

Having operated from Amman as JY1 and JY8AA, it was particularly enjoyable for me to get this report of the joint JY/4X team at Amman and Mt. Nebo. I've been to Mt. Nebo and looked out over the biblical area. If you can, plan on a visit to Jordan, where you'll have no problem getting a JY8 call. And plan to see this small country from Irbid in the north to Aqaba in the south. You'll bring back wonderful pictures of the ruins at Jarash, the pink city cut out of the mountains at Petra, the view from Mt. Nebo, the crusader's fortresses, and the tiled floors of churches at Madaba going back to the Roman and Greek times. Heck, you may even be able to organize a visit with His Majesty! . . . Wayne.

Into Orbit with the Final Phase 3 OSCAR

It's a bird! It's a plane! It's...

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

The Amateur Satellite Program has come a long way since the launch of OSCAR-1 on December 12, 1961. OSCAR stands for Orbiting Satellite Carrying Amateur Radio. OSCAR-1 was built by Project OSCAR, a West Coast group. The launch took place only four years after that of Sputnik-1 from the Soviet Union. OSCAR-1, weighing in at 10 pounds and costing about $64, carried a 140 milliwatt CW beacon transmitting "HI" on 145 MHz. The transmissions lasted 22 days till the satellite re-entered the atmosphere from its very low earth orbit.

Since then there have been many amateur satellites, some simple, and others supporting many complex experiments and transponders. We have had satellites with simple telemetry beacons, with voice and CW transponders like repeaters in the sky, and with complex, digital store-and-forward flying BBSs, or radio bulletin-board systems.

Phase 3-D is the largest, most complex and international "hamsat" project to date. It is scheduled for launch from French Guiana later this year on board an Ariane-5 booster. The main body is nearly seven feet in diameter and three and a half feet tall. With solar panels extended, the wingspan is over 20 feet. The satellite weighs in around 500 pounds with an estimated program cost of 4.5 million dollars. When Phase 3-D achieves orbit it will be given an OSCAR number, perhaps AMSAT-OSCAR-29, or something in the low 30s, depending on the schedules of other projects waiting for launch in 1996.

Support for this immense program comes from AMSAT groups around the world. No one ham organization has the resources to plan, build and get a ride to orbit for a satellite of this magnitude.

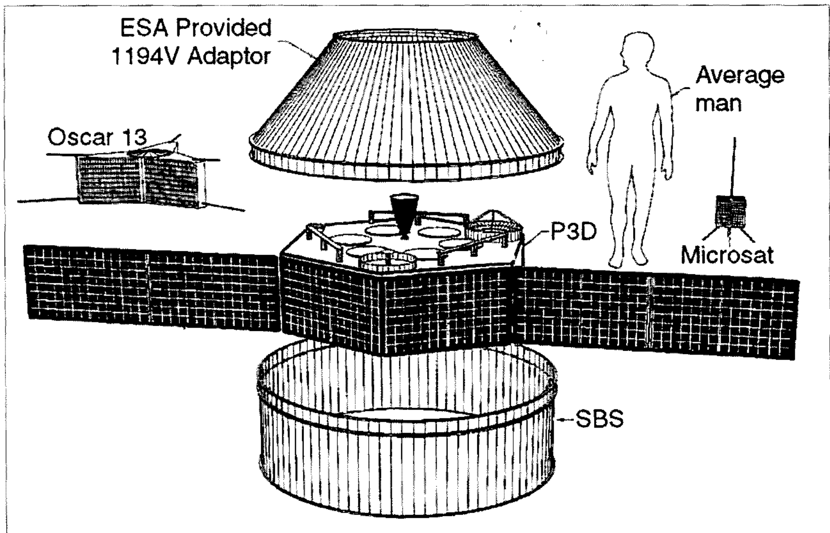

Fig. 1. The Phase 3D spacecraft.

What is AMSAT?

AMSAT stands for Radio Amateur Satellite Corporation. The original AMSAT was founded in 1969 in the District of Columbia as a non-profit educational organization dedicated to foster amateur radio's participation in space research and communication. The first project for the new corporation was getting a launch for Australis-OSCAR-5 in 1970. This was to be the last Phase 1-type satellite, i.e. low-earth-orbit and short life.

"OSCAR-1 weighed 10 pounds and cost about $64. Phase 3-D weighs around 500 pounds and the estimated cost is $4,500,000."

The second project for AMSAT was the first Phase 2-type satellite, AMSAT-OSCAR-6. The Phase-2 classification requires that the hamsat be designed for long life. A-O-6 was expected to last a year with solar cells and rechargeable batteries. It lasted over four years till the batteries shorted out. Today we have OSCAR satellites built by many groups around the world and the "numbers" are increasing rapidly. There have also been several RS satellites from the previous Soviet Union. With many groups using the AMSAT name, like AMSAT-DL of Germany and AMSAT-SA of South Africa, the original group in the United States is now called AMSAT-NA for AMSAT North America. Funding for Phase 3-D comes from membership dues, individual and

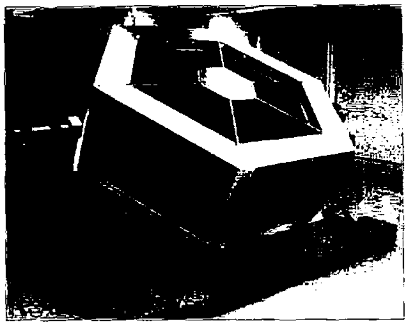

Photo A. The Flight Model Phase 3-D Spaceframe inside the clean room facility. The specially built handling structure will allow easy access to all parts of the satellite during integration.

corporate donations. The American Radio Relay League has been instrumental in financial support of the 1.5 million dollars (cash, labor and components) pledged by AMSAT-NA.

AMSAT-NA provides a vast array of services to support those interested in learning about amateur-radio satellites. To help track each satellite, the AMSAT Software Exchange makes tracking software available for most popular personal computers. AMSAT also runs its own QSL bureau and awards program for satellite users.

The AMSAT-NA Field Organization is ready to help those looking for information on a more personal level. With over 100 Area Coordinators, there are some in most localities willing to answer questions about the satellites, arrange for demonstrations or provide talks for local clubs and ham conventions.

AMSAT-NA sponsors regular HF nets with the latest news on satellite activity and Phase 3-D progress. One of the most popular nets is held every Sunday at 1900 UTC on 14.282 MHz USB. In addition there are many VHF nets around the country with similar information coverage with supplementary local items of interest. One local net, the Houston AMSAT Net, can be heard across most of North America at 10 p.m. Central Time via Anik E2, Transponder 18, 5.8 MHz audio subcarrier. It is also carried by various VHF and UHF repeaters in addition to a 160-meter feed on 1860 kHz AM from WAØRCR in Missouri.

Current AMSAT information is also available via the Internet. A World Wide Web page can be found at *http://www.amsat.org*. There is also a 'ftp' site at *ftp.amsat.org*, and up-to-date discussions about Phase 3-D and other topics can be checked out by subscribing to *amsat-bb@amsat.org*. Just send a message to *listserv@amsat.org* to subscribe. More information about AMSAT, telephone BBSs and nets can be obtained for a self-addressed stamped envelope to AMSAT, 850 Sligo Ave., #600, Silver Spring MD 20910.

Why Phase 3-D?

With so many amateur-radio satellites in the sky, why build such a large and expensive one? The current satellites have limitations that Phase 3-D is designed to answer. The Phase-3 series of amateur-radio satellites are designed for long-life and wide, simultaneous, geographical coverage. They are built to last several years and have high orbits.

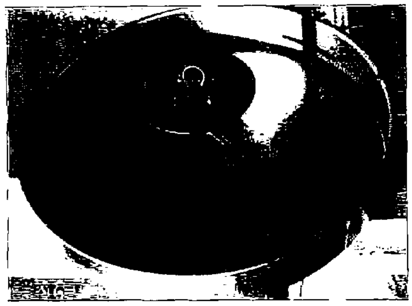

Photo B. The completed Phase 3-D flight model L-band antenna undergoing gain and pattern testing at the integration facility's antenna test range. Preliminary gain measurements exceeded 15 Dbic with a surprisingly clean pattern.

"Every day large volumes of E-mail, pictures, voice files, programs, bulletins and telemetry are sent via low-earth-orbit digital satellites. Phase 3-D will also provide connections between ground-based computers and remote users in real time."

The current Phase-3 satellites include AMSAT-OSCAR-10 and AMSAT-OSCAR-13. A-O-10 was launched in 1983. Although the on- board computer is no longer working due to radiation damage in the memory system, the UHF to VHF linear transponder is still operational when the solar cells are receiving enough sunlight to power the radio gear. A-O-13 went into orbit in 1988. Although most of the systems still work well, the satellite's orbit will decay in December of this year due to orbit instability caused by gravitational effects of the moon and sun. Phase 3-D is designed as a replacement for A-O-10 and A-O-13, with some significant extras.

A-O-10 and A-O-13 provide excellent coverage with their high elliptical orbits, but the orbital characteristics of both require significant tracking programs to predict future access from a specific point on the earth. The apogee or high point of their orbits also fluctuate over time from Northern Hemisphere to Southern Hemisphere coverage, and back again. The final orbit of Phase 3-D will not fluctuate over time, but will maintain stability and provide a repeating pattern that will allow users to predict where the satellite will be on any given day and time.

The orbit modifications that will be performed on Phase 3-D after launch is a two-year process to go from the original transfer orbit provided by the Ariane launcher to the final stable orbit. After launch the satellite will have a perigee, or low point, of only 200 kilometers with an inclination with respect to the equator of 10 degrees. The satellite's main motor will raise the perigee by 300 kilometers and the apogee by 8,000 kilometers. The long-duration ammonia arcjet motor will provide a very low-energy thrust to bring both the perigee height up to 4000 kilometers and adjust the inclination to 63.4 degrees. This inclination is stable and will not drift over time for the desired elliptical orbit. The satellite will provide optimum performance for users in the Northern Hemisphere.

A-O-10 and A-O-13 provide good signals for earth stations, but only when high-gain antennas are in use on the ground side. A primary goal of Phase 3-D is to improve link margins by 10 to 15 dB on all bands. This means that earth stations will need less power and lower-gain antennas for reliable communication. During periods when the satellite's antennas are pointed directly at the earth, effective communications may even be possible with only omnidirectional antennas, like those on a car.

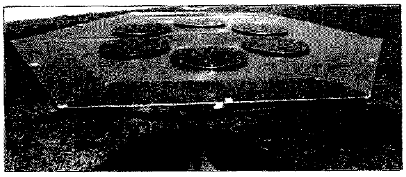

Photo C. The flight prototype U-band patch array undergoes testing on the Phase 3-D integration facility antenna range. The array exhibits measured gain figures comparable to that of a commercial 40-element crossed yagi. Actual on-the-air contacts, with surprisingly good results, have been made through the AMSAT OSCAR-13 satellite using this array as an uplink antenna.

The low-earth-orbit digital satellites have shown the advantages and usefulness of computer-oriented bulletin-board systems in the sky. Every day large volumes of E-mail, pictures, voice files, programs, bulletins and telemetry are sent via these satellites. The opportunities have allowed a glimpse of what can be accomplished with orbiting "digisats," but data rates are still limited and the orbits are low, providing short access periods. Phase 3-D will offer several digital experiments, some at data rates that could support digital video, and access times that will be more akin to on-demand connectivity. Rather than acting only as a stand-alone flying computer BBS, Phase 3-D will also provide connections between ground-based computers and remote users in real time. Connecting to or through Phase 3-D via the Internet is a real possibility depending on the use of ground-based control stations.

Another limitation of A-O-10 and A-O-13 is the effect of high- power earth stations "hogging" the transponder. During normal operation, ground-based users share the transponder output power.

Photo D. "Lights! Camera!" AMSAT-NExecutive Vice President Keith Baker KB1SF gives Dave Brody, Segment Producer of the Sci-Fi Network program Inside Space, *an on-camera tour of the Phase 3-D Integration Facility in Orlando, Florida. The program is slated to appear in late spring 1996.*

Each uplink to the satellite's receiver is re-sent by the downlink transmitter, much like a typical VHF-FM repeater, but with a much wider bandwidth. A linear transponder can handle many stations simultaneously by transponding a range of uplink frequencies to a corresponding range in the downlink. When one station transmits excessive uplink power, the weaker users are "desensed," or just seem to disappear. Phase 3-D has a system called LEILA, a German acronym describing an "alligator" sniffer. An over-powered uplink will be isolated and notified by a series of beeps on the downlink to lower the power level. If the situation is not corrected by the ground user, LEILA will apply attenuation to the signal to even the load on the transmitter. Several levels of attenuation can be applied.

Getting Ready for Phase 3-D

Another goal of the Phase 3-D program is to retain enough commonality with existing hamsats so that current user equipment is not made obsolete. Many popular frequencies in the VHF and UHF bands will be used by the new satellite. A station that is set up to operate via A-O-13 Mode "B" (70 cm up and 2 meters down) will find the new satellite an easy transition. For those looking for new bands and higher frequencies, Phase 3-D offers a promising array of frequencies.

The radio system of Phase 3-D is set up as a matrix of receivers and transmitters. Uplinks and downlinks cover the satellite bands from 15 meters up through 24 GHz. Today's Mode "B" becomes Mode "UV." This stands for UHF (70 cm) uplink and VHF (2 meter) downlink. Typical voice and CW communications will be possible via most of the band combinations. Mode "LS" (1.2 GHz up and 2.4 GHz down) may become one of the most popular by the year 2000.

The anticipated lifetime of Phase 3-D is 15 years. It is truly designed for advanced communications into the next century. To prepare for the new satellite, potential users should begin with today's hamsats. Books and other publications are available from AMSAT and the American Radio Relay League. Start with the easy satellites, like RS-10, RS-12 and A-O-27. Then progress to the high-orbit "DX" hamsats, A-O-10 and A-O-13. A

Photo E. A close-up view of Phase 3-D's flight model Propellant Flow Assembly (PFA). Valves and piping on the left side of the unit will be used to fuel the spacecraft's hypergolic propellant tanks on the ground prior to launch, as well as controlling the flow of propellants to P3-D's 400 Newton kick motor while in orbit. Likewise, valves and piping located on the right side of the PFA will be used to fill the spacecraft's ammonia tanks, and later will control the flow of ammonia to the satellite's arc-jet positioning motor.

series of entry- level articles are in the works for *73's* "Hamsats" column throughout 1996. Start now to get ready for amateur radio's next great adventure.

What's New In Kits?

Take a gander at some goodies.

Robert S. Capon WA3ULH
322 Burlage Circle
Chapel Hill NC 27514

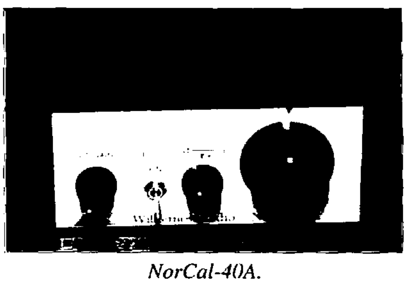
Kit enthusiasts have been rewarded this year with some new kits with great features, and they start at about $100, so there's never been a better time to discover the joy of building your own radio. Your knowledge of amateur radio will be greatly enhanced, and you may discover that one QSO made on your home-brew rig is more satisfying than 10 QSOs made on a commercial transceiver.

This article will provide you with a road map to the latest kits, along with tips and answers to the frequently asked questions for the first time kit builder.

Six Terrific Kits

This article takes a look at six kits: five hot new transceivers and a rather unusual memory keyer (see the full review of the **KC1** in this issue) with a built-in frequency counter. Each transceiver kit features a superhet receiver, and was selected because of its unique characteristics.

NorCal-40A, by Wilderness Radio. The NorCal-40, originally introduced by the Northern California QRP Club, has been reintroduced by Wilderness Radio, a newly formed kit company. The NorCal-40A is ideal for beginners; the jacks and switches mount directly to the board, so there is no point-to-point wiring. This feature makes the radio very easy to build (I put my NorCal-40A together in just two evenings). Wilderness Radio's NorCal-40A comes in a tiny 4 x 4 x 2 enclosure (weighing less than one pound) with a very snazzy two-tone blue paint job. The kit comes with a punched and silk-screened latched enclosure, jacks and knob set, and a first class silk-screened printed circuit board.



NorCal-40A.

"There's never been a better time to discover the joy of building your own radio!"

This 40 meter superhet CW transceiver, designed by Wayne Burdick N6KR, has been optimized for extremely low current drain of only 15 mA on "receive" using headphones. The radio features RIT, AGC, 400 Hz CW filter, and full QSK and delivers 3 watts output. The receiver is absolutely superb. The most challenging aspect of the NorCal-40A is that the builder is required to wind the toroids. First-time builders, however, should not be overly intimidated by this because the radio is supported with excellent documentation.

Sierra, by Wilderness Radio. Again, the Sierra, originally designed by N6KR and introduced by the Northern California QRP Club has been reintroduced by Wilderness. Despite its tremendous sophistication, the Sierra also has characteristics that make it an excellent kit for intermediate builders. Like the NorCal-40A, the jacks and switches mount directly to the board, so there is no point-to-point wiring.

The Sierra is ultra portable, measuring only 5.5 x 6.5 x 2.5 inches (weighing less than two pounds), and has extremely low current drain of 35 mA using headphones. This combination of factors makes the Sierra great for portable and backpacking use, and ideal for battery operation and Field Day.

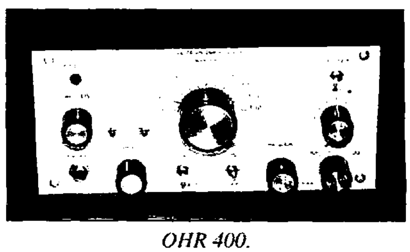
The Sierra can be purchased with up to nine interchangeable band modules for operation on 10-160 meters. The band modules are gold-plated internal plug-in modules. Unfortunately, each band module has eight toroids, so if you intend to build the Sierra for operation on nine bands (like I have), be prepared to wind a lot of toroids. But aligning each band module is a snap, requiring about 15 minutes each to tune up against your main station transceiver.

The Sierra features RIT, AGC, 400 Hz CW filter, and full QSK, and delivers 2 to 3 watts output on all bands. The kit comes with a punched and screened latched enclosure, jacks and knob set, and silk-screened printed circuit board.

OHR-400, by Oak Hills Research. The OHR-400 is a new kit for intermediate to advanced builders. The radio has become my favorite base station QRP transceiver, because it is switch-selectable for operation on 80, 40, 30 and 20 meters, so band changing is effortless.

The OHR-400 also has a superb receiver with silky smooth QSK. The radio really excels at copying very light signals, and it compares favorably with my commercial HF transceiver at digging out stations at the noise level. This makes the radio ideal for milliwatting work. But the OHR-400 is not ideal for backpacking; it has a hefty cabinet measuring 8 x 8 x 4 inches (weighing almost four pounds), and the radio draws approximately 300 mA on receive.

The OHR-400 comes with excellent documentation, and was a pleasure for



OHR 400.

me to build. I really took my time with the radio, and savored the experience of building the kit. The radio has three printed circuit boards that mount on a solid internal aluminum chassis. The boards are the oscillator, receiver, and transmitter. Interconnecting the boards and panel components is accomplished with approximately 50 point-to-point color-coded wires. Again, the documentation for performing the wiring is first class, but this amount of wiring should typically not be attempted by first-time builders. (Oak Hills has other kits ideal for the beginner, like the single band Explorer described below.)

The OHR-400 features RIT, AGC, narrow CW filter, and full QSK, and delivers 5 to 8 watts output on all bands. The kit comes with a punched and screened enclosure, jacks and knob set, and the three printed circuit boards are silk-screened. It has nice finishing touches, including a phono jack on the back with VFO output for hooking up a frequency counter, a rear panel power level pot, an LED lamp, and a knob set and silk-screening on the front panel for an optional keyer. The toroids are pre-wound, clipped and tinned.

Cascade, by NorCal. SSB on 20 and 80 meters. The Cascade is the latest club project by the famous Northern California QRP Club, and was designed by John Liebenrood K7RO. The Cascade joins an elite group of SSB QRP kits, so now phone enthusiasts can discover the fun of building their own SSB transceiver. Despite its similarities to the Sierra in physical design (jacks and switches mount directly to the board, so there is no point-to-point wiring) the Cascade is a kit for advanced builders, and an oscilloscope is very helpful during the test and alignment process.

The Cascade is ultra-portable, with physical dimensions identical to the Sierra, and has extremely low current drain of 80 mA using headphones. So the Cascade is also superb for portable and backpacking use, and ideal for battery operation and Field Day.

The Cascade comes standard with two interchangeable band modules for operation on 20 and 75 meters. The band modules are gold-plated internal plug-in

modules. Each band module has only six toroids.

The Cascade features AGC and speech synthesizer, and delivers approximately 8-10 watts output on each band. The kit comes with a punched and screened latched enclosure, jacks and knob set. and silk-screened printed circuit board. The Cascade's documentation takes the builder through 10 independent stages so that you can trouble-shoot and align the kit as you go.

TAC-1, by S&S Engineering. Synthesized CW transceiver with digital display for 80 or 40 meters. The TAC-1 is the latest in a worthy product line of synthesized transceivers offered by S&S Engineering. Unlike the thumbwheel tuning of its predecessor, the Ark-40, the TAC-1 comes with a convenient tuning knob. With a single press on the tuning knob, tuning toggles conveniently between 1 kHz and 100 Hz steps.

The TAC-1 is an excellent kit for intermediate to advanced builders. Like the NorCal-40A and the Sierra, the jacks and switches mount directly to the board, so there is no point-to-point wiring, and the documentation is excellent. However, the components density of the kit is high, and it would be rather difficult to align the synthesizer without the use of an oscilloscope.

The stability of the TAC-1 synthesizer and the digital readout make the radio ideal for serious beacon work. The radio is also very nice for operators who enjoy having a digital frequency display. The radio draws approximately 225 mA, which is needed to drive the synthesizer and LCD display. So the radio is still fairly well suited for portable use, albeit with a somewhat larger battery than the NorCal-40A or the Sierra.

The TAC-1 features RIT, AGC, narrow CW filter, and full QSK, and delivers approximately 3 watts output. The kit comes with a beautiful extruded aluminum case that is punched and screened and features an attractive plastic bezel for the digital display. The TAC-1 also comes with jacks and knob set, and a first class silk-screened printed circuit board.

The finished TAC-1 is a work of art. The populated printed circuit board is a virtual fiesta of components and colors.

KC1 Keyer, by Wilderness Radio. Memory keyer with frequency counter. Designed by the legendary QRP designer Wayne Burdick N6KR, the KC1 combines an unlikely and extraordinary juxtaposition of functionality: a memory keyer with a frequency counter that reads the frequency in CW!

Measuring only 2.5 x 0.8 inches, and drawing only 4 mA, the KC1 has become the first accessory that I put in each of my home-brew QRP rigs. The kit comes with fewer than 20 components, and can be assembled in about a half hour. Interfacing it to your QRP kit is a bit trickier, because you have to identify the best places to obtain a VFO signal, and fiddle with values of coupling capacitors to make it work. The KC1 also lacks the audio output to drive headphones, so the audio signal of the keyer must be injected into the final audio stage of your rig.

As of the writing of this article, Wilderness Radio was gathering user comments from many of the popular QRP kits, and furnishing interface instructions with the kit.

When finished, the KC1 can be programmed with up to four different VFO offsets to provide three-digit frequency readout accurate to 1 kHz. The KC1 also enables you to key in a three-digit frequency, and will give an alert tone when you dial to within 2 kHz of the frequency!

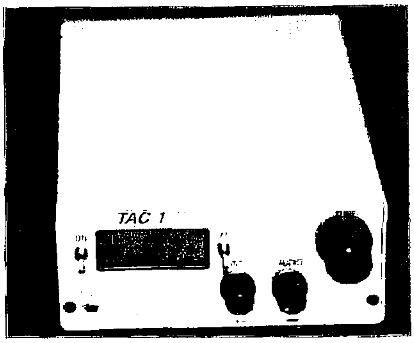
The KC1 is a respectable memory keyer, but lacks the dazzling array of keying features (like automatic sequencing of serial numbers) found in the Logikeyer III. The KC1 does include side-tone, weight control and multiple memory partitions. Keyer memories are stored in non-volatile memory; however, memories do not have separate buttons for each partition. For example, to access memory partition number three, the user presses the keyer button three times.

Mounting the KC1 is very easy, because the momentary switches used to operate the keyer also serve to mount the unit directly behind the front panel, or beneath the top cover of your transceiver. The keyer can also be mounted internally at a remote location.

Oldies But Goodies

This article would not be complete without mentioning a number of the great "classic" kits:

WM-1 Wattmeter, by Oak Hills Research. QRP with power ranges of 10 watts, 1 watt and 100 milliwatts.



TAC 1.

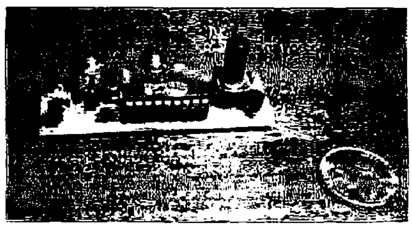
Explorer, by Oak Hills Research. Single-band superhet CW transceiver kit for 20, 30, or 40 meters. Features RIT, AGC and full QSK. 2-3 watts output. The kit comes with a punched and screened enclosure, jacks and knob set, pre-wound pre-tinned toroids, and silk-screened printed circuit board. Excellent transceiver for beginners.

PC1 Digital Frequency Counter, by S&S Engineering. LED display frequency counter with handsome extruded aluminum cabinet. Excellent frequency readout companion for home-brew QRP rigs, and a versatile piece of test equipment for your test bench.

Logikeyer III, by Idiom Press. The latest memory keyer in the Logikeyer series, the Logikeyer III now features six memory locations and non-volatile storage memory in EPROM. The postage stamp sized Logikeyer III has a robust array of superlative keying features and options such as automatic sequencing of serial numbers for contests.

I hope this article encourages you to build your first amateur radio kit, or to upgrade to build a new kit. Discover the joy of making a contact or working a new DXCC country on a radio that you built yourself. Happy building!

Very special thanks to my kit-building partner, Paul Stroud AA4XX, who built the TAC-1 and the NorCal-40A and who helped me troubleshoot the Cascade. Ernie AD4VA assisted me with the on-air testing of each of the radios.



KC1.

Getting Started: Tips for the Beginner

If this is your first kit, take a moment to prepare before building the kit. Before you open your first parts package, you may want to purchase a plastic compartmentalized parts box, which can be very handy for sorting and inventorying components. I found some nice boxes at a local housewares/kitchen supply store. Alternatively, Radio Shack™ has a suitable component box that costs a bit more (#64-552).

Read through the documentation very carefully *twice*, paying special attention to the information provided on component value data.

With every kit that I have built, there are at least a couple of components whose markings are hard to figure out. However, what seems complex when you first open the kit can be simplified by sorting out the parts, and checking off the items on the parts list supplied with the kit. When you've checked off all of the clearly marked items, you'll probably be left with only one or two confusing components, and it will be much easier to figure out which is which.

If you do not already own a soldering iron, I recommend a low wattage iron, (such as the Radio Shack™ #64-2067, a 30 watt pencil) with an extra fine pointed tip. This will be plenty of heat for fine printed circuit work.

I also recommend purchaseing a good soldering iron stand (such as the Radio Shack™ #64-2078) with a sponge tray. Using a good stand is an important safety consideration, and keeping the iron clean is one of the tricks to successful soldering. After every few solder joints, wipe the hot iron across the wet sponge to keep the tip clean.

Finally, you will probably need a good solder sucker (such as the Radio Shack™ #64-2098A). I have never completed a kit without soldering at least one component in the wrong place. The solder sucker will enable you to remove components with minimum wear and tear on the printed circuit board.

Answers to Some Frequently Asked Questions:

•*Can trim capacitors go in the wrong way?* No. Resistors and ceramic disk capacitors can't be put in the wrong way either.

•*Can electrolytic capacitors go in the wrong way?* Yes. Electrolytic capacitors have a positive and a negative side. The negative lead is shorter and is marked with a stripe and a "minus" mark. The positive lead is longer, and may have a small "+" sign, or may be unmarked. Tantalum capacitors also have a positive and negative polarity, with positive marked by a "+" sign.

•*Can integrated circuits go in the wrong way?* Yes. When you put in the ICs, be certain to match up the dot or notch on the IC with the dot or notch on the layout diagram. You may also notice that each of the sockets has a notch. Align the notch so that it is oriented with the dots.

•*How are crystals installed?* Crystals can go in the circuit in any arrangement, and they do not have a positive/negative polarity. It's helpful for crystals to be installed approximately 1/8-inch above the circuit board so that the crystals do not break if the printed circuit board is subjected to mild shock or vibration.

•*How are the diodes mounted?* For diodes that are lying flat on the board, match the black band of the diode with the band on the silk-screened board.

•*How is magnet wire on toroids soldered?* Theoretically, magnet wire uses a coating which is melted off during soldering. I have found, however, that the coating does not melt off completely, and that the resulting solder joint does not make a good connection in all circumstances. It is safer to carefully scrape away the coating with an X-acto blade prior to soldering.

Troubleshooting

If you are having any problems, remember that most problems boil down to a mistake in wiring, component placement, or a solder defect. Before calling tech support, check the following:

•*Solder defects*: The most common defect in soldering is a solder bridge. This occurs when solder connects two pads that should not otherwise be connected. Solder bridges can be fair-sized globs of solder that must be removed with a solder sucker or braid, but can also be tiny threads of solder that are easily removed with an X-acto knife. Study your work under a magnifying glass and good work light, and examine it carefully for solder bridges before you apply power to your kit.

•*Wiring:* It's very easy to reverse wires in the final hookup stage of your kit. Carefully check through all of your wiring for defects.

•*Components*: Carefully check your component placement and polarity one by one. Remember, transistors, integrated circuits, electrolytic capacitors and diodes have to be installed with the right orientation.

•*Lead Lengths*: Check to make sure that component lead lengths and wires are as short as possible.

•*Noise in the receiver*: Change the power supply or use a battery to see if the noise disappears.

•*Dead receiver:* Before you align your kit (usually peaking up a series of inductors and capacitors) it's not at all unusual for the kit's receiver to sound completely deaf. Patiently go through the alignment procedures to peak up your receiver before you decide that your receiver isn't functioning properly.

If you have double-checked all of the above items, it may be time to call the kit supplier. When you call, be sure to have a carefully prepared list of questions handy so that your tech support call is as efficient as possible.

You might also be able to get help from an experienced kit builder in your local radio club. If all else fails, most of the companies will troubleshoot and align your radio for a set fee.

Good luck!

73's DX Dynasty Award

Number 26 on your Feedback card

This is the current list of DXDA award winners. The DX Dynasty Award is the most enjoyable DX award around. Any correspondence concerning DXDA should be addressed to DXDA, c/o 73 Magazine, 70 Route 202 N, Peterborough NH 03458.

NEVER SAY DIE

Continued from page 8

room? I forget how many hundreds of billions of dollars the whole thing was estimated to cost.

My question resulted in more obfuscation, and a shift to an even higher level of encrypted language. After my asking my question about four times I finally got a grudging yes, that's about what it all adds up to. I told the colonel he and the Air Force master minds who thought up this one were crazy. I suggested they use technology instead of brute force to solve their problems, and that if they insisted on pursuing this I'd raise all the hell I could, and do my best to embarrass them for such a stupid and expensive idea.

Well, it never happened, though I don't know if my grain of sand's worth of resistance had any part in their abandoning the project. Anyway, we didn't lose 450 MHz back in 1956.

While I was there they introduced me around. One of the chaps I met was in charge of assigning berths to the media on Navy ships. I said, hmm, what have you got open? Well, they had a supply ship going to Antarctica with an opening. I told 'em to hold it for me. It was a three-month trip, so I didn't have the time to go, much as I'd have liked to. But I thought I might be able to talk Jim Morrissett K2OLK, who'd been my assistant editor for a couple of years, into making the trip on assignment. I asked what the possibility was of my reporter taking along a ham station to use on the ship. No problem, except I'd have to get permission from the captain of the ship.

Sure enough, Jim liked the idea, so I sent him a Retina IIIc 35mm camera for the photos and arranged for a Hallicrafters transmitter and receiver for the ship. Then I set about getting permission from the ship's captain. He said he had no objection, but of course I'd have to get it okayed by the Navy Chief of Communications, Admiral Bruton. The Admiral nixed the ham station, for no reason I could see, and he flatly refused to discuss the matter.

So I wrote an editorial explaining exactly what had happened. And, since I had my editorial work done a few weeks ahead of schedule, I took off for a scuba diving trip to Acapulco. Well, there was this fantastically beautiful British girl I'd met in Bermuda who was also into diving, and who was working for a dive shop there. But that's another story. The diving was great and I got some spectacular pictures.

But when I got back to the US I found myself in Great Big Trouble. It seems that my assistant editor, Art Brothers W7NVY, thought my editorial didn't have quite enough zing to it, so he edited it a bit. The word "traitor" was added and Admiral Bruton was not amused. The publisher, Art, and I were soon facing

Simple Secondary Frequency Standard

Stay within your legal frequency.

J. Frank Brumbaugh KB4ZGC
P.O. Box 30
Salinas PR 00751-0030

Every ham is required by the FCC to make certain his or her transmitted signals are entirely within the band or subband appropriate to the license class. Operating outside assigned frequency band segments invites "Pink Slips" from the FCC, requiring explanation as to why the offense occurred and what means are being used to prevent it happening in the future. Continued off-frequency operation can result in fines, possible jail time, and even cancellation of your license. Because of this, most hams have either expensive, fancy commercial transceivers with digital frequency readout controlled by a crystal, or they build and use a secondary frequency standard, commonly called a "crystal marker generator." It is for hams whose budgets don't include a thousand dollars or more for a fancy commercial transceiver loaded with bells and whistles that this article is presented.

There are a number of marker generator circuits presented in the ham magazines as well as in the *ARRL Handbook*. Most, however, specify the use of a crystal at 100 kHz or 1 MHz. A glance at the listing of crystals for sale in any mail order parts dealer's catalog will show that crystals of these frequencies are rather expensive. It is possible (and very simple) to build a marker generator based on a much higher crystal frequency, *plus* it has advantages in long-term stability over the lower frequency crystals usually specified. It also saves money, because surplus microprocessor crystals usually cost only about $1.00.

Every crystal, regardless of cost, is subject to "aging" which results in a change in frequency, although some crystals are far more stable over time than others. Hams are interested primarily in 100 kHz and 25 kHz marker frequencies because these accurately mark the edges of most bands and subbands. A low-frequency crystal drifting off frequency causes these markers to drift, too, which could result in out-of-band operation, with the unfortunate consequences mentioned in the first paragraph. However, a crystal of a frequency of 10 MHz which also drifts a bit will not cause the same amount of error as the low-frequency crystal, because its frequency, and drift, is divided by a factor of 100 at 100 kHz, and 400 at 25 kHz. In "real life," after the 10-MHz crystal has been adjusted to exactly 10 MHz, either by using a frequency counter or by zero beating the crystal with the signal from WWV, any drift in crystal frequency due to aging will be so minute after being divided down to the desired 100 kHz or 25 kHz that it cannot be heard. For all practical purposes, the divided marker frequencies will remain accurate over time.

"This marker generator provides accurate marker RF signals at 1 MHz, 100 kHz, 50 kHz, 25 kHz, and 10 kHz when the crystal oscillator is zero beat with WWV or otherwise set to exactly 10 MHz."

The secondary frequency standard—the crystal marker generator described here—is based upon the use of a 10-MHz surplus microprocessor crystal as its standard. It is called a "secondary" standard because it is set to frequency with a frequency counter or by zero beat with the carrier transmitted by WWV. Primary Standards are those maintained by the National Bureau of Standards, which are very precise and very expensive, and serve, among other things, to establish the carrier frequency of WWV and WWVH.

This marker generator provides accurate marker RF signals at 1 MHz, 100 kHz, 50 kHz, 25 kHz, and 10 kHz when the crystal oscillator is zero beat with WWV or otherwise set to exactly 10 MHz. It uses the fewest, most common, inexpensive, and readily available components: one crystal, one 5-volt regulator, five TTL logic ICs (commonly called "chips"), three 1/4-watt resistors, two disc ceramic capacitors, one small trimmer capacitor, one ON-OFF switch, one 9-volt battery, and one single-pole five-position wafer switch. The total cost, using all new "surplus" parts, will be less than $10.00. This is very inexpensive insurance to make certain all your transmissions are on legal frequencies!

Circuit Description

Fig. 1 is the schematic diagram of this instrument. Refer to this illustration for the following discussion. Battery B1 (9 V) provides power through S1 to a 5-volt regulator, U6, a 78L05, which provides regulated +5 VDC to the five ICs—chips—which provide all the marker frequencies from 1 MHz down to 10 kHz.

U1, a 74LS00, is a quad two-input NAND Gate. Two of its sections, U1a and U1b, are connected to form an oscillator circuit controlled by the 10 MHz crystal, Y1, which is adjusted to frequency by trimmer capacitor C2. The remaining two sections are connected to form inverters and provide the output signal of 10 MHz at pin 11.

The 10-MHz output from U1 is applied to the pin 1 input of U2. U2, a 74LS90, is a divider connected to divide by 10. U2 divides this 10 MHz to 1 MHz and provides its output at pin 12. This 1 MHz signal is routed to the first position terminal of S2, and also to the pin 1 input to U3.

U3 is a 74LS90 divider also connected to divide by 10. It divides the 1-MHz input to 100 kHz and provides its output at pin 12. This 100-kHz signal is routed to the second position terminal on S2, and also to the pin 11 input of U4.

U4 is a 74LS74, a dual flip-flop configured to divide by both two and four, producing 50 kHz at pins 3 and 9, and 25 kHz at pin 5. The 50 kHz from pins 3 and 9 is routed to the third position terminal of S2, and also to the pin 1 input of U5. The 25-kHz output from pin 5 of U4 is routed only to the fourth position terminal of S2. U5 is a 74LS90 configured to divide by five. It divides the 50-kHz input and produces a 10 kHz signal at pin 11. This 10 kHz signal is routed to the fifth position terminal of S2.

C3 connects from the wiper terminal of S2 to the output connector of the builder's choice. C3 also serves to block the DC voltages of the divider chips from appearing at the output.

Construction

This unit may be constructed on a piece of perfboard, or one of the general purpose printed circuit boards available from Radio Shack. It could also be constructed "dead bug" style by gluing the chips upside down on a piece of circuit board stock, perfboard, plastic, even wood. Lead lengths should be kept reasonably short, especially around U1. Other leads are not critical; just use common sense.

Caution: Pinouts of all chips and the 78LO5 regulator are illustrated in Fig. 1. Pinouts of all chips are shown from the top of the chip. Pinout of the regulator is shown from the bottom. Make certain you are connecting to the specified pins!

If you use perfboard or a printed circuit board you may install 14-pin DIP sockets and do all your wiring before plugging the chips into the sockets. Sockets are not necessary but you may use them if you wish.

In soldering to the pins on the sockets or chips, and to the pads on a printed circuit board, be extremely careful, not only to make solid, shiny solder joints, but to avoid "solder bridges," which occur when too much solder is applied, accidentally bridging two adjacent pads or pins. Use a 25- or 30-watt soldering pencil with a small tip, and always use rosin core solder, preferably marked "60-40" or "63-37," indicating the tin and lead proportions in the solder.

Warning! Never use acid core solder in electronics: It will corrode the connections and ruin anything built with it.

Before applying power, carefully inspect every connection, every solder joint. Correct any poor solder joints and eliminate any solder bridges. If you use DIP sockets, be absolutely certain the chips are inserted in the proper locations and in the proper heading—pin 1 on the chip to pin 1 on the socket. It will be helpful if you mark (with a dot of white paint, perhaps) the position of pin 1 on top of each chip, and also on the corner of each socket.

Because this marker generator is a digital circuit, it will either function perfectly or not at all. If it doesn't work you have made a wiring error, or you have plugged a chip into the wrong socket. Go back and check *everything* against the schematic diagram in Fig. 1.

Calibration

If you own, or can borrow, a frequency counter that you know is accurate, use it with a probe to measure the frequency at pin 11 of U1. Using an insulated screwdriver which fits the slot in C2, slowly adjust C2 for a frequency of 10.000000 indicated on the frequency counter. Then also check the frequency at each marker output from S2. You should find 1.000000, 0.100, 0.050, 0.025, and 0.010 indicated on the counter. If any output frequency is missing or in error, you have made an error during construction, which you will have to find and correct.

You can also zero beat this unit against the carrier of WWV. Usually, 10 MHz is the most likely frequency where WWV can be heard throughout the USA, Canada, and northern Mexico. Elsewhere in the world WWV also transmits on 2.5, 5.0, 10.0 and 15.0 MHz. Any frequency where WWV can be heard clearly can be used for calibration.

With a receiver tuned to WWV, and S1 on the marker generator in the ON position, either place the marker generator close to the receiver, or connect, with a piece of wire a couple of feet long, the receiver antenna connector to the whip antenna if you are using a typical "world band" portable radio. With an insulated screwdriver, adjust C2 as described above until you hear the squeal of the marker crystal beating against WWV. Adjust C2 until the signals are in zero beat or very close. Besides the time ticks at one-second intervals there is a 600-Hz tone transmitted most of each minute. The time in Coordinated Universal Time (UTC) is announced by a male voice (USA) or female voice (WWVH

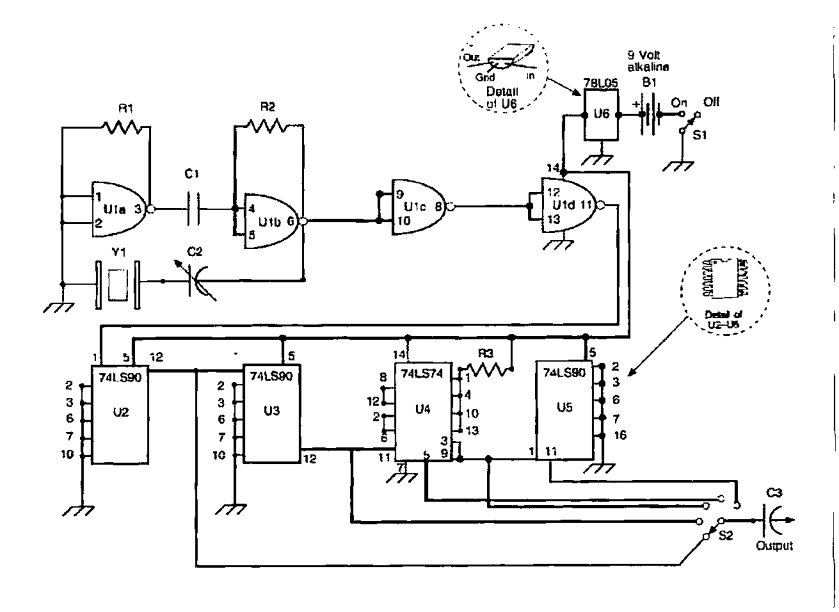

Fig. 1. Schematic for the simple secondary frequency standard.

Hawaii) at the end of each minute. Forty-five seconds after the voice announcement begins a silent (except for time ticks) period 7-1/2 seconds long. For greatest accuracy of calibration, adjust C2 to as close to a perfect zero beat with WWV's carrier as possible. This period should be long enough if you were close to zero beat earlier, but if necessary you can wait one or two minutes and recheck zero beat until you are satisfied it is the closest you can come.

Caution: Be certain the screwdriver you use to adjust C2 is non-metallic. C2 has both terminals floating and is a critical component in the oscillator. Using a metal screwdriver tip will make it impossible (due to "hand capacitance") to get to an accurate zero beat.

Now check the marker frequency at each position of S2 by tuning the receiver carefully and checking against its dial. Unless the receiver dial has a digital readout it will probably not be exactly accurate, but will be close enough that you can tell if the desired marker frequency is missing or if it is far off frequency. Either result indicates an error in construction which you will have to locate and correct.

This completes calibration of your secondary frequency standard. It can be used and totally trusted for years, although a recheck of the crystal frequency as described above should be made after six months, and then once every year from then on. A slight adjustment of C2 may be required to put the crystal frequency back "on the nose."

Operation

As mentioned earlier, this instrument either works perfectly or it doesn't work at all. If you have followed directions, it will work each time you turn it on. The output level from the marker generator is fairly high, S-9 or better if fed directly into the antenna connector of your receiver. Often it will be preferable to add a few feet of wire to the output of the marker generator and allow it to radiate its signals to your station receiver. This is the preferred method if you are using it to pinpoint the edge of the band or subband you intend to operate on. However, it has many other uses, discussed below.

Hams who build their own transmitters and receivers need to be able to calibrate their analog dials. Too, if your receiver does not have a digital readout, you will need to use the marker generator to locate specific frequencies—that is, within 10 kHz because the lowest frequency markers are 10 kHz apart.

Calibrating a Receiver Dial

To begin, you'll need a known frequency. The simplest way of determining this is to tune the receiver to around where you think the low edge of the ham band should be. Note the activity on the band. At the lower edge of this activity—1.8, 3.5, 7.0, 14.0, 21.0 or 28.0 MHz—turn on the marker generator and set S2 to 1 MHz. Tune the receiver for zero beat—it is assumed either a BFO or product detector is included in the receiver. Mark the dial with the proper band edge frequency. Then, selecting other frequencies with S2 you can locate and mark frequencies within the band, even down to every 10 kHz if desired.

A slightly more complicated way of locating known frequencies is to build a small crystal oscillator using a color-burst crystal whose nominal frequency as marked is 3.579545 MHz. Duplicate the U1 portion of the schematic diagram, Fig. 1, remembering to supply +5 VDC to the 74LS00 chip. Do not include C2, but connect the crystal directly between pins 1-2 and 6. This crystal will produce frequencies either within or very close to every HF ham band between 80 and 10 meters, including WARC bands. However, you will have to check the crystal fundamental frequency with a frequency counter because it *will not* be exactly 3.579545 MHz. When the fundamental frequency is accurately known, use a calculator to multiply the fundamental frequency and note the frequency of each harmonic. Keep a copy of these known frequencies for future reference. Because the harmonics of this oscillator are more than 3.5 MHz apart it is easy to locate the desired known frequency. With this as a starting point, and using the required output selected by S2, you can easily locate WARC bands as well as calibrating these and other HF bands.

Calibrating a VFO Dial

A calibrated receiver with a digital readout can be used easily to calibrate a VFO dial without use of the marker generator. Merely tune the receiver to the desired frequency and zero beat the VFO to the receiver. Then mark this frequency on the VFO dial, repeating as desired. If your receiver has an analog dial and you have calibrated it with the marker generator, you can tune the receiver to the desired frequency as described in the preceding paragraph, repeating this procedure as necessary. If the receiver you are using has an analog dial, such as a portable shortwave receiver that covers the ham band frequencies, you can locate the lower band edge by setting S2 at 1 MHz and tuning the receiver slowly while looking at the receiver dial closely until you achieve zero beat. Dial scales on these receivers are inaccurate but usually not so far off that the proper 1-MHz signal cannot be located accurately. It is assumed the receiver contains a BFO or product detector and is capable of receiving SSB and CW. If this is not the case it is not recommended that this receiver be used. While it is possible to locate—approximately—the 1-MHz signal by a peak in the level of the rushing noise from the receiver, this is not precise enough to be trusted. You'll have to either borrow a suitable receiver or take your VFO to a local ham who does have a usable receiver.

Conclusion

Although this crystal marker generator produces usable harmonics at frequencies well above and below the MF and HF ham bands, it is intended for hams operating from 160 through 10 meters. ("Lowfers," unlicensed but legal operators in the 160-190 kHz band, can also use this unit to calibrate the receivers and VFOs of their 1-watt stations.) Because it covers such a broad frequency spectrum with signals of known frequency, spacing and accuracy, the marker generator can take the place of a less accurate signal generator in general radio servicing, including calibration checking and alignment. Despite its many other possible uses, it is presented here primarily as a useful aid to prevent accidental operation on frequencies not available to your license class. 73

Parts List

B1	9-volt alkaline battery
C1	0.01-µF disc ceramic capacitor
C2	5-60-pF trimcap, Murata etc.
C3	47-pF disc ceramic capacitor
R1, R2	560-ohm watt 5% resistor
R3	1k-ohm watt 5% resistor
S1	SPST toggle or slide switch
S2	1-pole 5-position wafer switch
U1	74LS00 quad 2-input NAND Gate
U2, U3, U5	74LS90 Decade Counter
U4	74LS74 Dual-D Flip-Flop
U6	78LØ5 5-volt regulator
Y1	10.000000-MHz microprocessor crystal

NOTE: The output connector suggested in Fig. 1 can be a binding post, RCA jack, or any other type connector you wish to use.

The Tiny Tic-Tac Tester

This useful and easy-to-build tester is a good first-time project.

Sam Ulbing N4UAU
5200 NW 43rd St. #102-177
Gainesville FL 32606

It is often useful to be able to check the voltage of your batteries. For instance, you may wonder if your handie-talkie is charged or not. Unfortunately, most batteries, especially rechargeable batteries, do not change voltage much between being fully charged and nearly discharged, so a very accurate meter is needed. Good digital multimeters will work well, but they are expensive and bulky. The tiny Tic-Tac tester is an alternative that is very small (you can carry it in your shirt pocket), inexpensive and quite accurate. The tester doesn't require batteries to work since it takes the little power it needs from the source it is testing! Photo A shows one I built in a Tic-Tac container, hence the name. As you can see, it is small—about 1-1/2" x 2" x 1/2" thick. An experienced builder could put it in an even smaller case.

How It Works

Fig. 1 shows the schematic of the tester. The only parts used are one IC, 10 LEDs for display, four fixed resistors and one potentiometer. If you use the available (from me) PC board you will probably spend more time putting the project in an enclosure than you will soldering it together!

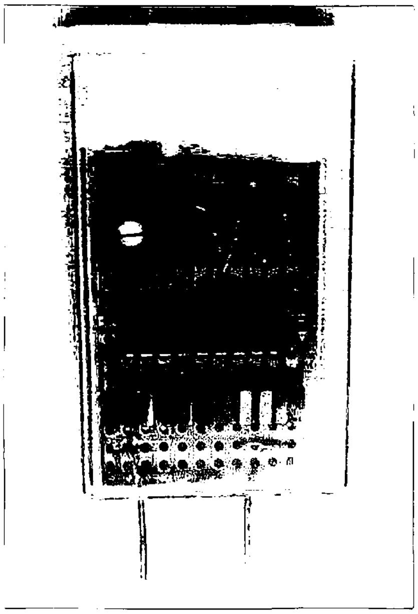

Photo A. The tiny Tic-Tac tester.

The heart of the tester is an IC called the LM3914 which contains 10 voltage comparators connected to a 10-step resistive divider and an on-board voltage reference. The comparators on the chip work like any standard comparator. When the voltage on the minus pin is greater than the voltage on the plus pin, the output of the comparator goes to ground and lets current flow through the comparator output port. When the minus pin voltage is less than the plus pin voltage, the comparator output floats and no current can flow to ground. The internal comparators are used to turn on the display LEDs. As the signal voltage increases, more LEDs will turn on. What values of signal voltage will turn on the LEDs depends on the "control voltage" at the positive terminal of each comparator. By setting a reference voltage across the internal voltage divider of the LM3914, the comparators can be made to turn on in 10 equal steps of one-tenth the voltage across the divider. The LM3914 makes it easy to set any desired voltage across the divider.

The voltage to be measured, which powers the chip, goes to pins 2 and 3 of the LM3914 (see Fig. 1). A voltage divider, formed by R4 and R5, reduces the voltage by half and applies it to pin 5, the buffered signal input pin. It is important to use this divider because the voltage to be measured must be at least 1.5 volts *less than* the voltage powering the chip.

R3 is connected between pin 7 and pin 8, which is the on-board reference voltage. Since the reference voltage is known and so is R3, a known current is

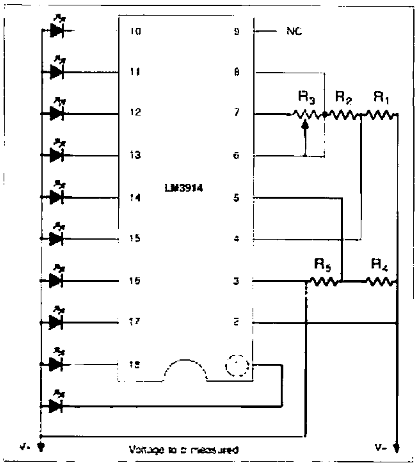

Fig. 1. Shows the schematic of the Tic Tac Tester. It's easy to build, accurate and can be carried in your shirt pocket.

generated through R3 ($I1 = VRef \div R3$). This current (plus a small current from pin 8) flows to ground through R2 and R1. By selecting R1 and R2, any desired voltage can be set at points VLow and VHi. Connecting pins 4 and 6 to VLow and VHi gives us the desired control voltages for the comparators.

A control switch not shown in Fig. 2 lets the user program how the LEDs are turned on. If pin 9 is left floating, only one LED at a time will be turned on (called dot mode). As the voltage increases and a new LED comes on, the last LED will turn off. This mode is useful for low power use. If pin 9 is connected to pin 3, each LED will stay on (called bar mode). When the input voltage reaches the VHi value, all the LEDs will be on.

The LED display has an advantage over a digital display because it is easy to read at a glance even from a distance. By making the LEDs different colors, it is possible, for example, to display low voltage as red, OK voltage as green, and high voltage as yellow.

Building A Tiny Tester

What follows is somewhat technical; if you are not interested in how I got my

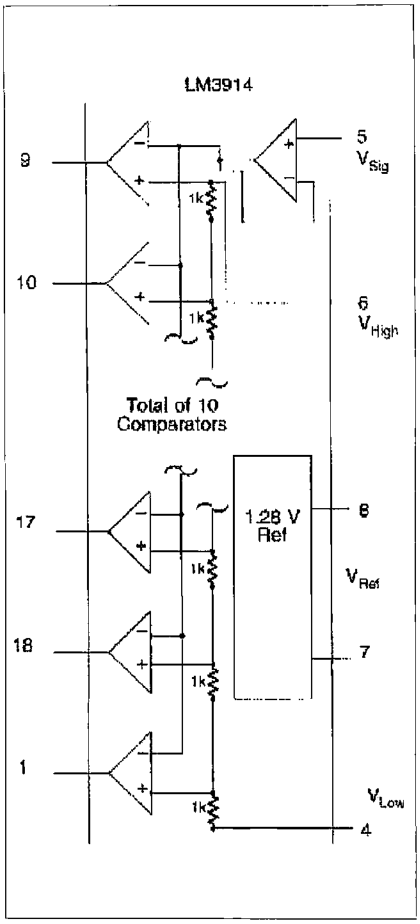

Fig. 2. A look inside the LM3914, the chip has a total of 10 comparators.

resistor values but only want to know what values to use for your tester, you can go directly to Table 2. Many variations of this meter can be built. I will discuss the one I built to check the voltage of my Kenwood handheld. It has nickel rechargeable batteries and the pack says it is 8.4 volts. Because "nominal" voltage for NiCds is 1.2 volts, I know it has seven cells.

A fully charged NiCd (see Fig. 3) is about 1.40 volts, and when it reaches about 1.14 volts it is pretty much discharged. For my tester, I chose:

V_{Hi} = 1.40 x 7 = 9.80 volts

I wanted the first LED to come on when the battery voltage was greater than

1.14 x 7 = 7.98 volts

As you can see from Fig. 2, the first LED will not turn on until the signal voltage is equal to V_{Low} plus one-tenth of the internal voltage divider difference. With a voltage across the divider of:

9.8 – 7.9 ≈ 2 volts

Each step is about 0.2 volts, so I set

V_{Low} = 7.98 – 0.2 = 7.8

Another design consideration was current draw. Since I was powering this meter from the batteries I was measuring, I wanted a small current draw. Obviously I chose "dot mode" rather than "bar mode." Further, the chip has built-in current limiting of the LED, which is why no resistors are needed in line with them. The current through an LED is limited to 10 times the current through R3. I decided to make LED current about 5 mA so the total current draw would be 10 mA. Although the LEDs are not as bright as if they had a full 20 mA, the LEDs I used are clearly visible in daylight. The value needed for R3 to get this current is:

R = f(V,I) = f(1.28 volts,0.5 mA) = 2560 Ω

I used a potentiometer for R3 because the accuracy of the reference voltage is only about ±5% and to measure the NiCds I needed more accuracy. The potentiometer allowed me to fine-tune I1 for more accuracy on VLow and VHi.

Since I knew I1 and the voltages I wanted at points VLow and VHi, I could determine R1 and R2:

R1 = f(1.12 Volts,0.5 mA) and R2 = f((1.4 – 1.12),0.5)

It's that easy. Well, almost that easy. In fact better accuracy is obtained by including a few other factors. The internal 10kΩ divider acts as a parallel resistor to R2 and there is also a small current from pin 8 to drive the reference voltage. Table 1 shows the actual calculations I used to include these factors and Table 2 shows values for some common battery configurations.

Note in Table 2 that, for seven cells, the 10 steps from 1.12 to 1.40 are each about 200 millivolts. This is a precision of:

f(0.200,8.00) = 2.5% ± 1.25%

This is a pretty precise device. This fact needs to be considered when building the meter. Most resistors are ±5% resistors so they have four times the error of our meter. Obviously ±1% resistors will work much better. In fact, I put together several ±5% resistors and measured their actual values to get less than 1% error.

Once you have soldered the meter together, you need to make only one calibration. Connect the battery pack you plan to measure and measure V_{Low}. Adjust R3 until V_{Low} is the desired value. That's it.

I put a couple of rather stiff wires off the edge of the PC board. By filing a small set of notches in the top of my

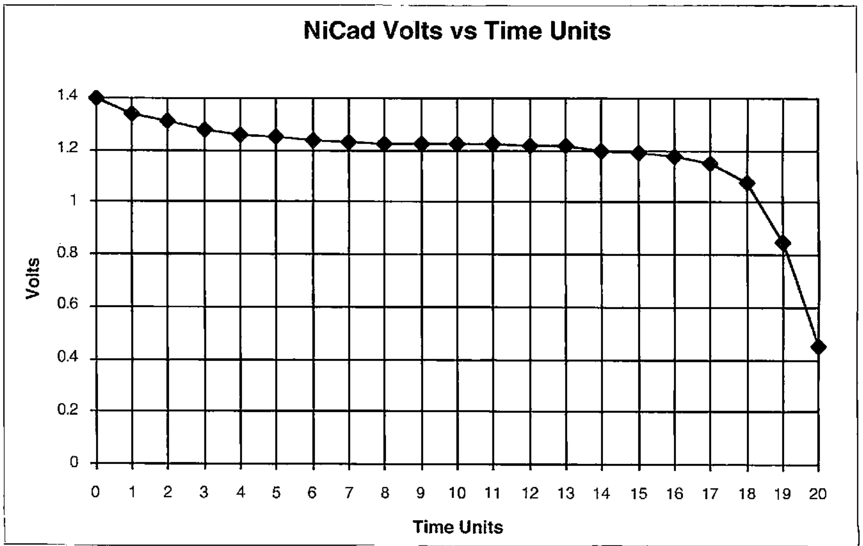

Fig. 3. Typical voltage vs. time curve for NiCd battery under load.

handheld's battery pack, I was able to insert the tester and touch the battery terminals. This makes it easy to check battery voltage.

Limitations And Constraints

Such a simple device naturally has a few limitations:

1. You need to measure at least 3 volts for the LM3914 to work.
2. Total divider voltage ($V_{Hi}-V_{Low}$) should be at least 200 mV in bar mode and 500 mV in dot mode for best results.
3. Absolute max for supply voltage is 25 volts.
4. To increase the accuracy I did not include a protection diode. Connecting a battery backward will likely destroy the LM3914. So far, I have not tested this feature!
5. The voltage to be measured at pin 5 must be at least 1.5 volts *less than* the supply voltage.

Obtaining the Parts

Parts are readily available from the usual suppliers: Mouser, MCM, JDR Micro Devices, etc. A PC board is available from me for $5. If you prefer to buy the PC board and all of the parts (except the Tic-Tac box), that'll be $15. Please specify which of the versions in Table 1 you want to build so I can send the correct 1% resistors. Prices include shipping in the US. Florida residents please add sales tax for your county *(or move to New Hampshire, where there is no sales tax...Wayne).*

Table 1 Equations to select resistors

$R_3 = f(1.28, I_1)$
$R_1 = f(V_{Low}, (I_1 + 0.075))$
$R_2' = f((V_{Hi} - V_{Low}), (I_1 + 0.075))$
R_2' is a temporary variable used to make calculating R_2 easier
$R_2 = f(R_2' \times 10, (10 - R_2'))$

I1 is in mA
R_1, R_2, R_3 are in kΩ
V_{Hi}, V_{Low} are in Volts
R2' is a temporary variable used to make calculating R2 easier.

Remember: because of the voltage divider, V_{Lo} and V_{Hi} will be half the voltage of the battery you are measuring.

NOTE: Voltages shown are actual voltages of the battery being measured. When calculating resistor values remember to account for the voltage divider of R4 and R5.
R4 = R5 = 10.0 kohms

Table 2. Some component values for selected battery configurations.

A New Look at the VXO

80 through 10 meter coverage using a TV color burst crystal.

Ken Cornell W2IMB
225 Baltimore Avenue
Point Pleasant Beach NJ 08742

In my experimental endeavors with frequency generating devices I became very fond of the Pierce oscillator, not only for crystal control but as a VFO using a coil in series with a blocking capacitor in lieu of the crystal. The basic Pierce oscillator circuit is described in almost all radio handbooks, so it needs no detailed mention here. However, it is always shown as a crystal-controlled device. By using quality parts and voltage regulation, it can be used as a respectable VFO.

The Coils

I decided to experiment using a coil in series with the crystal and an adjustable ferrite core in the coil to see how much of a frequency change I could get. There is a similar circuit shown in my *ARRL Handbook*, but they use a split-stator variable capacitor for the tuning and claim a maximum swing of some 15 kHz. I was looking for a much higher frequency excursion. Years ago, I wound a series of "honeycomb" coils ranging in size from 50 turns to 450 turns. I connected the 50-turn coil in series with a TV color burst crystal (3.57945 MHz) and poked a 1/4" ferrite rod into the coil field. I was surprised to see a frequency swing of 30 to 40 kHz. I should mention at this point that my coils were wound with Litz wire. This is an important point!

I fooled around for hours winding many coils using #28 to #36 enameled wire, but could not get satisfactory performance. I finally found that a coil with 60 turns of 14/44 Litz wire did the trick; the result is shown in Fig. 2. Why the solid wire would not work is still a mystery.

The 14/44 Litz wire that I used may be hard to find, but I've noted that 10/44 Litz wire is available from LF Engineering Co., 17 Jeffry Road, East Haven CT 06512, and from Amidon Associates, Inc., 2216 Gladwick Street, Dominguez Hills CA 90220.

> ***"This circuit could be ideal for QRP transmitters and transceivers."***

The coil assembly shown in Fig. 2 should be closely followed as far as the coil, ferrite rod and 8-32 aluminum screw feed are concerned. The coil is wound between two flanges cut from cardboard and spaced 1/4" apart. The coil contains 60 turns. The coil form sleeve can be of any insulating material and should have an ID of 1/16" to 3/32" larger than the ferrite rod.

The most difficult part of the assembly is to cement the 8-32 aluminum screw to the ferrite rod and ensure perfect alignment. The screw I used had a round head. I wrapped several turns of masking tape on the threads and chucked it up in my drill press. I placed a flat file on the drill press plate and ground the head flat. I then used the file and ground the head diameter down to 1/4". Next I wrapped masking tape around a 1" length of #8 ferrule to make the OD 1/4", then slipped it onto the screw. I then inverted a length of aluminum angle to form a trough and placed the ferrite rod in it. I applied epoxy cement to the head of the screw and placed it with the ferrule in the trough, then pressed it to the rod. This completed the screw and rod assembly. The balance of the coil construction should be self-explanatory, as shown in Fig. 2.

In operation, the coil will exhibit some frequency change when tuned by hand more than 15 to 20 kHz from the crystal frequency. I tried shielding the coil with a 1-1/2" diameter aluminum can and it lost the frequency change ability. However, when mounted within a Radio Shack™ 3" x 5-1/4" x 5-7/8" cabinet (RS #270-253) with the oscillator circuit, it performed satisfactorily. There was no problem with hand capacity detuning. I see no reason why a larger diameter ferrite rod can't be used using the same basic design and I hate to discourage experimentation.

Assembly

The oscillator circuit is shown in Fig. 1. I assembled it, without the coil, on a piece of perf board. C1 and C2 are 100 pF NPO disc capacitors. C3 and C4 are disc type. C5 should be the smallest value that will still provide enough drive to a buffer or multiplier stage. Quality

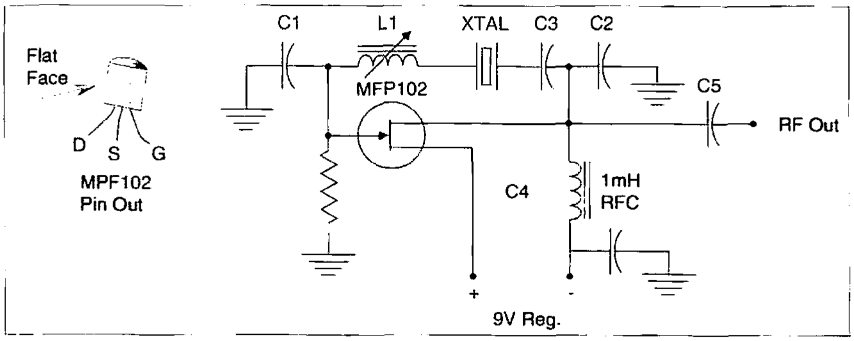

Fig. 1. Oscillator circuit.

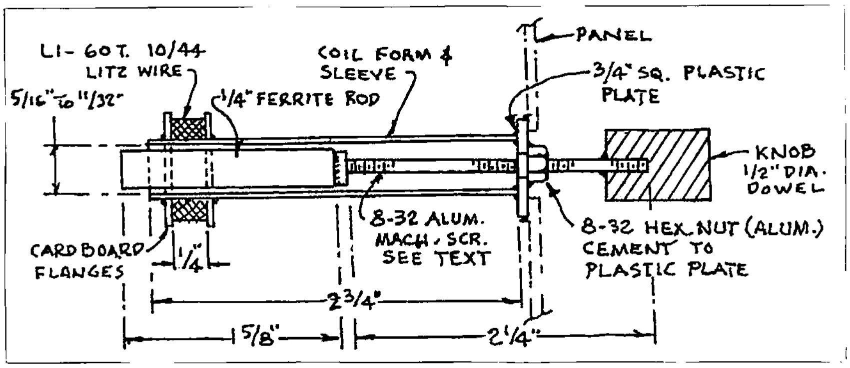

Fig. 2. Construction details.

parts and sturdy construction should be used, as well as voltage regulation.

For additional coverage of the 80 meter band, extra crystals could be used to suit the desired range.

With the ferrite rod withdrawn from the coil, the fundamental frequency is somewhat lower. Mine tuned to 3.578 MHz. At full penetration (the rod centered on the coil), to 3.489 MHz. Of course, the permeability (μ) of the rod will affect this. I would suggest, if possible, using a rod with a μ of over 800.

A frequency counter can be used on the output, or your receiver can be used to zero in on a desired frequency. Tuning is accomplished by turning the screw feed. It will take a little time to become familiar with the tuning as the feed vs. the frequency spread is not linear.

I used DURO™ "QUICK GEL" epoxy cement for all structural connections. It is the first single-solution epoxy cement that I have used that doesn't dry up in the applicator after a few uses. It is extremely strong and sets up fast. For cementing the coil flanges, I used household-type plastic cement.

I have not tried this scheme using other types of oscillator circuits, but you never know what a real "dyed-in-the-wool" experimenter will come up with.

While I don't claim extreme stability at the lowest frequency excursion, I do feel that this circuit could be ideal for QRP transmitters and transceivers.

I might note that many of the transistor AM radios use Litz wire for the antenna coil and some of the larger types use ferrite rods for the antenna (not the flat bar type). Check around for defunct sets. 73

Andris "Andy" Neimers VE7FJT. It did my heart good to see John Wagner W8AHB and you tackling the "studious indifference" shown Nikola Tesla by large segments of the US science establishment, even today. I first twigged to the fact that something really rotten was being perpetuated after reading an article on Tesla written by Commander E.J. Quinby in the November 1972 issue of *73*. (As a child he was an eyewitness to Tesla's radio controlled boat demonstration of 1898). Checking some scattered sources, I quickly concluded that a massive snubbing was indeed being perpetuated, given what this genius had invited in his lifetime. It also came to mind that even though I worked as a newspaper reporter for eight years in St. Catharines, Ontario, and visited Niagara Falls hundreds of times, I'd seen no evidence of Nikola Tesla acknowledged as the creative genius behind the power station complexes on both sides of the border. It's quite ironic since there is some evidence that this snubbing was, and still is, based on the hometown boy Edison versus offshore-born Tesla, in Smilijan, Croatia, even though Tesla himself said that getting his US citizenship in 1891 was one of the most cherished and proud moments of his life. The perpetuation of the Edison mystique, and the exclusion of Tesla, extends into US corporate speechwriting - something I am very familiar with. Even today, Edison quotes, wisdoms and sayings abound in speech reference materials, although I believe that some serious research would reveal that much of this Edison folklore is more "Hollywood" than from the man himself. For anybody who wants to get an insight of Tesla's brilliant range of inventions, I would suggest they read *Tesla - Man Out Of Time* "by Margaret Cheney: Dorset Press, New York 1981. I might warn you though that it is depressing reading since It brings Into sharp focus the struggle he had all his life for due recognition. Tesla had one serious weak spot which he wasn't capable of resolving, and it was the fact that his mind was so brilliant, creative, and quite easily bored, that he didn't and wouldn't take the time to bring too many of his projects to market before leaping off into another area of enquiry. Speaking of the "father of radio" aspect, John's short article also didn't have room to mention that among Tesla's accomplishment's was the first demonstration of remote control, by radio, of a model submarine he had built for the First Electrical Exhibition in Madison Square Garden in 1898. The US Navy seriously dropped the ball on that one and didn't pursue it even though they were given first options. I agree - let's grow up and give credit where credit is due - the true story of radio and electrical pioneering in America deserves better than this rather transparent and mean-spirited ignoring of historic facts.

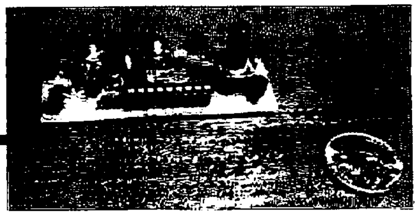
Les Hannibal, Fair Oaks CA. The Tesla article by John Wagener is something I am quite familiar with, since in the early twenties an old friend told of being back in Colorado when Tesla's high voltage equipment blew the power company's generators by the unanticipated RF feedback. He helped rewind those generators. In the 1890s General Electric, under the Westinghouse-Tesla patents, built an experimental set of AC generators which they installed at Folsom prison, where a prison-built dam diverted the flow of the American River. It had two Francis turbines using a 10-foot head of water to run the generators. At the same time G.E. built a power plant in Folsom city, a half mile down stream, using the discharge from the prison installation, but with an 80-foot head. The primary function of the Folsom prison generators were to try out the various multiphase circuits as well as generator and transformer efficiencies. Three-phase delta was found quite effective, so the larger plant in Folsom used the same circuity when it went into operation on July 13, 1895. A three-phase transmission line was installed from Folsom to Sacramento, some 20 miles, and went into operation that same summer of 1895. All of this occurred several months previous to the Niagra Falls plant which Wagener mentions. Knowing the difficulty experienced with leaky insulators on the transcontinental telegraph lines the bar-stool engineers in Sacramento predicted near universally that most of the juice would leak off the transmission line long before it reached Sacramento. Actually, the line loss was under 10%, though the soft copper wire was subject to continual stretching and breakage. But the major difficulty occurred in dry years when there was insufficient flow in the American River for continuous operation. Storage behind the dam was limited, so it was not unusual to see the generators start up every two or three hours and run until the water failed. Streetcars in Sacramento were often stranded. After the tests the Folsom Prison plant was taken over and operated by the prison near continually until 1954, when the Bureau of Reclamation built the Folsom Dam for flood protection and added power. Unfortunately the prison plant with its ancient control panels was dismantled, and Pacific Gas and Electric contemplated doing the same for the Folsom plant. At that time I wrote an S-O-S to Gernsback. He and several associates contacted Black, the president of P.G. & E. I don't know the details, but the Folsom plant has been preserved as a historical monument and is part of the state park system.

Back in 1925 one of my high school teachers asked a class in general science to name the individuals whom they thought had done the most for mankind by their scientific discoveries and inventions. I named Louis Pasteur and Lister in sanitation, and Tesla for polyphase power distribution and equipment. Few of the class had any concept concerning the part that AC power had accomplished in a scant 30 years. How many think to thank Tesla today? 73

73 Review

The Wilderness KC1

An integrated keyer-displayless frequency counter.



Jeff M. Gold AC4HF
1751 Dry Creek Road
Cookeville TN 38501

Who says you can't take it with you? I love to pack a small QRP transceiver, battery and necessary accessories and take to the trails. Two of my favorite pastimes are hiking and ham radio. The sum of the two is definitely greater than either of the parts. I often make on-the-spot decisions to pack up the goods and get going to one of the many beautiful parks that are not far from my home. Since it is quite easy to forget one or more of the necessary station accessories, I was quite intrigued when I saw Wilderness Radio's first station accessory offering.

"The keyer goes from seven to 50 wpm, and can emulate the two most popular iambic keying modes."

The KC1 is a combined keyer/counter based on a PIC 16C84 microprocessor. The unit is extremely small, .08" tall by 2.5" wide. Though the KC1 wasn't designed to be a replacement for the do-everything home-station keyer or digital frequency counter, it does have a number of very good uses.

This accessory was designed by Wayne Burdick N6KR to be inexpensive and to keep current drain low. To accomplish this, the frequency is reported to the nearest kHz in Morse code through the rig's AF amplifier without keying the rig. You just push a button on the panel anytime you want to know the frequency.

A really neat feature is frequency search. Say you have a schedule to meet someone on a given frequency. You can set the counter to that frequency and when you get to it the unit will alert you. The keyer/counter can store up to four VFO offsets. The KC1 will work with almost any direct conversion or superhet QRP transceiver, whether it's a single or multiband rig. There are only three controls for the unit: a speed pot for the keyer, a message play/record button, and a frequency read/search button.

The second major function of this accessory is as a memory keyer. The keyer goes from seven to 50 wpm, and can emulate the two most popular iambic keying modes. The memory part has variable length message buffers with a total of 50 characters of message memory. It also has a word-repeat macro to save memory. The sending weight and QSK delay are both user programmable and the keyer has an optional sidetone and a tune mode (for use while adjusting an antenna tuner). You can also use a straight key with this unit, though I prefer to be able to have both a straight key and paddles hooked to a unit. I love freedom of choice and sometimes change sending devices mid-QSO.

Assembly

The kit comes in a tiny sealed package and the parts count is very low. You can easily build and install this kit in part of an afternoon without rushing. The printed circuit board is clearly silk-screened and solder masked. One aspect of building this kit is that in order to get the size as small as it is, the parts on the board are densely packed. This should not present much of a problem if you have had any building experience, but you need to make sure that you get the parts on the board correctly on the first try. The board doesn't take kindly to desoldering efforts.

I found the directions very clear and encountered no problems at all in construction. The biggest problem I had was deciding which rig to put this cute little critter in. The instructions tell you how to install the unit in some of the more popular QRP transceiver kits. In addition, there are schematics and information you would need to install it in a kit that isn't listed.

Installation and Operation

With construction completed I finally had to see the little contraption work. It is so small with so few parts that I was bewildered at how it could possibly do all the things the manufacturer claimed. I had recently built a Wilderness Radio NorCal 40A QRP/CW transceiver. It has been one of my favorite rigs to operate and I love to take it portable. It runs for a whole weekend on a very tiny Gel Cell. The rig comes with termination points already available on the printed circuit board to attach the KC1.

The instructions have a template you can cut out to install the KC1 board on either the front or rear panel of the NorCal 40A. Being something of a klutz with a drill, and not wanting to mess up the beautiful blue case of this rig, I chose to install it on the rear panel. I made sure to really take my time and I drilled into a piece of wood so that I wouldn't bend the case. I did manage to do a very neat job and it only took a few minutes to install the KC1 on the back panel. After another few minutes of attaching all the wires from the KC1 board to the NorCal 40A printed circuit board, I was ready for the smoke test.

Smoke tests have always caused me some anxiety. In this case there was double anxiety: Not only was it possible to fry the new accessory, but it was also possible to burn up one of my favorite rigs. I powered up the rig and the KC1 immediately started to speak to me in Morse code, one of my favorite languages. I read through the manual and next entered the command mode of the

Facts and Fibs about Preamps

Two do-it-yourselfers.

Henry Falkner ZL1AAN
8 Kapai Road
Devonport
Auckland 9
New Zealand

When a satellite downlink barely makes it through the noise, one immediately thinks of using a preamplifier. I have built two samples each, one using a bipolar transistor (MRF901), and the other using an FET (BF981).

Both types have a switched bypass to allow transmitting. It's important that the switching works well. "I have 30 dead preamps sitting on a shelf. All had RF up their rear ends," noted friend and fellow ham Irvin Spackman ZL1MO.

Switching

I use a type of single relay that local radiotelephone manufacturers also use. Common lore has it that this is a no-no: you must use a relay at each end. Figs. 1 and 2 show that I have added shunt trimmers at the antenna and at the transmitter end of the relay. These are adjusted for maximum power on a power meter. There is no discernible difference in power between that arrangement and a direct piece of coax.

I have used this switching for both types of preamp, and there is no instability. The amplified output does not talk to the input from the antenna.

"Bipolar transistors have a higher noise figure than FETs," we hear. So they have. But if you use them with an omnidirectional antenna into an untuned front end, the received noise will mask the noise of the active device, even at VHF levels. Hence, having an improvement of 0.6 dB in noise reduction is not going to make an improvement in recovered signal. You start worrying about noise figures when you use a helical array into a cavity filter.

I used the MRF901 with resistor biasing only, with Pi- matching. I can't measure gain, but the S-meter on the FT-290 and TR9130 goes from 0 to 9 when the preamp is switched on.

"You cannot use Vero-board construction at VHF," is another objection. My preamps are dashed off on Vero-board. I did need to solder together all unused tracks and tie them to ground through the stand-offs. The signal paths were kept short, as in "dead bug" construction. On the first FET preamp I had the two tuning

> ***"The modern synthesized transceivers have untuned front ends. The mixer therefore has to discriminate from signals off the desired frequency."***

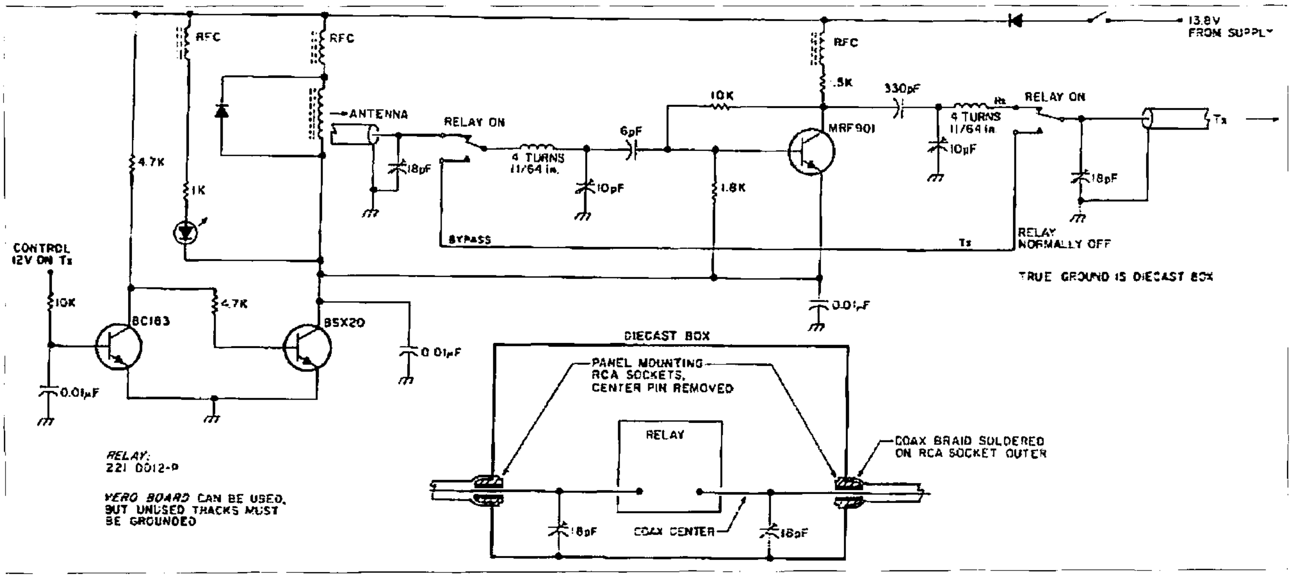

Fig. 1. A simple preamp that actually works.

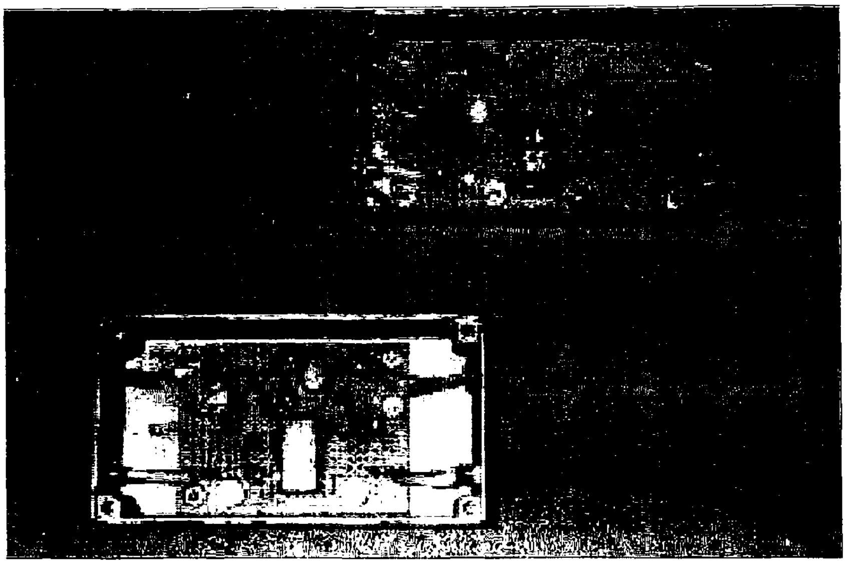

Photo A. A bipolar transistor preamplifier at the top (MRF901), and an FET preamp at the bottom (BF981). Both have the same RX-TX switching using a single relay and the die-cast box as the ground reference for the preamp. The box also is in the direct return path from the antenna.

coils too close together. The device became an oscillator. Screening between the two made no difference. The layout of the second FET preamp has the coils farther apart. Input and output signal paths are separated by grounded tracks, except within the relay. The preamp is stable, and the tuned circuits are non-critical.

Preamp Placement

"You must use preamps at the antenna feed point," say the Good Books. My feedlines are 25 feet of half-inch coax. The loss at 146 MHz is 0.7 dB for RG-8U. My preamps are a two-foot length of coax away from the transceiver. Power and transmit control voltage are brought out through the back of the linear amplifier of the FT-290ORII by a stereo lead and socket. The preamps have a stereo lead and plug, so they are removable. With a two-foot supply and control connection, the voltage drops are negligible.

I will allow that my first preamp had plenty of gain, but on FM there appeared to be no improvement in signal-to-noise ratio. The satellites did not open the squelch earlier with the preamp than they did without. It was a bipolar version, the board mounted on four metal stand-offs on the aluminum bottom cover of a plastic box. The box was lined internally with screening foil that touched the aluminum plate when closed. The braid from input and output coax was tied to the stand-offs.

Not Just a Container

I resolved to use a die-cast box, as shown in the photographs. I found panel-mounting RCA sockets, and removed the center contacts. I fed the coax centers through them and soldered the coax braid to the outer contacts of the RCA sockets. With the ground tracks of the PC board connected through metal stand-offs, the die-cast box was no longer merely a shell. It became the ground reference for the preamp and it substituted for the coax shielding in the return path from the antenna, without any discontinuity.

The resulting increase in signal over noise, together with a home-designed turnstile, allows me to decode ASCII from OSCAR-11 with as few as 50 errors over 10 kbytes, when the telemetry says the satellite is transmitting at 200 mW.

I built the FET preamp, with the same relay switching and the same boxing technique, because Irvin ZL1MO does not like

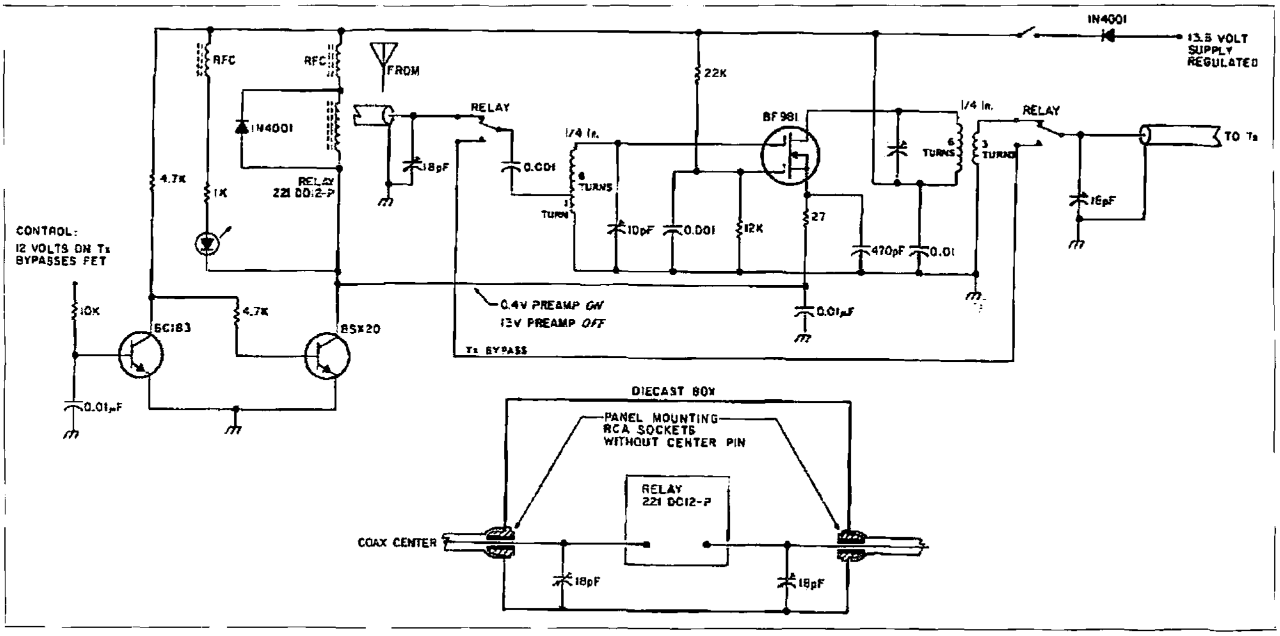

Fig. 2. The AMSAT-UK FET preamp with RX-TX switching added.

bipolar transistors with Pi-matching instead of tuned circuits. The FET version (BF981) does have a slight increase in gain, and improvement in signal-to-noise ratio. This is because tuned circuits do provide more rejection of out-of-band signals than Pi-matching does.

A Question of Gain

"You can't have too much gain," is another popular belief. Not true. The modern synthesized transceivers have untuned front ends. The mixer therefore has to discriminate from signals off the desired frequency. With more than 15 to 20 dB gain, your multimode rig will respond to the guy next door doing a bit of repeater-bashing, as well as to passing taxis and marine weather broadcasts. Handhelds convulse with any kind of preamp. My IC32AT even protests when I stick it on the slim Jim on the roof.

All being said, the two simple preamps described have become a useful addition to my shack. By taking into account what kind of antenna and transceiver they have to work with, and how the preamps are interfaced, I obtain results that compare well with what other amateurs achieve. Just yesterday a visiting British amateur, looking at an OSCAR-11 bulletin, remarked: "There's no error in it, is there?" 73

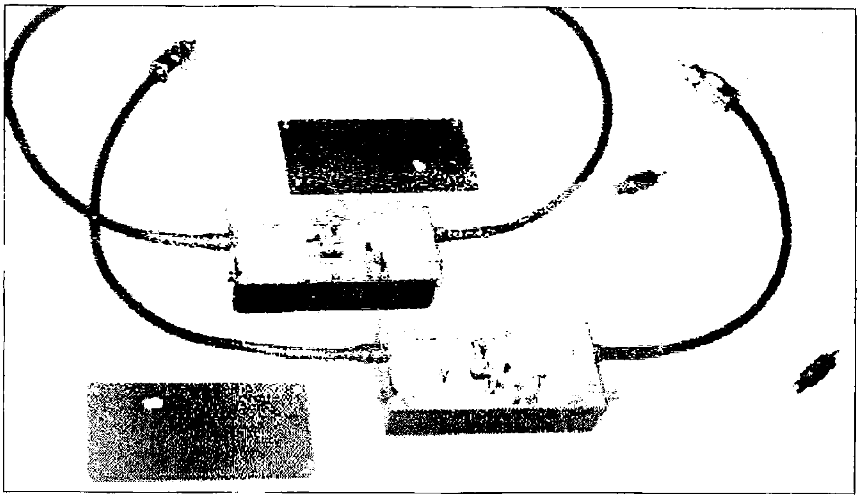

Photo B. These preamps can be used near the transmitter due to the boxing technique. Short stereo leads carry the power supply and the TX control voltage. With no voltage drop, the preamps and their switching work reliably.

NEVER SAY DIE

Continued from page 28

the Admiral in his office in the Pentagon. He was a short chap, so he had his desk up on a platform to add to his stature. Unless we published an apology immediately he'd see that no firm having any military contracts would ever advertise in the magazine.

We apologized.

Jim didn't get permission to use the ham station on the ship, but he did have a great trip to Antarctica and we got some good stories from it as he visited the Antarctic MARS stations.

Now cut to a couple years later, when I was the president of the Porsche Club of America and had an opportunity to visit the factory on a club-sponsored tour. I was happy with the Porsche Speedster I'd bought in 1957, so I arranged to pick up a new Porsche for a ham friend who couldn't get away for the trip. Our group of 150 flew over

The New Index Laboratories QRP Plus Transceiver

Check out this tiny, full-function QRP HF transceiver

Robert S. Capon WA3ULH
322 Burlage Circle
Chapel Hill NC 27514

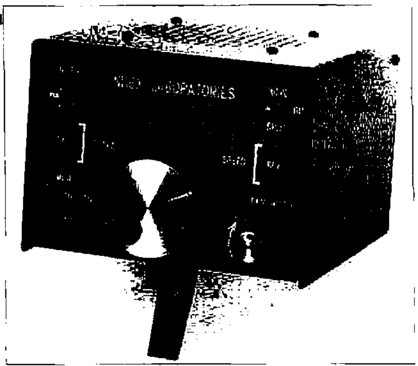
Index Laboratories has introduced a new version of its "QRP Plus" HF transceiver: an all-band, digital, 5-watt transceiver with many of the features usually found in full-sized transceivers. New features include a speech processor, improved AGC, and a significantly improved front end to the receiver.

The feature set is impressive:

- CW and SSB
- 10m - 160m
- Variable power output (0 - 5+ W)
- General coverage receiver (1.8 - 30 MHz)
- Variable bandwidth digital filter (100-2400 Hz)
- 20 memories
- Split frequency
- RIT/XIT
- Full QSK
- AGC
- Speech processor
- 2-function meter: S-meter, power meter
- Built-in keyer
- Current drain: 140 mA receive; 1.5 A transmit
- Dimensions: 5.5"w x 4.5"h x 6"d
- Weight: 5.0 lbs.

The major breakthrough is its exceptionally low current drain on receive, which is of critical importance for portable QRP operation, since the current drain determines the size battery you need. For example, most full-sized digital transceivers and miniature mobile HF rigs require 1-1.5A on receive. At this current drain you're using 24-36 amp-hours for 24 hours of operation, plus the added current drain when you're transmitting. These radios require a substantial sized marine battery or a generator for Field Day or for a weekend outing. For this reason, backpacking and bicycling aren't feasible with most commercial radios.

Index recognized the need for a full-function digital HF transceiver and designed the QRP Plus with low power drain as a central benefit in its design of the radio. It uses only 140 mA on receive! That's about 3 amp-hours for 24 hours. Thus, you can get through Field Day with a 6 amp-hour gel cell, even with a heavy-duty cycle of transmitting.



Getting Started

"Wow, is this a solidly built radio." The tiny steel cabinet fits neatly into my fishing tackle box, which I use for portable operation. It weighs in at five pounds; I had the feeling that I was holding a "radio brick." If you drop it on your foot, I'll bet on the radio.

It uses an SO-239 jack for the antenna, and a standard DC plug for the 12-volt input. It requires an accessory speaker-type microphone commonly used in VHF and UHF handie-talkies. Since there are no mounting holes or a mobile bracket, you will have to be resourceful to mount the rig in your automobile.

The radio's extremely small size required the combining of controls, making some functions of the radio not completely intuitive. For example, the keyer speed is displayed in words per minute by pressing both the Bandwidth and the Rev buttons at the same time. The main tuning knob adjusts the speed in 5 wpm increments. When the Bandwidth button is pressed the bandwidth is displayed, along with the SSB/CW display. To change modes you push the Fast button while holding in the Bandwidth button. The memory of frequencies is stored by pressing the Fast and Mem buttons simultaneously.

"Because of its exceptionally low current drain, this rig is a natural choice for backpacking, bicycle mobile, boating, taking on business or vacation trips, and of course, Field Day."

Most of the other functions of the radio *are* intuitive. For example, to change the bandwidth of the variable filter, you press the Bandwidth button and turn the main tuning knob. You press and hold the Fast button to tune quickly across the band. I quickly became accustomed to the radio, and found it to be easy to use. The built-in tilt stand is very handy for use in the field. Also, the tuning knob is very solid, and comes with a convenient dimple that makes it a pleasure to tune.

The power-efficient high contrast LCD display with large numbers is an excellent choice for use in sunlight. I tested the rig at night using only a single candle and was easily able to read the display. However, a small external

source of front lighting is needed to read the LCD display.

The radio automatically selects either LSB for the low bands or USB for the high bands, and you can't override the selection.

Operating Results

When using the radio I had the feeling that next year I can leave a lot of my favorite accessories at home because they're already built into this little radio. These built-in accessories include an power meter, electronic keyer, audio filter, and output attenuator.

I began putting the radio through its paces by checking its calibration against WWV, and against my big HF rig. The radio was in excellent calibration across all amateur bands, and on the WWV frequencies it was within 100 Hz. The receiver is on par with my full-sized HF transceiver. The AGC and the receiver front end showed significant improvement over the original version. It has excellent audio output to either a built-in 4-inch speaker or headphones. It's compatible with inexpensive *stereo* headphones rather than the harder to find *mono* headphones. I especially appreciated the variable bandwidth digital filter (100-2400 Hz in 100 Hz increments), which I wish I had on my full-sized HF rig.

I really appreciate having a general coverage receiver built into any amateur transceiver since I like to be able to listen to the news when I am out in the field or on a trip. The SSB sound is okay for news broadcasts, but for music an AM mode would help.

I fired up the transmitter and made some contacts. The QSK is very good, but is not the radio's strongest feature. I varied the power control on the back of the radio and found that the power output on 20 meters varied between zero and 7 watts, making the rig an excellent choice for QRPp work, especially as the solar cycle progresses and band conditions improve.

The original model delivered full power on CW, but had reduced power output on SSB, since it lacked a speech processor. The new model showed significant improvement in SSB power output.

My good friend Ernie AD4VA, who lives about two miles away and helps me test all of my ham radio projects, gave a critical listen to the CW signal and to the audio quality on phone. He couldn't distinguish between the CW signal of the QRP Plus and that of my full-sized transceiver. He also reported that it has very clear crisp audio on phone. Thumbs up.

I put the radio on the air to see what I could work running 5 watts into a run-of-the-mill tribander. I spent a few evenings working plenty of DX, including UA6HZ in European Russia, YQ9A in Romania, and SP9BRP in Poland who said: "Congrats on FB 5W QRP, Rob". On SSB I worked EA8BM in the Canary Islands, GIØAIJ from Northern Ireland and EA7AYD from Spain, who said: "Many congratulations with your 5 watts." EA8BM and GIØAIJ both gave me a signal report of 56.

The 20 memories, along with the fast slewing control, make it very easy to change bands. I set up the memories to the center of my favorite bands, and to WWV and the BBC.

Another nice feature is the radio's ability to toggle between the current memory frequency and the last frequency in the VFO, so you can quickly jump back to an interesting frequency. If used properly this feature is similar to having one band-stacking register, which can be very convenient.

Applications

Because of its exceptionally low current drain, this rig is a natural choice for backpacking, bicycle mobile, boating, taking on business or vacation trips, and of course, Field Day. It's also ideal for solar power applications. The radio can be operated at full break-even with a 5-10 watt solar panel charging on a sunny day.

Another application is as a second receiver to monitor the downlink during HF satellite operation on Russian satellite RS-12. In this mode, I uplink the signal using my base station, and monitor the downlink with the QRP Plus.

It can be used in the car, but the absence of a noise blanker is a problem. Even as a veteran QRP person, I find it challenging to work with a 12 dB power penalty combined with a 3 dB mobile antenna penalty. And the car is one place where I don't have to worry too much about current drain, because the car's electrical system can furnish all the current I need.

The Manufacturer

Index Labs is a small company new to the amateur radio business. When the QRP Plus first came out a year ago the company suffered from an inability to meet the demand. The company has matured during the past year and now maintains an inventory of radios so it is able to deliver from stock.

What's Missing?

Not much. A memory keyer would be a nice feature for QRP contests like Field Day. I predict that more and more commercial radios will include memory keyers as a standard feature. A noise blanker and an SWR function for the S-meter would be handy. Maybe on Version III next year?

The Wilderness KC1

Continued from page 40

KC1 and programmed in the offset. The numbers to send in Morse code to the KC1 were printed in the instruction manual so this only took a few seconds. I exited the command mode and pushed the frequency check button. To my great amazement it gave me the frequency. Not believing it right off the bat, I turned on my main station rig and tested the results across the NorCal's band. The little gadget was right on the money.

I next tested out the keyer memory functions. I found it very simple to program in a message and play it back. I used the NorCal 40A with the keyer in the ARRL Sweepstakes contest over the weekend and encountered no problems. As a matter of fact, I only had to repeat an exchange twice during the entire time I operated. This is quite good considering the length of the exchange in this contest and the fact that I was using 1.8 watts and a vertical antenna.

I was quite pleased building and operating this accessory and look forward to taking the rig hiking and camping.

The kit is offered in two versions. There is a complete kit which has the PCB and all board mounted components. You may still need to provide a few components, such as the key jack of your choice and a resistor or capacitor or two to match the accessory to your QRP kit. There is also a partial kit which includes the programmed microprocessor, 4 MHz crystal, all three transistors and the manual.

NEVER SAY DIE

Continued from page 43

on Lufthansa and were met by the Porsche people, who delivered our cars to us in front of nearby Solitude Castle. Then we got to drive them on the Solitude race track, which was closed to traffic so it formed a track about five miles around. Porsche had their top racing drivers there to teach us how to handle the cars at speed on the tight curves.

From there I drove to Paris, where the local hams had organized a party for me. And Admiral Bruton, who was now the head of American Expeditionary Forces in Europe, came to the party just to see me and we had a great time. All was forgiven. From there I drove to Geneva to meet the hams at 4U1ITU.

The ITU hams showed me all around the place and then filled me in on what was happening. It seems that the next major ITU meeting was next year (1959) and that they felt amateur radio was in serious trouble. Many countries were petitioning the ITU to cut the ham bands significantly, plus we had almost no support from the smaller countries of the world, where amateur radio was either unknown, or was an annoyance. To make it worse, when American hams visited these small countries they'd promise them anything to get a license and then would ignore their promises and violate their rules, running excess power and making phone patches. So amateur radio had left a bad taste with these countries.

These are the same small countries who'd been shafted by the previous ITU conference when the frequency allocations had been made. The big countries grabbed anything of any value, and left the small countries with the scraps. India was coming to the conference officially requesting that all ham bands be cut to 50 kHz, which was more than enough for their few hundred hams. Australia was officially requesting that our bands all be cut to 100 kHz. And not one country, including the US, was suggesting they be enlarged. What a terrible bargaining position!

But what about the ARRL, I asked? Sure, I'd had serious problems fighting the ARRL to get RTTY permitted below 2m. They had pulled every dirty trick they could to stop RTTY from being used on the HF bands, fearing that it was a threat to their CW traffic system. I knew how the chaps at the FCC hated the League for their arrogance, but I was unprepared for the anger and disgust the ITU people expressed.

They told me how Budlong, the ARRL General Manager for around 20 years, had represented the US at a previous conference and had had to be thrown out of meetings because he arrived drunk and brought local prostitutes with him. And all this, plus a sumptuous suite in the most expensive hotel in town, all unquestioningly paid for by the ARRL members.

This didn't really surprise me because, though I'd met Budlong many times at hamfests, I'd never seen him sober.

When I got back home I called Budlong offering, in light of the

Staten Island NY 10313-0006

A Vacation To Remember

One of the best perks of teaching ham radio classes is the fun of tracking the children's adventures once they're on their own with radio. One of last year's graduates that I took a particular interest in was Jesse Warren KB2VAK. Jesse was in my radio class at our school—Intermediate School 72 in Staten Island, New York.

Most of the 400+ students who come through the ham radio program each term find something in the curriculum that they can have fun with and relate to. Every once in a while, however, a student really distinguishes him- or herself with an exceptionally enthusiastic attitude towards ham radio. These are the students who give up lunch periods to come back to my room and sit in the "shack" to both listen and speak. I can spot that eagerness a mile away. They just can't get enough!

Jesse impressed me with his enthusiasm right from the beginning. His questions were always intelligent and thoughtful. He is definitely the kind of youngster who will contribute to and benefit from our hobby and service. While he was studying for his novice ticket in my class, he took my advice and "hooked" a parent into studying with him. Jesse's dad Richard enjoyed studying with his son, and was soon totally caught up in the wonderful world of ham radio. Richard is KB2VAM and has his General license.

As luck would have it, Jesse's family moved to Long Island, New York after he completed 7th grade. We stayed in touch via radio and phone. Last summer, Jesse very excitedly informed me that he and his family were planning a trip to Israel and Austria. I was delighted to learn that part of their preparations included trying to get reciprocal operating privileges in these countries. Unfortunately they weren't able to get operating privileges in Israel in time for the trip. Both Jesse and his father did, however, enjoy listening while they were there.

In Austria, Jesse had a big thrill when he spoke on a Vienna repeater to a ham in Slovakia. Can you imagine the enrichment the radio provided to a 13-year-old from New York? Not only did Jesse and his dad have a more exciting vacation because of their radio contacts, but so did the rest of the family. Younger brother Zach was totally intrigued by the excitement generated by the ham contacts. Mother, Barbara, who is a former colleague of mine, has resisted the urging to get her own license so far but enjoyed watching Jesse and his dad reaching out together for all these wonderful experiences.

"In Austria, Jesse had a big thrill when he spoke on a Vienna repeater to a ham in Slovakia."

During the six week trip, Jesse made contacts with many stations, and listened to many more. Some of the more memorable contacts were with stations in Vienna, Luxembourg and Slovakia. Some were on simplex and others were on repeaters.

Jesse offers the following advice: "Prior to leaving on a trip, it's important to apply for your reciprocal license well ahead of time. Leave a minimum of four weeks for processing. You may also have to list a local address on your application. Although I didn't receive my license in Israel because I hadn't allowed enough time, I did receive it in Austria because I was staying with my cousin and he received it at his local post office. I found it interesting to learn that Austrian regulations for radio are much stricter than in the United States. For example, you have to copy code at 20 words per minute without making a mistake. In addition, there is no third party traffic. Also, if you are caught listening to a ham radio without being licensed, you must pay a large fine. You must be 16 years old to get a license in Austria."

Jesse and his dad were pleased to learn that many hams in Israel and Austria spoke English. On the two Vienna repeaters 146.625 and 146.75 MHz, hams were eager to speak with them because of their American callsigns—KB2VAK/OE. When Jesse got home and contacted me, he told me he was very excited about increasing his code speed so that he could get more HF privileges by upgrading from Tech Plus to General and even higher.

I often wonder about the influence of ham radio classes on my former students, influences as varied as the children themselves. Each one finds his own particular niche and relevance. Many of the older children choose a particular course of study in college as a result of something they remembered that they liked in ham radio class. Others go the route of getting involved in community events such as walk-a-thons, parades, and other fund raisers. Some youngsters help provide communications during certain holidays with the REACT group in our area. Many, like Jesse, incorporate the radio into their daily lives. Events like family vacations become more fun and more meaningful to them because they're able to meet new friends in new places right from the palms of their hands. 73

Photo A. Jesse and Zach in Vienna under a statue of Johann Strauss.

A Stealth 40-10 Meter Antenna

An indoor antenna for the desperate that works from 40m through 10m.

J. Frank Brumbaugh KB4ZGC
Box 30
Salinas PR 00751-0030

A 40 meter dipole is approximately 66 feet long. Used with an antenna tuner it will do a fine job from 40 through 10 meters, an excellent selection of frequencies now that sunspots are once again decorating Old Sol. But for those unfortunate hams who live where space, zoning laws, deed restrictions or the regulations of Homeowners' Associations prevent the installation of outdoor antennas, there are a number of possible antennas which, while not as effective as outdoor antennas installed high and in the clear, will still produce a respectable number of QSOs.

Most of us are aware of such antennas: dipoles in the attic; flagpole antennas; fine gauge wire running out a window to a handy tree; mobile whip antennas; tuned high-Q loops; a weighted wire dropped out of an apartment window at night; rain gutters and downspouts; etc. Some work better than others. A few require good ground systems (often more of a problem than the antenna itself). However, balanced antennas do not require a ground, so let's go that route.

The part of the antenna that does most of the radiating is the high-current portion. In a dipole this is the wires on either side of the center feed point insulator. For a horizontal antenna this portion of the wire should be as horizontal as possible, and at the highest point above ground that you can manage. If there isn't sufficient space in a horizontal line for all of the antenna wire, and there won't be, the ends can be bent to fit the antenna into the available space. Since it's a balanced, center-fed antenna, a dipole does not require a ground system.

"It blends into the background so well your XYL won't even notice it!"

Of all the possible configurations of indoor antennas made of wire, the dipole in the attic is probably the best because it is as far above ground level as possible, and usually less of the ends must be bent to fit the space. However, if heating or air conditioning ducts run through the attic, they may absorb much of your RF, cutting your antenna off at the knees, so to speak. AC wiring running through the attic can also absorb your power.

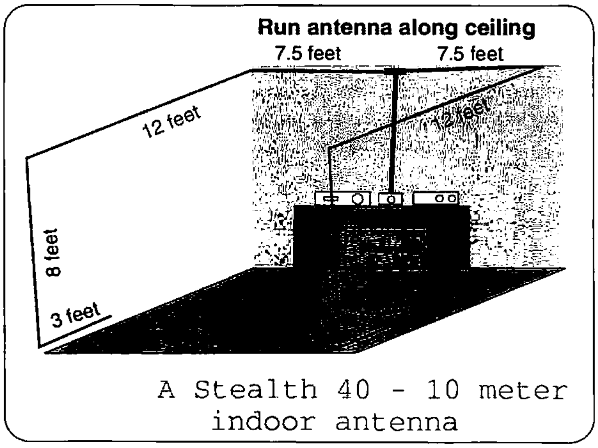

Fig. 1. Antenna installation diagram.

Another Dipole Option

For hams who don't have access to an attic, but do have one room at least 12 feet by 15 feet, with an (approximately) 8-foot ceiling, the 40 meter antenna I used will provide very good results from 40 through 10 meters when used with an antenna tuner. It also blends into the background so completely your friends may not even notice it!

Fully 39-feet of the radiating section of this 66-foot dipole are horizontal at the top of the room. See the drawing, which illustrates the entire installation. The insulator at the feed point is centered along the 15-foot outer wall, up against the ceiling. The center span is 15 feet long. From the ends of these points, where the wires meet the end walls, they turn 90 degrees and run along the tops of both 12-foot side walls, leaving approximately 11 feet of wire at each end. These wires are then dropped to the floor, and the remaining three feet at each end is bent along the baseboard in any direction. *Caution:* Be sure to tape the antenna ends with plastic tape so children or pets can't touch them accidentally and get an RF burn. The antenna ends develop high voltages when transmitting; keep them away from anything metal so you won't start smelling smoke.

Of course, insulated wire—ordinary hookup wire—should be used for this antenna. The insulation should match the

Number 52 on your Feedback card

The Hamtronics TD-4 Selective Calling Unit Kit

A tiny package of fun!

Larry Antonuk WB9RRT
Box 452
Marlborough NH 03455

In general, ham radio operators do just about everything with their radios. If a mode exists, there's a ham somewhere using it. However, one of the most interesting modes of radio operation also happens to be one that most hams know little about. That mode is the field of radio telemetry—the process of measuring and controlling values and processes via the radio waves. This mode is a little less understood than most, perhaps because the equipment necessary to implement it is fairly expensive and more complicated than simple voice gear. Also, the commercial market sources of used telemetry equipment are somewhat tighter than for voice radios, because less of this equipment is in use. So what does the ham who's interested in remote control do to learn more about this facet of ham radio?

The answer, as usual, is to build it yourself. An excellent product to start with is the Hamtronics TD-4 Selective Calling unit. The TD-4 provides a means to decode a four-digit DTMF tone, and use it for a single task. For the average ham, this represents the easiest way to perform a remote control operation. Since you probably already have a DTMF pad on one of your rigs the encode half of the system is set up. All you need is a receiver to hook the TD-4 up to, and you can use it to turn on or off anything, as long as you're within range of the radio. What you do with the output of the TD-4 is up to you—use it to open the garage door, turn on the lights, start the coffee, disable the local repeater, fire up the autopatch—it really doesn't matter. As Archimedes said, "Give me a relay closure and I'll move the earth." The hard part is getting that initial closure, but the TD-4 makes it easy and inexpensive.

Possible Uses

Before we get into how the TD-4 does its job, you may want to note that it's actually called a Selective Calling Unit. This controller was designed to mute a receiver speaker until a certain series of tones was received, at which point it would open the speaker and let the radio operator hear the message. That is identical to the operation of fire department pagers and monitor receivers, and can be used in the same way by hams. If you're tired of listening to chatter on the local repeater, just install the TD-4 on your base station. Give the four-digit code to your buddies, and have them call you by keying the repeater and dialing in your code. (Of course, you won't pick a code that will mess up the autopatch, and you need to know how to get the tones to pass through the repeater.) The Hamtronics unit will hear the code, decode it, and open your speaker. Carry on your conversation, and hit the "reset" when you're finished.

"All you need is a receiver to hook the TD-4 up to, and you can use it to turn on or off anything, as long as you're within range of the radio."

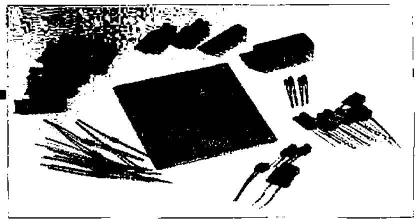

Photo A. The Hamtronics TD-4 board and components awaiting assembly.

A good application, but not very exciting. Why not install the TD-4 on your local repeater, and use it to detect "911" calls? If it hears one, have it start a tape recorder that will run until the patch drops, in order to record the call for training and liability purposes. (Does your state require the beep every 15 seconds?) How about a remote controller for that foxhunt transmitter? Turn it on or off as the hounds get closer. More diabolically, use the controller to raise and lower the power level.

The list of applications is limited only by your imagination. In any case, the controller will decode up to four DTMF tones in a sequence, and uses a set/reset latch arrangement. The first three tones of the *on* and the *off* sequences will be identical, and the last digit will determine whether the latch is set or reset. In other words, you can set up the decoder outputs to make a code of 123A to turn something on, and 123B to turn it off.

How It Works

So how does the TD-4 do it? All the circuitry is performed by four integrated circuits, with most of the work done by a G8870 DTMF decoder. This chip was originally designed for central office decoding applications, and takes care of all of the DTMF signal processing and decoding. It can accept a signal level from 100mV to 2V p-p, so no external audio signal conditioning is required. Valid DTMF tones are passed from the G8870 as hex digits to a one-of-16 decoder. Output lines from this decoder are jumpered to

a series of AND gates, which ensure that the tones are in the proper sequence. The final tone is used to "steer" the output of the prior AND gate to either the SET or RESET input of a simple latch. The output of this latch drives a single open-collector transistor, which controls the output of choice.

Kit Assembly and Documentation

The TD-4 is built on a high-quality glass epoxy double-sided circuit board, using plated-through holes. All jumper and input/output leads are marked on the board. The components are high quality, clearly marked, and easy to install. IC sockets are provided for all chips, making future troubleshooting a breeze. Due to the capabilities of the 8870 IC, the TD-4 decoder does a lot of work with just a few chips. This keeps the component count low, making it an ideal kit for the first-time builder. In addition, the circuit is so straightforward that even an inexperienced troubleshooter should be able to locate and correct any wiring problems.

The Hamtronics documentation is refreshing. The schematic and parts layout diagram are well done, and simple to follow. The instructions are clear, but assume that you've got a little intelligence. You won't find any of that "Insert left end of R1. Now insert right end of R1." stuff in this manual. As a matter of fact, the manual is nine pages long, and the entire construction section takes up about one-third of one page. So what's on all the other pages?

Well, useful stuff. Information on how to test the thing once you've built it. An explicit section on how to set the jumpers to program different codes. How to hook the decoder up to your radio. How to drive a relay, without blowing up the output transistor. Detailed selective calling applications. A serious troubleshooting section. And best of all, modifications. Not too many kit manufacturers give you the information you need to start hacking right off the bat (OK, so they call it *customizing*). They even give detailed instructions on how to convert the TD-4 into a "LiTZ" (long tone zero) decoder, for use on the nationwide repeater emergency

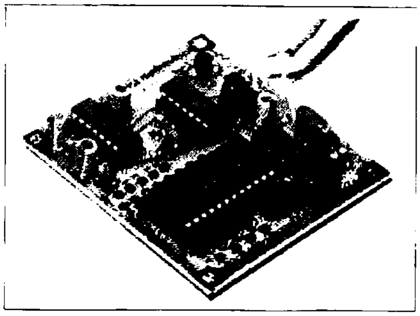

Photo B. The completed TD-4 board, just prior to installation of the programming jumpers.

system. In any event, the manual for the TD-4, while somewhat lacking in photos and drawings, treats the builder as if he or she knows something about electronics, and wants to learn more. More manuals should be like this one.

While Hamtronics gives the builder information on how to modify time sequences, etc., they don't get into any serious hacks, and the TD-4 is just asking for some. If you don't need the single function on/off arrangement provided, a couple of relocated jumper wires will allow the controller to provide pulses to two separate devices, allowing you to pulse on either of two timed functions. Need more functions? Hamtronics doesn't give you any more room on their circuit board, but considering that additional AND gates go for about 50 cents, why not add on an auxiliary board to give you a few more options? By duplicating the existing AND gate circuitry on another PC board you can control as many functions as desired. (Why not set up that foxhunt transmitter for on/off, high/low power, and even flip the frequency 5 kHz in either direction? *That* should keep 'em on their toes.)

As we said, the Hamtronics TD-4 is a great way to get into remote control with a single function, but it also provides a neat base for future expansion. Remote control applications haven't been fully explored by most hams, but equipment like the Hamtronics TD-4 makes experimentation easy. Compatible with gear that most hams already have, the TD-4 is a good entry-level project for the beginning remote control enthusiast.

"The circuit is so straightforward that even an inexperienced troubleshooter should be able to locate and correct any wiring problems."

HAMSATS

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

AMSAT's (the Radio Amateur Satellite Corporation) newest and most complex satellite, Phase 3-D, is scheduled for launch later this year. Check out the article "Into Orbit With the Final Phase 3 Satellite" in this issue. Even with a few schedule slips, the event is less than a year away. In preparation, this month starts a series of columns for the newcomer to this fascinating segment of the amateur radio hobby. It will take time, information and energy to get ready for Phase 3-D, but there are several easy steps that can get a potential enthusiast on line with the OSCAR (Orbiting Satellite Carrying Amateur Radio) program.

Getting Started

You may already have everything you need to join in the fun on the amateur-radio satellites. It is a common misconception that satellite chasing is expensive and only for the technically elite. Even if your only "rig" is a 2 meter handie-talkie or a shortwave receiver, there are signals from space that you can monitor right now.

If you have a computer (most hams do these days) the chore of knowing when to listen for an OSCAR becomes a simple task. Many programs are available to find and track the satellites.

If your only antennas are attic dipoles or omni-VHF types, it's easier than you think to get involved. Some hams have only mobile and portable systems for their hamsat pursuits and still do remarkably well.

Finding detailed information about the ham satellites used to be a significant chore. Today that's not the case. Many books and articles have been written covering the myriad facets of satellite work. Some may be found at well-stocked bookstores or ham radio distributors, while others are only a phone call away.

2 Meter Downlinks

Satellites that provide 2 meter FM downlinks are very easy to copy with only a handie-talkie and an omni-directional antenna. Although the typical "duckie" antenna will work, one that has at least zero-dB gain (a quarter-wave whip) is better. Set the frequency of the HT or other 2 meter receiver (a scanner will do) to 145.825 MHz. Two satellites, U-O-11 and D-O-17, use this downlink frequency for their telemetry and digital message outputs.

UoSAT-OSCAR-11 was launched in March 1984. Built by the University of Surrey in England and launched by NASA from the Western Test Range in Lompoc, California, it is still operational today, sending 1200 baud ASCII data using Bell-202 compatible tones. The power output is only 400 milliwatts, but from a polar orbit of 680 km, this low-power signal can be heard with ease when the satellite is above the horizon. For most locations, four to six passes per day (about 10 to 18 minutes each) can be monitored. The satellite is also capable of limited digital speech using a National Semiconductor Digitalker chip set. Short messages are occasionally programmed by the ground-control station in Surrey.

DOVE-OSCAR-17 was sponsored by AMSAT-Brazil, but was designed and constructed by AMSAT North America (AMSAT-NA). Launch was on an Ariane 4 from Kourou, French Guiana, in February 1990. DOVE is an acronym for Digital Orbiting Voice Encoder. Although it is capable of complex voice synthesis, it normally transmits packet telemetry at 1200 baud with up to 4 watts of output power. A standard packet-radio TNC (Terminal Node Controller) can be used to view the messages and telemetry from D-O-17. The polar orbit is slightly higher than U-O-11, at 800 km, and can also be heard between four and six times per day.

Another source of signals from space comes from the Russian *MIR* space station. Many ham radio experiments are being tested from *MIR*, but the most popular activities include voice contacts with the cosmonauts and packet operation from the on-board PMS (Personal Message System). Voice and even SSTV (Slow-Scan TeleVision) can be heard on 145.550 or 145.800 MHz. Packet operation is typically on 145.55 MHz. RØMIR is the most common callsign sent from MIR.

10 Meter Downlinks

The two most popular satellites with 10 meter downlinks include RS-10, launched in June 1987, and RS-12, launched a few years later. The signals from these Russian hamsats are not FM. They transmit CW telemetry and act as communications transponders for CW and SSB signals. The satellites are controlled by RS3A in Moscow and are in polar orbits at about 1,000 km altitude. Even though power output is only 1 watt, both can be heard on a typical shortwave receiver with a simple dipole.

RS-10 transmits its telemetry on 29.357 MHz. The transponder downlink range is from 29.360 to 29.400 MHz. During a typical 10- to 20-minute pass, CW and SSB conversations can be monitored in the 40-kHz wide transponder passband. The stations heard are sending their signals to the satellite on 2 meters. The uplink passband goes from 145.860 to 145.900 MHz. Most RS-10 users only need about 25 watts to an omnidirectional base antenna to get into the satellite.

RS-12 telemetry can be heard on 29.407 MHz. The transponder downlink range extends from 29.410 to 29.450 MHz. The uplink, however, is on 15 meters from 21.210 to 21.250 MHz. While many stations using RS-12 employ newer 100 watt transceivers that can transmit on one band (15 meters) and then receive on another (10 meters), it's not uncommon to find QRP (low power) stations employing very simple transmitters running only a few watts on the uplink and inexpensive 10 meter rigs on the downlink. Dipoles in the attic on both the uplink and downlink bands will work with RS-12.

Tracking

While it is possible to set up a receiver and wait for a satellite to come by, it can be frustrating. The easiest way to find the hamsats noted above is to use a computer and a good satellite tracking program. Many programs can be found on BBSs (telephone Bulletin Board Systems) or via the Internet (ftp.amsat.org or http://www.amsat.org) as shareware or freeware that will perform the basic function of providing dates and times of the passes over a specific ground location. There are also companies and organizations like AMSAT-NA that sell software packages for most popular personal computers. Some programs provide real-time maps and coverage projections in addition to tabular time and antenna-pointing information.

Information Sources

Columns and articles dealing with hamsats have appeared in all the major ham-radio magazines since OSCAR-1 was launched in 1961, but for the newcomer, some good reference books provide more perspective. The suggested titles below can be purchased through AMSAT-NA. Write to AMSAT at 850 Sligo Avenue, Suite 600, Silver Spring MD 20910-4703, or call (301) 589-6062 to get the latest prices and information about membership and other publications.

1. *The Satellite Experimenter's Handbook*, 2nd Edition (1990; ARRL, 350 pages) by Martin Davidoff K2UBC.

2. *How to Use the Amateur Radio Satellites*, 5th Edition (1995; AMSAT, 32 pages) by Keith Baker KB1SF.

3. *The RS Satellites Operating Guide* (RS-10/11; RS-12/13 and RS-15), (1995; AMSAT, 30 pages) by G. Gould Smith WA4SXM.

This month was an overview. Next time, and in the months to follow, specific topics about the high-orbit satellites, rigs, antennas, coax, Doppler shift, Faraday rotation, the digisats, and many more facets of the hamsat chase will be investigated.

A Stealth 40-10

Stevenson MD 21153

I love gadgets. I'm not afraid to admit that. After all, in this crazy hobby of ours it's an affliction that insinuates itself into our very fiber. This month, let me tell you about a new toy that can breathe new life into many forms of digital communication.

For a tad under two hundred dollars, I got the "Snappy Video Snapshot" from Play, Inc. For that money, you get the digitizer itself, a battery, cable, and three software packages. One of those runs the unit, but the other two are nifty graphics manipulation packages; more about them later.

Physically, the Snappy device looks like a fat candy bar with a DB-25 plug on one end. It plugs into the parallel port on your PC compatible computer, which needs to be at least a 386 running some flavor of Windows©, with 4 Mb of RAM and 4 Mb of free space on the hard drive. Video may be supplied "live" from the video output jack of almost any camcorder or VCR.

Once you load the software, you are able to "snap" a picture from moving video, or take a longer exposure, with higher resolution, from still video. The results are truly amazing. Photo 1 is a picture of the Snappy unit, taken with my VHS camcorder and digitized. The picture was then saved as a TIFF file, sent to 73 electronically, where it was placed onto this page. Neat, huh?

As I said, the source can be a live camera or VCR, and the "shutter" speed can be set to stop a moving video, or progressively longer exposure for higher quality with non-moving images. Image size may be scaled at 320x240, 640x480, which is full screen VGA size, or an astonishingly beautiful 1500x1125, all saved as 24 bit true color files, even on a monochrome machine. That last option does take up a bit more disk space, of course.

Now, if just snapping video is not enough for you, the two packages which accompany the digitizer are really something. For me, the more useful of these is Fauve Matisse, a graphics manipulation and drawing package which allows the creation, editing, and alteration of images from the Snappy Video Snapshot, along with other sources. It accepts and saves images in most of the popular formats, such as JPG, BMP, EPS, GIF, PCX, TGA, and a few others. You can retouch photos, produce comic shots with switched heads, or use the tools to paint pretty pictures, as my nine-year-old does.

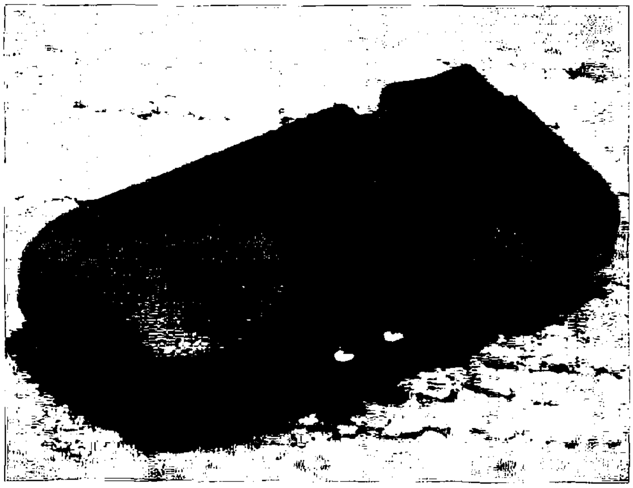

Photo 1. Pretty neat, huh?

The other program, not as useful to me but you might like it, is Gryphon Morph, one of the classic programs used to "morph" or change one picture into another. Starting with one photograph, key points are identified and corresponded to points on another photograph. The program then generates intermediate images which effectively change one into the other. The results can be astounding and fun to watch.

For the money, this is really a neat way to generate the digital images that are becoming necessary in electronic communications. While you may be inclined to get a scanner, they are typically more expensive, and can only copy flat objects. With the Snappy you can digitize your kids! Now, to be honest, there are a few glitches. Because it uses your parallel port, you cannot print with the Snappy installed unless you have two parallel ports or print to a serial port or network printer. I use an A/B switch to select the Snappy or my printer. The quality is good, but a 1200 dpi scan of an 8x10 photo on a thousand dollar scanner may be better, albeit for more money and a slot on your motherboard for the interface card. As the saying goes, "You pays yer money and takes yer choice."

To help you decide if the Snappy will fill the bill, Play, Inc., has a web site at: http://www.play.com where you can read a bit more and download a slide show of Snappy images. You will need a SVGA screen for the demo, but it is worth a look. Let me know what you think. If you get a Snappy, use it to take pictures of yourself and station, and send them to me by E-mail. Who knows? You might just see yourself here in RTTY Loop!

As long as I'm on the subject of "high tech," this month's web find addresses the cutting edge of packet communications. Mike Curtis WD6EHR, has placed a "9600 Baud Packet Handbook" at: http://inss1.etec.uni-karlsruhe.de/~df0uk/96man2.txt. This handbook for K9NG protocol 9600 baud packet addresses the questions raised by those inclined to exceed the 1200 baud speed barrier, without wanting to hear "But Cap'n, it canna go that fast without breaking up!" Take a look, it's an interesting work.

As I write this month's column, last month's column announcing the RTTY Loop Home Page, at: http://www2.ari.net/ajr/rtty/ has yet to be printed, and yet we are averaging about a dozen or so hits a day. I don't know where these folks are finding out about the page, but I anticipate the count will be much higher by the time this column sees printer's ink. On the home page, I have several past columns, with current ones as well, a full listing of the RTTY Loop Software collection, interesting ham radio related links, along with a few other strange sites, and a few things for direct download. Take a look, tell your friends, and drop me a line.

For those not online, the full listing of the RTTY Loop Software Collection may be yours for a self-addressed stamped envelope, sent to the address at the top of the column. E-mail may be sent to me via the Internet, at: ajr@ari.net; on America Online at: MarcWA3AJR; or on CompuServe at: 75036,2501; although that may be a bit simpler as well by the time this is published.

I'm accumulating quite a few cards and letters from some of you, with which to fill the April basket. Don't miss next month's column, when I shower you with answers.

NEVER SAY DIE

Ham to Ham

Special Six-Month Anniversary Column

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

"Ham To Ham" is in its sixth month of life within the pages of *73 Amateur Radio Today* and the tips, suggestions and ideas keep coming in...good ones, at that. Uncle Wayne and I had originally given the column six months to get off the ground, to see if it's what the readers want, and we've made it! Please keep the ideas flowing this way. It's your column; I'm acting as intermediary, putting all the ideas into one place and editing the text for uniformity, but it's an open forum for everyone to share. In celebration of the six-month mark, the column is a bit longer this time, to give you more of the information you've said you want, and as a "thank you" to the many who've sent in contributions. Thanks also to Uncle Wayne Green for providing the forum.

By now you are able to see the direction that the column is taking, so you'll know pretty much what we're looking for. But even if you'd like to see it take a somewhat different avenue, send me your favorite tip and let me know what direction you feel the column should be moving...I'll try to keep an open ear for any serious suggestions for improvements.

Poor Solder Joints

I've personally run into a number of poor solder joints in well-known commercially-made ham gear, and I know others have, too. The solution in all of these cases was to reheat, and perhaps rewet, the offending connection. Rewetting a solder connection is just another way of saying "put a bit of new solder on it as the connection is reheated." If the connection looks mottled (marked with spots) or lumpy and dull, then removing the old solder with wicking-braid or a "solder-sipper," and applying all new 60-40 solder to the connection is the answer.

Just because a radio "came that way from the factory" doesn't mean that it was made perfectly. Here's part of the reason: between any two copper connections, such as the copper foil pad on a PC board and a copper wire or component lead attached to a board by a solder connection, there are: 1) the copper foil pad, 2) an alloy layer, 3) the solder mass itself, 4) an alloy layer, and 5) the copper component lead or wire. This is true of every good solder joint. If something happens to prevent that alloy layer from forming at either copper junction, or if it degrades with time, then a high-resistance or intermittent solder connection is the result.

One cause of a defective alloy layer is movement during the "plastic" phase of the solder cooling process ("plastic" meaning capable of being altered or changed). As solder goes through the liquid (melted) state to the solid (hard) state, in all but one solder formulation there is also a plastic-state temperature range. The length of time of the plastic state will vary with the respective amounts of tin and lead in the solder you're using or reheating. As an example, at the extreme end of the formulation scale there is 90-10 solder, 90% tin and 10% lead. 90-10 has a 700°F plastic range, between approximately 4300°F and 3600°F. Any movement of either of the pieces being soldered during that cooling range will result in a poor solder joint.

At the other extreme is 10-90, 10% tin and 90% lead. Its plastic state is from about 5800°F to 4400°F, or 1400°F of cool-down range, when the solder is still plastic. Movement anytime during this plastic state results in what's commonly called a cold solder joint. Insufficient heat at the joining of the two copper pieces during soldering can cause the same condition. To make a good connection, the solder must go far enough into the liquid range, drop down through the "plastic" range, and then enter the solid range without movement. And those two good alloy layers must exist for the lowest-resistance electrical connection to exist. If more than two wires or component leads meet then a good alloy layer must exist between each and the rest of the solder mass forming the connection.

Most of us use 60-40 solder, 60% tin/40% lead, because it has the best "wetting" characteristics. That also helps to provide a good alloy layer. 60-40 only has a 90°F or so plastic state, from 3700°F to 3610°F, so it's also helpful from that standpoint. There is a 63-37 solder formulation, 63% tin/37% lead, that has virtually no plastic state. It's called eutectic solder because the liquid-to-solid state is direct; that's the eutectic point. But that's the *only* formulation that skips over the plastic state.

Another reason why the alloy layer may not form properly is oxidation on either of the two copper parts, or some foreign substance on the parts that doesn't allow proper wetting and flowing of the solder. That's the prime reason why parts should be bright and clean-looking, and why only solders containing rosin flux should be used on electrical connections. The rosin flux, in the solder, or applied externally via soldering paste or liquids, is not a part of the connection itself. It "floats" the surface oxides from the two copper pieces and holds those impurities in suspension until the joint is alloyed. Remnants can then be cleaned away with a flux remover.

So why would a factory-made rig have poor solder joints? Perhaps the parts weren't clean enough when assembled onto the boards, or the board itself was contaminated. Perhaps there was some movement of the parts during the plastic stage of the cool-down period, perhaps not enough heat penetrated to the two copper connecting metals, perhaps the flux used wasn't doing its job, perhaps the solder formulation was off-specifications...any of these situations is possible. The issue is less "why" and more "where," since finding and fixing the poor connection(s) is the job at hand. Knowing why the factory-made connection failed is more academic than pragmatic once a piece of equipment is in our hands.

There are a couple of other caveats in soldering, though admittedly one may not run into them often. The first concerns a connection's heating as large amounts of current pass through it. All solder joints have some amount of finite resistance, but it becomes important when a connection must handle higher currents, such as in a high-power linear's plate tank circuit; the solder connection can actually soften or melt if special precautions aren't taken. A higher melting point solder would be a 5-93.5-1.5 formulation: 5% tin, 93.5% lead, and 1.5% silver. This formulation raises the solder's melting point to about 6000°F. Another special situation exists when soldering silver-plated components. To prevent the silver-plating itself from migrating, a high silver formulation solder can help. 96-4, which is 96% tin and 4% silver (no lead), will prolong the "wetting" time before silver migration takes place. It requires a higher melting temperature, about 4300°F, but provides a stronger connection. Radio Shack™ carries this under their part number 64-025.

Easy Backyard Coax Cable Protection

From Ken Guge K9KPM of Lombard, Illinois: With spring not too far away, here's an easy-to-implement tip for protecting a surface backyard coax cable from pedestrian damage and lawn-mowing hazards:

"When I originally installed my 40-meter horizontal wire dipole antenna in my backyard, the center-feed coaxial cable ran down the trunk of a large tree, across the grass to the house, and then through a small hole in the above-ground portion of the basement wall. Wanting to protect the coax from people walking on it, as well as from other yard activities, I made a simple three-sided wooden cover to lay over the top of the cable. It worked for a while, but keeping the wooden cover looking good with paint and, more importantly, keeping it from rotting underneath, became a too-often-avoided task!

"While browsing through an office supply store one day, I spied the cable protection strip material used in many offices to hide across-the-floor cabling, and I immediately visualized it protecting my backyard above-ground coax instead. One brand goes by the name SL Waber Cordgard®, and is usually available in 6-ft. or 15-ft. sections. It's a rugged vinyl casing that covers the entire cable, and has a curved top surface that helps to prevent tripping, if someone doesn't happen to notice it running across my yard! Just as important, it requires absolutely no maintenance and should last for a number of years, even outdoors, before a replacement might be needed. It's a big improvement over the wooden cover that I was using before, from the standpoints of protection for the coax, pedestrian safety and appearance."

Good application, Ken. The same type of product could, of course, be used in the ham shack itself, if a cable or two are needed on the opposite side of the room from your ham station operating position, providing the same protection and safety Ken has found it does outdoors. It could also be run up a wall if a cable "drop," either indoors or out, needs to be hidden.

Extending the Fun

From Mike NØALJ of Rogers, Arkansas: Wire yourself into your hobby without having to stay in the shack.

"Here's an idea I've used to enable me to enjoy my various radios in places other than my ham shack. I've set up a speaker in the garage so that I can listen to my favorite ham bands while I'm working on my HO train layout there. I've also extended a speaker out to the patio deck, so that I don't miss anything when relaxing in the open air or working around the yard. I've also found that in the ham shack itself a local extension speaker there can enhance the sound significantly.

Sure Seal for Outdoor Connectors

From Bill Thim N1QVQ of Broad Brook, Connecticut, try this tip for permanently sealing outdoor connections, such as those that might be used for coax, power, control cabling, etc.:

"I recently had some work to do on my well and came across a power cable splicing scheme that could also be useful with coax and other types of cabling used for outdoor ham antenna work. Some home improvement centers (Home Depot, in this case) sell a splicing kit for submersible pumps that is truly watertight when used as directed. After the splice is made electrically sound, the connection point is coated with a silicon-type sealant, then a six-inch-long section of heat-shrink tubing is carefully slid up the cable to cover the joint and sealant. When the tubing is shrunk with a small torch or heat gun, until the sealant can be seen oozing from both ends, you'll have a connection that defies the worst of the elements. The tubing supplied with the kit is large enough in diameter to fit over a PL-259 or SO-239, so it's just the ticket for ham antenna use as well. Once the process is completed, you'll have to cut the connection apart if you ever want to get into it again, because it is meant to be completely permanent!"

Good find, Bill. Read the cautions on the label before using any silicone-type of sealant on antenna and other connectors, though. Some sealants warn against their use directly on certain metals (in many cases, brass and copper). Perhaps wrapping the connection first with electrical tape, or a thin application of a flexible coax-seal product, to avoid direct contact with the metal, would offer enough protection to avoid the corrosive effects of some of these silicone-based sealants. Furthermore, if you are unable to locate the kit Bill mentioned, you might be able to purchase the essential parts separately. It's a worthwhile process to remember next time you need to waterproof antenna connections. Fast-setting epoxy might work in place of the silicone adhesive, but it wouldn't have any flexibility when cured, and epoxy often cracks if subjected to mechanical strain.

An Emergency 12-Volt DC Power Distribution System

From Erling Gruel WB9OJD of Fond du Lac, Wisconsin: Looking for a nice layout for an uninterruptable, emergency 12 Volt DC Power system?

"Here's an idea that's reasonably easy to duplicate for those who don't have a gas- or diesel-powered generator to allow them to stay on the air during power outages. Emergency preparedness has been a long-standing traditional part of the amateur radio credo, and this solution is economical, straightforward and, I've found, very functional.

"I was mainly looking for a means of powering my 50-watt, 2 meter solid-state transceiver, a couple of scanners, simplex autopatch, CB radio, some limited lighting and an elapsed-time 12 volt DC automobile clock (or an interval timer/clock such as the Radio Shack™ #63-884) so that I know how long the emergency backup system has been running. Some of the newer 12 volt DC HF radios could also be powered from this setup if transmissions are kept brief or minimum power is used.

"The heart of my system is a wooden box, attached to the shack wall near my operating desk, approximately 8" high by 7" deep by 12" wide, that contains all the necessary metering, toggle switches, fuse holders and a four-pole, double-throw relay whose 12 volt coil is normally held up by an AC mains-powered 12 volt DC power supply. However, when the power fails, the relay drops and transfers everything normally powered by the station's 12 volt DC supply to the 12 volt DC backup system instead. A master cutoff switch disconnects the emergency backup battery if the relay de-energizes for some other reason, or if I turn off the main 12 volt DC station supply. The emergency backup battery is kept charged by a continual constant-voltage trickle charger during the norm, when commercial power is available.

"I've also extended the battery supply leg of the system into my garage so that if the ham shack backup battery runs down I can quickly and conveniently utilize my car's battery to keep the equipment going! The car, of course, can be started and backed out of the garage ahead of time, so that it will supply charging current to its battery, giving me virtually endless power....at least until the car runs itself dry!

"From the garage to the basement ham shack, I used heavy Romex cable to keep the losses as low as possible, and I've terminated the cable in steel electrical boxes at each end, clearly marked as being 12 volt DC only. I have a cord and connector coming directly from my automobile's battery to the front grill, and an extension of this cable to get from the car's front grill over to the garage wall feed box. Whatever type of connectors you decide to use to implement the system, they should not be easily mistaken for any other purpose and should be husky enough to carry the current that you anticipate your particular system will draw under maximum usage.

"I found that a marine type of deep-cycle lead-acid battery works best for the basement backup battery. Not including the battery, the whole system cost me under $100 to implement...not a bad price for the extra sense of operating security that it provides. The drawing in Fig. 2 pretty well shows my own particular setup, but I'll be happy to answer any specific questions from *73* readers as best I can."

A 12 volt DC to 120 volt AC inverter could also be included in your system for powering 120 volt AC only equipment but, of course, that would up the final cost. Also keep in mind that in any system like this, everything should be made easily and quickly disconnected, clearly marked and neatly installed, so that in an emergency you'll waste as little time as possible having to figure things out! We all tend to forget the details if a system isn't frequently used. Making a diagram of the entire system, and posting it in both the shack and the garage, would be time well spent. Erling also mentioned that he's willing to supply more information to any reader having a sincere desire to duplicate his idea. It's nice when contributors are willing to help others in similar situations, so please be polite and appreciative of the free assistance...and always include an SASE (self-addressed stamped envelope) for a reply.

Editor's note: if you would like a wiring diagram of the Emergency 12-Volt DC Power Distribution System, please send a large business size SASE to "Wiring Diagram," c/o 73 Magazine, 70 Rte. 202 North, Peterborough NH 03458.

Editor's note: ***if you would like a wiring diagram of the Emergency 12-Volt DC Power Distribution System, please send a large business size SASE to "Wiring Diagram," c/o 73 Magazine, 70 Rte. 202 North, Peterborough NH 03458.***

SCR Testing Idea

From Herb Foster AD4UA of Melbourne, Florida: A suggestion for a simple method of SCR testing.

"In my experience working on RCA television receivers on a part-time basis, I've come across an easy way to determine the proper operation of any suspected silicon-controlled rectifiers in the circuit. It isn't hi-tech but it's worked for me every time! All you'll need to duplicate this method is a source of 12 to 20 volts DC, a digital multimeter, and a 470 ohm 1/2 watt resistor. If the SCR happens to have a PIV rating of less than 12 volts DC, use that lower voltage, but most will not be harmed by the 12 to 20 range specified.

"Completely remove the SCR from its circuit, connect the 470-ohm resistor in series with the device's anode lead, then to the DC power source. The sample diagram in Fig. 1 shows the test circuit schematically. Connect the cathode of the SCR to the minus of the power source. Clipping the digital multimeter across the resistor, with the power source tuned on, there should be no voltage drop across the resistor because the SCR should not be conducting (or leaking). Now connect the gate of the SCR to the anode just momentarily. The meter should read a 1- to 3-volt DC drop across the resistor if the SCR is conducting normally. Momentarily disconnecting the SCR's anode from the source voltage should again cause the device to stop conducting.

"This simple test effectively checks the SCR for opens, shorts, leakage, and the ability to fire normally and latch up, then return to its static state when the anode is momentarily opened...all you'll need to know about it. If it passes this test, then without question, it's good."

Herb has submitted a couple of good ideas to this column. Here's

More Century 21

Remember where we left off last month?

Inside the power amplifier of the Century 21 you'll find four active devices: two drivers and a pair of final transistors. Looking inside the PA compartment of my unit, it became quite clear to me that I was not the first person to visit. It seemed that at one time, or more, the two final transistors had been replaced. In fact, the solder pads for one device had been lifted from the Fiberglas board.

The two final transistors are MRF475s. They are available from Ten-Tec for about $5 each. I'm sure you could get the replacement parts from Digi-Key or Mouser; both stock the NTE replacement series. I don't have a recent copy of the NTE replacement guide, so I don't know the proper NTE replacement number.

Both final transistors are insulated from the heat sink by a mica insulator and hardware. If you have to remove one of the finals, don't lose the hardware; you'll need it when installing the new devices.

Repair Work

Since I had no idea which one of the finals produced all the smoke, I decided to order a pair and install them both. To remove the final transistors from the Century 21, start by removing the hardware securing the device to the heat sink.

Now, carefully unsolder the wires from the larger transformer and bend them out of the way. You have to do this so you can gain access to the transistors. There are two 2 watt resistors also connected to the transformer's leads. Unsolder these as well and push them aside for now.

Next, you'll need an extra heavy duty soldering iron to unsolder the emitter leads from the ground plane on the circuit board. I find it easier to grab hold of the emitter lead with needlenose pliers and gently pull up on the lead while applying heat from the soldering iron. There is not much room to work with desoldering braid. Do the same for the base lead, but be careful you don't pull up the copper pad from the board. You can now lift the device out of the PA compartment.

Installing the new transistor is a bit easier. First, take your soldering iron and smooth out any rough spots on the PC board where the emitter lead will go. Do the same for the base lead as well. You want these two connections to be as flat as possible to ensure good contact with the ground plane. The emitter lead must be soldered as close to the ground plane as possible.

"The mixer worked and had output on all bands."

After you have prepped the areas to be soldered, put a glob of thermal goo to the heat sink and install a new mica insulator. Just in case the hardware is beyond use, Radio Shack™ sells a TO-220 mounting kit, complete with insulators and mica washers for about a buck.

Adjust the leads of the transistor so they match the PC board. Now, tighten down the hardware. Check to see if you have the transistor twisted in such a way as to short the tab (collector) to the ground plane on the PC board. After you have check one more time for alignment, solder the leads down. Installing the transistor this way prevents adding stress to the body should you install the transistor slightly off square. Finish up the job by installing the other transistor.

As a precaution against cooking the power supply, check the collector of each transistor for continuity to ground. Do this *before* you finish reinstalling the various transformers. If you have a collector shorted against the ground foil, it's best to fix it now.

After replacing the finals, I attached the PA to the back of the Century 21. I then attached all the interconnection cables and applied power to the rig.

At key down, the RF drive was slowly increased until the output meter began to show and increase. For a few seconds, I had about 40+ watts of RF output, until the smoke came billowing out of the PA compartment once more. Now, I don't know about you, but I really don't care for 40 meter CW with a smoke detector blaring in the background.

The first thing I thought of was the new finals going up in smoke again. However, after opening the PA compartment once more, I found the final transistors in good shape. The two driver transistors and their emitter resistors were history!

Replacing the drivers' transistors requires the same amount of work as replacing the finals. The drivers are in a smaller case and thus are a bit harder to get in and out of the circuit board. The driver transistors are MRF 472s.

Again, the drivers are not on the shelf at the local Radio Shack™ so another call to Ten-Tec was in order. The 1 ohm half watt resistors were made of carbon and not metal film. I ordered a handful just in case. Nothing was left of the originals except some burned leads and dust.

Since the drivers must be replaced, the driver bias must be

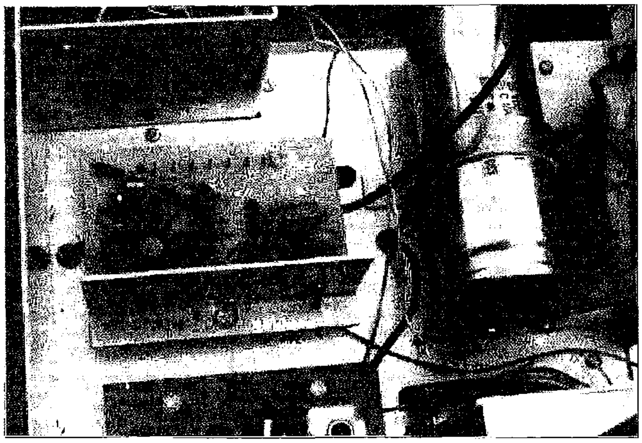

Photo B. The low level RF driver is mounted to a small heat sink. This board plugs into a chassis-mounted socket.

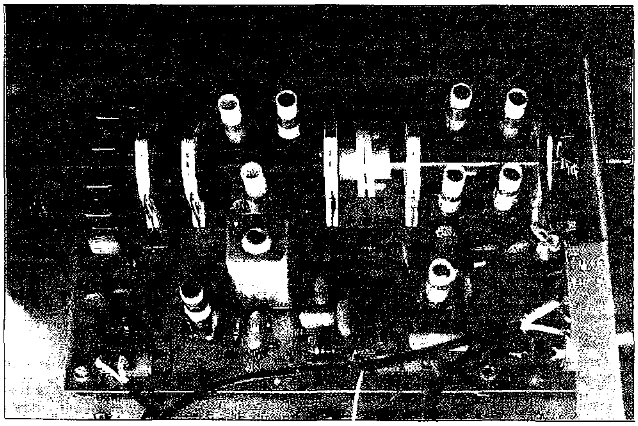

Photo A. The mixer/oscillator board contains most of the band switching components.

set. You accomplish this by inserting an amp meter in series with the +12 volt lead of the PA. You then apply power, and adjust the bias trimmer for about 6 mA.

One more time, the PA was reassembled and tested. On all bands, except 20 meters, I had 40+ watts.

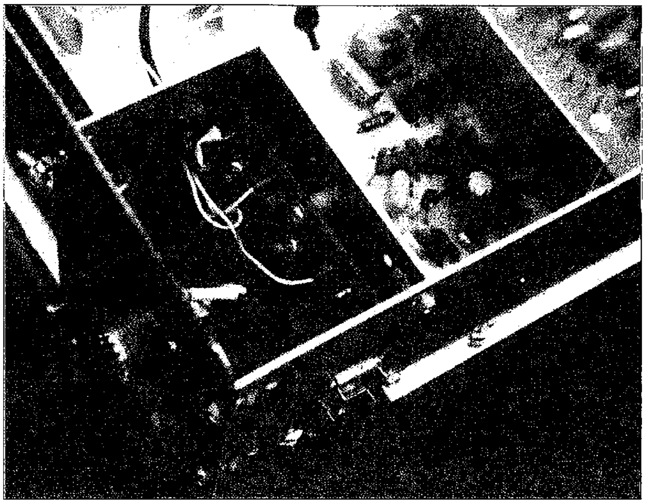

Photo C. Looking down inside the output filters. The driver can be seen sitting just behind the filter.

A Dead 20 Meter Band

The Century 21 mixes the VFO with an external signal provided by a separate heterodyne oscillator to produce the desired transmitter signal. This oscillator and its associated components are located on the 80358 mixer board. (Photo A).

The mixer uses a single MPS3563 transistor. A rotary switch selects the proper crystal according to the band selected. The output of the oscillator is then mixed with the incoming VFO by IC1, a MC1496. The out from the mixer is routed through a series of tuned circuits.

Since the oscillator is common to all bands, and every band worked except for 20 meters, I suspected that the 20 meter crystal was kaput. Checking the output of the oscillator with a scope showed plenty of oomph from all bands. The mixer worked and had output on all bands. That had to mean the signal was stopping someplace in the tuned circuit for 20 meters.

I've mentioned this before many times: Never start messing with alignment settings. But in this case, I did notice the slug of the 20 meter coil was at the very bottom of its core. With a scope, I adjusted it until I could see some output. The coil is fairly broad, so there is no peak to the adjustment. The mixer board also supplies the required signal to the receiver section.

That seemed to fix the problem on 20 meters. I never did connect the antenna to the rig, so I *may* have fixed two problems!

Since I had to tear down the Century 21 for most of these repairs, I decided to replace the spot and drive pushbuttons on the front panel. Ten-Tec no longer stocks replacements for these switches. They suggest a switch available from Radio Shack™, a 275-618 momentary contact type. You must remove the knobs, control nuts and front panel to get to the switch mounting clips. Since the spot switch was broken, I cut the switch clips with a pair of side cutters and saved myself some time.

"I found it a pain in the butt to wrestle with the speaker..."

I found it a pain in the butt to wrestle with the speaker while working on the Century 21. I added a small 156 header and socket so I can disconnect the speaker from the rig. The connector pair is made by AMP, but you need a special tool to crimp the wires. A trip to Radio Shack™ will yield a nice selection of AMP connectors which are easier to install.

There are two other items worth taking a look at. One is the offset balance control located on the control board. You can adjust this trimmer by listening to the pitch of the signal when the ZERO BEAT switch is closed. Adjust the trimmer so the pitch between the two conditions is the same.

The second check is the PTO. There are no adjustments inside the PTO that you should mess with. But do check the condition of the PTO shaft. If it is dry, apply a very light coat of lubricant. Don't get carried away; too much goop and it will end up on the display and inside the PTO.

The Century 21 by Ten-Tec is easy to work on. Its open chassis and plug-in boards are simple to remove and repair. In operation, the design is simple to operate. You can reduce the drive and run the 21 at QRP power levels. Or, if you're one who likes a change of pace, bypass the PA and route the low level driver directly into the filter stages. The driver should be able to do about a watt or so. 73

NEVER SAY DIE

Continued from page 56

selected, in addition to Budlong, to represent the US at the 1959 world ITU conference in Geneva. When I got there I read through a three-foot stack of papers to find the proposals from the attending countries for the redistribution of the 3-30 MHz spectrum. It looked really serious for us. The ITU hams had been right on target. I attended the US delegation meetings, where I heard the delegates representing the other radio services promising to support the retention of the ham bands. But then, when I took them individually out to dinners to talk, I found that every one of them had confidential private instructions that if their service turned out to be in danger of losing any frequencies, the losses would be taken from the nearest ham band so as to prevent their service from any losses. Some support!

The only hope for saving the ham bands lay with getting the discussion for the redistribution of the 3-30 MHz segment to be postponed until the next conference, which was ten years away. The American delegation members got in touch with the other country delegates, trying to get support for this strategy. They got nowhere. After all, virtually all of the other countries had proposed either getting rid of the ham bands, or cutting them way back.

Finally, they put on some really heavy pressure and got The Netherlands to back us up. Thus, when the conference officially opened, The Netherlands representative got up and dutifully made a motion to put off the re-allocation decisions until the next conference. And, to everyone's amazement, the USSR representative got up and seconded the motion. Since he had a whole string of Soviet and communist countries in his pocket, that was the end of it.

Later I talked with one of the USSR delegates to find out what had happened. He explained that it had to do with Kruschev recently visiting the US and talking with Ike. The USSR wanted to show that they were being more friendly to the US, and thus, being the first international conference to come along, we were the winners. A few weeks later Powers' U2 was shot down over Russia and the frost was back on the US-USSR relations. Whew, were we incredibly lucky at that timing! We came *that* close to losing amateur radio in 1959.

I visited Budlong's hotel suit, again in the most expensive hotel in town. Luxurious! I stayed at a modest hotel, but once the main event affecting amateur radio was over I flew back home to work. Bud stayed on for the whole conference, flying many of the League directors over for lavish parties, all at the members' expense.

Lasers and Power Supplies

Last month I brushed lightly over several comparisons between microwave operation and laser operation. These factors included pointing dish alignment and laser beam accuracy. This month I want to expand on some of those ideas.

One concept I would like to make clearer is the comparison of microwave radiation from dish-type antennas to laser energy as emitted from a laser or optics system that collimates the laser beam. If we compare HF operation on 3 to 30 MHz to operation with a dipole antenna, our antenna pattern is bidirectional. If we change the antenna to a yagi-type beam for the same frequencies, it becomes quite large and cumbersome but does increase the forward radiation of power into a more directional pattern, say 15 to 20 degrees or less for a good system.

Now, if we were to increase the frequency to the microwave realm of 10 GHz and use a dish antenna 30 inches in diameter, this would limit our front radiation of energy to about 3 degrees of beamwidth. Now what does that mean if we are positioned remotely at a distance of 10 miles? Well, we can calculate the answer from the known fact that our angle is 3 degrees and our distance is 52,800 feet (10 miles). You have the top of a triangle and know its angle (3 degrees) and the distance (10 miles or 52,800 feet), making the base of this triangle the radiation hot spot at 10 miles of our dish antenna. The hot spot in this case is our triangle base of 2,767 feet—we can refer to this hot spot as the microwave *footprint* —so, the microwave footprint at 10 miles distance when using a 30-inch dish is about a half mile across.

How do you obtain gain at microwave levels, using this same scenario? Well, let's increase the size of the microwave dish from 30 inches to 48 inches in diameter and watch what happens to power antenna gain. When we increase the size of a microwave dish antenna to 48 inches in diameter, its radiation pattern is focused into a beam something less than 1 degree (that's 1/360th of a circle). What is the footprint at the same 10-mile distance of this arrangement? Its hot spot is about 921 feet, or one-third as big as our previous example, and there is a significant increase in power because it's condensed into a smaller area. Hence, the receiving antenna can capture more of the transmitter power, making for an overall power gain on the transmitter to receiver path. In actual practice, a 30-inch dish exhibits about 35 dB gain while a 48-inch dish has 40 dB gain measured at 10 GHz.

A general rule of thumb is: As frequency is increased, antenna gain also increases when the antenna size remains the same for each frequency. If the frequency remains the same, and the *antenna* is increased in size, there will be an increase in antenna gain.

How Does Microwave Compare to Laser Operation?

Let's look into the optical laser world and do the same type of comparison between a sample microwave system and a laser. What we are looking for is a handle on how difficult it is to focus a spot of light on a distant object. A laser would be focused into a beam much the same as microwave energy. As a matter of fact, the relationship is exactly the same—it's just that the laser is vastly higher in frequency than the microwave system. In this example the microwave transmitter operates at 10 GHz and the laser operates at 470,000 GHz or 632.8 nanometers. Its beam of light is dispersed or spread out approximately 1 millirad. Why did they shift gears and call beamwidth 1 millirad instead of measuring it in degrees? At light frequencies "degrees" is a very large number; millirads are parts of a degree, and more useful.

What, you say, is a millirad? Take my word that it's quite a bit smaller than 1 degree of compass bearings. *Everything* is smaller up in the optical and non-optical light world. Very low frequency operation is our power distribution system's 60 Hz. We all know where HF, VHF, UHF and our microwave SHF bands are. But even higher are the infrared, the narrow visible light spectrum we see, and the higher ultraviolet, X-ray, and Gamma ray spectrum.

> ***"The ignitor circuit is quite ingenious in its function: It's another voltage multiplier circuit, connected in series with the main power supply load."***

The laser's 632.8 nanometers (nm) falls in our visible spectrum, and while most lasers have a beam dispersal of about 1 millirad, how do we figure this in degrees?

We'll go through the math nosebleed again. Dividing 180 degrees by π (3.14159) equals 57.29577 degrees, or one radian. How many radians in 360°? We have $2 \times \pi$, or 6.28 radians in one circle. Check me out—divide 360 by radians. You'll get 1,600 mils in 90° or 6,400 mils in 360°; so in 57.29° (1 radian) there will be 1,018.6 mils. For our purposes, 1,000 mils in 1 radian is close enough. Now, if you factor all this out you'll conclude that a typical laser beam of 1 mrad (millirad) is about .05°. A quick calculation by comparison of laser to microwave beamwidth will show you that the laser is *60* times smaller than the beamwidth at 10 GHz using the 30-inch dish. That relates also to being about 60 times harder to focus the beam spot on a target when measured at great distances. See why we had so much trouble trying to place the spot on a target four miles distant? It took a good part of an hour to accomplish the task when the microwave aiming was done in seconds.

Now, let's look into what it takes to make up a laser power supply. See Fig. 4 for distance measurements comparing a VHF yagi to 30- and 48-inch dish antennas, and finally to a HeNe laser whose beamwidth is rated at 1 millirad.

Laser Power Supplies

A laser power supply to power a glass Helium Neon (HeNe) laser tube requires two power supplies to function. One supply is used to ionize the HeNe gas and the other is required to ignite and maintain the laser in its normal operational mode emitting a laser beam.

The ionization of the gas takes a very high-voltage, low-current pulse type of supply, while the ignition of this ionized gas requires a more stout low-voltage medium-current supply. Voltages for ionization are near 8 to 10 kV at extremely low current. The ignition supply must be capable of supplying about 1,000 to 1,500 volts of DC power at about 10 milliamperes. The intriguing thing about these two power supplies is how they are integrated into one package.

There are several variations, depending on input power requirements. For most industrial applications where there is AC power available, that is what is used. I have observed power supplies that have individual transformers with wiring feeding the

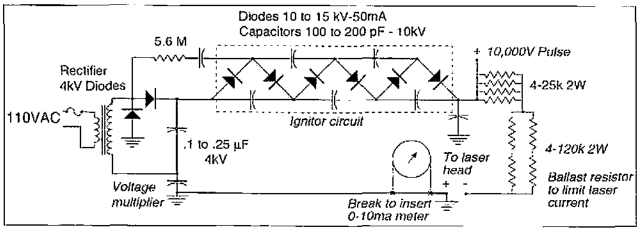

Fig. 1. Basic laser power supply showing rectifier, voltage multiplier, ignitor and ballast resistor circuit.

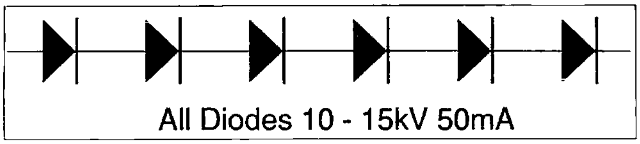

Fig. 2. Series diode rectifier before addition of voltage multiplication circuitry.

high voltage rectifiers and associated circuitry. This type of circuitry usually lends itself to easy component troubleshooting as everything is out in the open.

There are other types of supplies that have integrated all the materials, including the transformer, into a solid block of potting compound, making the unit a single-shot device. "If something breaks replace it" is the right motto for this unit. It does, however, offer reliability and is physically much smaller, making it very attractive (especially in surplus).

Power supply pricing for surplus devices of the open transformer type runs about $20 or less, whereas a similar potted unit can go up to $45 or so. It seems that they are the power supply of choice among power-supply scavengers. Another variation of the potted supply would be one that operates from low-voltage DC input (12 volts), converting the input 12 volts, through a switching supply circuit, to the higher voltage AC, then rectifying it for use. These are most desirable for portable use.

Power Supply Innards

The basic circuitry is varied but the basic type of circuit, in principle, is the same, high voltage of 1,000 volts at several mA of current, with a pulse of 10,000 volts to ionize the HeNe gas inside the laser tube. See Fig. 1 (basic schematic diagram for a laser power supply). As you can see, the circuit is a straightforward rectified AC transformer type of supply, except for the small circuitry attached in the positive lead that's connected to one side of the laser.

This circuitry produces the very high-voltage pulse at microamp low-current levels to ionize the gas inside the laser tube. Here is what is happening: The basic power supply circuit is a standard step-up transformer, feeding a diode rectifier and capacitor voltage multiplier, to produce a steady DC output of 1,000 to 1,500 volts. In series with the power supply is the ignitor circuit which connects to the ballast resistor circuit.

Three main components form a laser power supply: the high-voltage rectifier multiplier; the ignitor; and the ballast resistor circuit. Refer to Fig. 1 for the demarcation points for these three different parts of the circuit. The voltage multiplier portion steps up the input voltage from a low AC value to about 500 volts AC in the transformer. The diode rectifier converts it to DC and the voltage is further multiplied in the capacitor voltage doubler diode rectifier circuit to the 1,000 to 1,500 volt region.

The ignitor circuit is quite ingenious in its function. In fact, it's another voltage multiplier circuit, connected in series with the main power supply load (the laser tube and ballast resistor circuit). The ignitor circuit is constructed with a series string of six special very high-voltage diode rectifiers. See Fig. 2. Alone, these diodes in this configuration only provide a voltage drop across each diode junction, and reduce the power supply output by a few volts.

However, by adding small-value capacitors (100 pF), as shown in Fig. 3, to the series diodes changes the whole picture. We still have the small voltage drop across each diode, but during the period when the laser tube is in a static cold non-light-emitting period, drawing virtually no current, this network multiplies the power supply voltage from 1,000 volts to a pulse of high voltage near 10,000 volts.

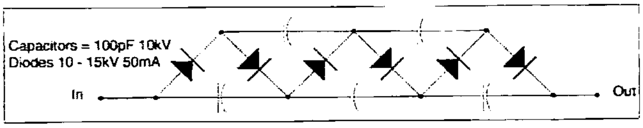

Fig. 3. Complete circuit of voltage multiplier used for laser ignition. Voltage required: approximately 10 kV.

The current that this circuit can furnish is minuscule in the microamp range but is enough to ionize the HeNe gas in the laser tube, allowing it to function with the lower-voltage DC power supply which furnishes current now conducted via the ionized gas in the laser tube. The ignitor circuit cannot supply voltage multiplication with any applicable current flowing, due to the very low value of capacitors and the efficacy of this high-order multiplier. When low voltage (1 kV) current starts to flow through the ignitor series diode circuit towards the laser tube load, the ignitor multiplier action ceases to multiply.

Blame it on the low capacitance of the 100 pF capacitors and the poor ability of the multiplier to supply any amount of current. Electronically speaking, it sort of disconnects and becomes just a series of high-voltage rectifier diodes. (I hope I haven't tripped over myself trying to explain the operation of the ignitor circuit while explaining its function.)

The last portion of the laser power supply is the ballast resistor, one or a series set of several resistors whose primary purpose is to limit current to the load. The load in this case is the laser tube whose gas is already ionized placing the tube in a conductive state. The ballast resistor will limit the current flowing through the laser tube to a safe level, as specified by the tube manufacturer.

How do you test a laser power supply (if you can get to the various parts of the circuit), and what type of meter do you use? Safety is *always* the foremost concern, so you want to use a testing setup that is suitable for operation at the highest voltage rating of the system, and that's 10,000 volts. I do not recommend trying to use voltmeters and DVMs that are in popular use today. I prefer to use an old RCA Voltohmist VTVM with a 50,000-volt high-voltage probe much like what you would use to check a TV CRT anode high-voltage circuit. Sure, it's yesteryear's circuitry, but for voltage in the 15-kV range it can't be destroyed and affords you, and the meter being used, a high degree of protection.

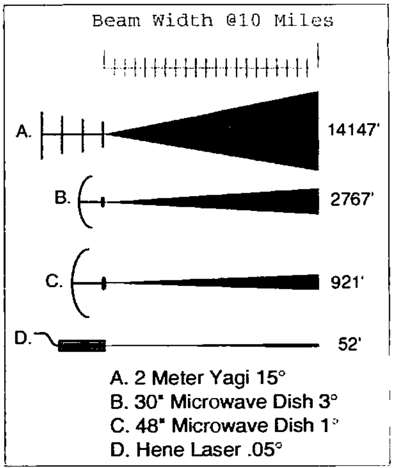

Fig. 4. Beamwidth comparisons between an HF or VHF yagi, a microwave dish antenna, and a HeNe laser. Beamwidth or spot patterns were measured at a target 10 miles distant.

I can't neglect to mention the basic protection and caution when working with lasers: *The voltage being used is deadly.* Precautions should always be taken to ensure proper grounding of all equipment, as well as insulating yourself against accidental contact with any of the high voltage circuitry. This equipment operates with high voltage in the 1- to 2-kV range and should *not* be treated lightly. Yes, it would be safer to employ solid-state laser diodes, as they operate on much lower voltages, but their biggest drawback is that they haven't become available on the surplus market at a reasonable price.

Well, that's it for this month. Next month I'll get into how to start a society or group of amateurs such as our group, the San Diego Microwave Group. I will get into the care and feeding of this group, and the projects that bind us together. 73 Chuck WB6IGP.

Communications Simplified, Part 3

by Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

So far, parts 1 and 2 have dealt with audio and video signals, respectively. Both of these have dealt with analog waveforms. In this part we discuss digital signals.

Digital Data

In its simplest form, digital data is simply a series of numbers. Those numbers could simply be data (such as some company's payroll records), or they could be a digitized analog signal (such as a digitized telephone signal.) As far as sending those numbers from one place to another, it doesn't really matter what these numbers represent, so we won't worry about that at this point.

Although we humans generally use decimal numbers, both computers and communications equipment use binary numbers. The most important reason is that these numbers are less likely to be misread as errors.

Suppose someone asked you to count the beans in a jar, but specified that you are not allowed to use any number that has a 2, 3, 4, 5, 6, 7, 8, or 9 in it; only numbers with a 0 or a 1 are allowed. How would you count?

Like any good computer person, you'd start with zero, and count

0
1

But now you realize you're not allowed to use anything from 2 through 9, and so you skip ahead to

10
11

Now you're stuck again. You can't write down 12, 13, or even 20 or 30 or 90, so you skip ahead to

100
101

Now you again have to skip ahead to

110
111

and now you must skip a whole series of numbers until you get to

1000
1001

and so on.

Congratulations. In writing down the numbers

0
1
10
11
100
101
110
111
1000
1001
1010

you have just invented the *binary number system.* Each of the counts in this table corresponds to one of the numbers of our decimal number system, as shown in Table 3-1.

Table 3-1

Binary	Decimal
0	0
1	1
10	2
11	3
100	4
101	5
110	6
111	7
1000	8
1001	9
1010	10

The decimal number system (from the prefix *deci*, which means 10) has ten different digits, whereas the binary number system (from the prefix *bi*, which means 2) has only two. These two binary digits are called *bits.*

Binary numbers are used because, with just two different digits, it's less likely that they will be confused. For example, in a typical digital circuit, the 0 bit might be something "near" 0 volts, while the 1 bit might be something "near" 3 or 5 volts. As long as the 0 voltage doesn't get too big, or the 1 doesn't get too small, circuitry can still reliably tell the difference between them. If you tried to represent decimal digits with voltages, it might be too difficult to tell the difference between one digit and another if the voltage changed a bit as it travels from one place to another.

DETOUR

There was a very fast swing to the use of digital circuitry back in the 1960s and '70s, when digital integrated circuits (ICs) became cheap enough for common use. The most common digital ICs were called Transistor-Transistor Logic, or TTL.

TTL ICs work on two different voltage levels. Anything between 0 and 0.8 volts is one voltage level, while the other is anything between 2.0 and 5.0 volts. Many users call the near-zero voltage level a 0, and the 3–5-volt level a 1. But this is a bad practice, because many designers use the near-zero voltage to stand for a 1, and the 3–5-volt level be a digital 0 signal, which happens to be the exact opposite. (And many designers even switch back and forth between the two systems, sometimes just a few tenths of an inch apart in a circuit.)

To stay out of trouble, don't use the terms "zero" and "one" to refer to digital signals. Instead, call the 0 to 0.8-volt level a *low*, and call the 3–5-volt level a *high.* This is always safer.

TTL voltage levels are still common today; even though many ICs are no longer TTL, they still usually use the same voltage levels.

Incidentally, the words high and low can be used with other voltages as well. For instance, a high might be +15 volts, while a low might be -10. The only thing required is that the high voltage really be higher than the low.

END OF DETOUR

Although the numbers in Table 3-1 are all different lengths, note that the value of a number doesn't change if you put extra zeroes in front of it. In decimal, for example, 7, 007, and even 00000007 all have the same value. In computers, binary numbers are often stored in groups of eight bits, called a *byte*. Thus the binary equivalent of a 7 would usually appear as 00000111, rather than just 111.

Looking at Table 3-1 again, we note that, if you were limited to one-bit-long numbers, you could only express two different ones: 0 and 1. If you used two-bit-long numbers, then you could express four different numbers: 00, 01, 10, and 11, which correspond to the decimal numbers 0, 1, 2, and 3. Likewise, a three-bit number can have eight different values, which correspond to the decimal numbers 0 through 7. We can generalize this rule as follows: a number with n bits can have 2^n different values, corresponding to the decimal numbers from 0 through $2^n - 1$. For example, an eight-bit byte can have 28 or 256 different values, which correspond to the decimal numbers from 0 through 255.

A typical byte in a computer could represent one of three things:

A number, or part of a number, used in some computation,

An instruction, or part of an instruction, telling a computer what to do, or

A letter, number, or punctuation mark, coded in ASCII (which stands for the American Standard Code for Information Interchange) These are often called *alphanumeric characters*, or just *characters*.

Serial and Parallel Data Transfer

When binary data is moved from place to place, it is most often moved in bytes. A byte can be transferred from place to place in one of two ways:

Parallel transfer: all eight bits of a byte move at the same time along eight separate wires.

Serial transfer: the eight bits travel on one wire, but in sequence ("serially"), one after another.

Actually, parallel data transfer requires more than eight wires. For example, the most common parallel connection is from a PC computer to a printer; this connection usually involves a 25-pin connector and cable:

8 wires carry the eight bits of data

1 wire carries the data-ready strobe, a signal that tells the printer that a byte is ready

1 wire carries a data-received signal from the printer back to the computer

1 wire carries an out-of-paper signal from the printer back to the computer

1 wire carries a busy signal telling the computer that the printer is busy

1 wire carries a ready signal, telling the computer that the printer is on-line and ready to receive data.

12 wires connect the grounds of the computer and printer together.

The data-ready, data-received, out-of-paper, busy, and ready signals are often called *handshaking* signals because they allow the computer and printer to agree on when and how fast to send data. The reason for twelve ground wires is that the printer connection is often done with a ribbon cable; in order to prevent interaction between closely-spaced adjacent wires, the 13 signal wires are separated by 12 ground wires.

A parallel connection can be quite fast since (1) all bits travel simultaneously, and (2) the handshaking signals allow the computer and printer to communicate at their maximum speed, yet still slow down if one falls behind. On the other hand, the parallel connection requires a lot more wires (even if you cut it down to the bare minimum number of wires needed.) Hence parallel connections are only used for short distances.

All long-distance data transfer is therefore done through serial connections. In these, all data bits as well as some simplified handshaking signals travel along one wire (although there is also at least one additional ground or return wire.)

RS-232 and Asynchronous Serial

The most common serial connection is known as RS-232. Although it also often uses either a 25-pin or 9-pin connector, only two wires are absolutely necessary in an RS-232 connection: one for signal, the other for ground.

For example, the ASCII code for the lower case letter *a* in a personal computer is 01100001. If you looked at the letter *a* carried on an RS-232 signal wire, with an oscilloscope, you would see the waveform in Fig. 3-1.

First, you note that although the code is 01100001, the bits shown in the figure are 10000110, which is backward. That is because they really *are* sent backward. The rightmost 1 (at the end of 01100001) is called the *least significant digit* or *lsd*, and is sent first; the leftmost, called the *most significant digit* or *msd*, is sent last. There is a historical reason for this, which we'll see in a moment.

Next, you will note that a 1 is a negative voltage, labeled as -V in Fig. 3-1, while the 0 is a positive voltage labeled +V. The precise voltages are not specified, and could be anything from 3 volts up to 15 volts. Hence, in one system the voltages might be -5 and +5 volts, while in another they might be -12 and +10, or whatever.

There is room for some confusion here, since many people wrongly think that a 1 has to be more positive than a 0, which of course is not the case here. To avoid that problem, many communications people therefore call the 1 signal a *mark*, while the 0 signal is called a *space*. (To use our earlier terminology, a the mark or 1 signal is the low here, while the space or 0 signal is high.)

At the top of Fig. 3-1 is the notation "1 bit time" which shows the length of one bit. Within the byte, each bit has exactly the same length, which we call a *bit time*. The string of four zeroes in the middle, for example, is exactly four bit times long. Both the sender and the receiver must agree on the exact length of a bit so that, when a string of ones or zeroes arrives, the receiver can determine exactly how many bits there are in that string.

Once we know the length of one bit, we can calculate the maximum number of bits per second. For example, if each bit is 1/300 second, there could be a maximum 300 such bits sent per second. Thus the *bit-per-second* or *bps* rate is defined as

bits-per-second = 1/(1 bit time)

Since both the sender and receiver have to agree on the bit-time (and therefore the bps rate), there are certain bps rates which have become

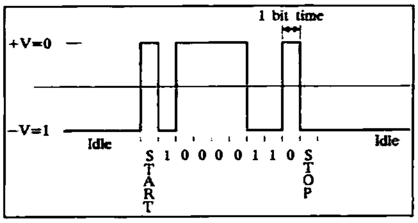

Fig. 3-1. A serial RS-232 letter "a"

standardized over the years. These are 300, 600, 1200, 2400, 4800, 9600, etc. You can see the pattern in these. Incidentally, you often see the bps or bit-per-second rate referred to as the *baud rate*. This is not entirely right, since baud rate has a different meaning from bps; still, it's a common use, and we might as well live with it. (When we get to discuss modems, we will see what the difference is.)

Although the timing of the bits within a character is very exact, the timing between characters is not. For instance, if the signal is coming from a keyboard, there might be long spaces between characters as the typist is searching for the next key. For that reason, this kind of serial data transmission is called *asynchronous*, meaning not synchronized. The bits are carefully timed (synchronized to a clock), but the characters are not.

Thus there has to be a way of telling the receiver when there is nothing being sent, and when the next character begins. The "nothing is being sent" condition is called an *idle*, shown as a 1 or mark signal in Fig. 3-1. Note that there can also be a 1 or mark signal inside a character, but that will generally be shorter.

The "character is starting" code is called a *start pulse*, and is always a 0, or space, which follows the idle. Thus a long mark (1) followed by a space (0) pulse marks the beginning of a character.

Since the sender and receiver will always agree beforehand on the number of bits in the character (usually eight), they can count bits from the start pulse and figure out when the character is over. Hence they don't really need a stop signal. Nevertheless, there is always a *stop pulse* sent at the end, which is always a 1. This is another of those historical things, dating back to when mechanical distributors (much like the distributor in a car) were used to convert to and from serial data in teletype machines. These distributors were run by a motor, and a clutch needed time to start and stop the distributor for every character. In fact, these systems often needed extra time, and so the stop pulse was extra long. We still sometimes hear of "two stop pulses," which really just means a stop pulse of double the normal length.

When serial data is sent slowly, such as from a keyboard, the stop pulse is usually followed by another idle signal of some unknown length. But when the data comes from a computer, it can come at maximum speed. In that case, the stop pulse might be immediately followed by another start pulse, with no idle between them. If you start watching such a data stream in the middle, things can get somewhat confusing since you can't tell which zeroes are start pulses, and which zeroes are data bits. To be really sure, you have to go back to the last previous idle time, and start counting bits from there. Computers also often get confused—if you temporarily break the connection in a serial line you mess up the timing, and all the following data may be wrong until things slow down and the next idle reestablishes synchronization.

In any case, we now see that an eight-bit byte sent on a serial line actually takes a total of ten bits. The addition of the two start and stop bits adds a 25% *overhead* which slows down the transmission. (Hence computer-to-computer data transmission often uses *synchronous* transfer, which doesn't waste as many bits.)

Parity

Let's return to ASCII for a moment. As mentioned earlier, ASCII is a code for encoding letters, numbers, and punctuation marks into binary bits. Although we earlier said that the code for the letter *a* is 01100001, that's not quite true. The true ASCII code is just seven bits, and so it's really just the seven bits 1100001. So where does that eighth bit come from?

Since computer memory locations (at least, those of smaller computers) come in eight-bit bytes, there is an extra bit left over when storing a seven-bit ASCII character in such a memory location. This extra bit can be treated in several ways.

It can be left unused. But since you can't just leave the bit empty, you must put something into it. Hence you could routinely just force it to be a 0 or a 1. In this case, the letter *a* could be stored as 01100001 in some computers, and 11100001 in others.

It can be used to increase the number of available characters. For instance, in PC-clone computers, this extra bit is a 0 for all normal characters, but becomes a 1 for special characters. For example, 01100001 in such a computer is still an *a*, but 11100001 is used to store the Greek letter ß This allows the computer to use an extended character set which includes symbols like ±, π, √, ≥ and °, which are not in the regular ASCII code. This code is sometimes called *extended ASCII*.

It can be used for *parity* error checking. This is not usually done in small computers, where errors tend to be rare, because signals travel shorter distances or because other methods are used to check and correct errors. But parity checking is common when data travels a long distance.

Parity comes in two types—*even parity* and *odd parity*. In even parity, the eighth bit is chosen so that the total number of ones in the character is even; in odd parity it is made odd. For instance, the ASCII code for *a* is 1100001, which has an odd number of ones. For even parity, an extra 1 would be added so that the total number of ones in 11100001 is even; in odd parity the extra bit would be 0 to keep the odd number of ones in 01100001. Another example is the capital letter A, whose ASCII code is 1000001. This would become 01000001 in even parity, and 11000001 in odd parity.

If you've ever seen abbreviations like 8N1 or 7E1, now you can understand what this means:

8N1 means eight data bits with No parity bit, and one stop pulse.

7E1 means seven data bits plus an Even parity bit, and one stop pulse.

Note that the circuitry can't generate or check a parity bit until it has the remaining seven bits of the character. This is the reason why each byte in an RS-232 serial line is sent backward—to put the parity bit at the end, after all the previous data bits.

Error correction and error detection

The idea behind using parity is that every character sent has a specific 0 or 1 bit in that eighth or parity position, determined by the rest of the bits. If any one of the bits in that group somehow gets changed due to an error in transmission, the number of ones will add up to the wrong number, and the receiver can detect that an error has occurred. But note that if two bits (or any even number of bits) get changed, the error can't be detected. For instance, if the 01100001 for an odd-parity *a* gets changed to 01100111, the number of ones is still odd, but the *a* was changed to a *g*

without the receiver being able to detect a parity change. The reason is that with just one parity bit, the chance of an error occurring but the parity still accidentally being right are 50%.

Detecting, and even possibly correcting, errors in digital data is important, because an error in just one bit can make a huge error. Hence the parity bit is a useful step, but not enough.

There are a number of ways of handling errors. The most important step is to be able to detect them, because once you know an error has occurred, you can take steps to fix it. One way is to increase the number of parity bits to reduce the chances of an error going by unnoticed; in this case these bits are usually just called error-detection bits, rather than parity bits.

One common way to do this is to generate a CRC or *Cyclic Redundancy Check* number with a CRC generator. The CRC generator is basically a number of computer building blocks called *flip-flops* (usually 16, although more or fewer can be used), which are interconnected using additional computer components called *gates*.

The flip-flops are computer circuits which can store either a 0 or a 1 bit. Initially, all the flip-flops are set to hold a 0, and then the outgoing string of bits in the sender is passed through the chain of flip-flops. After all the bits pass through, some of the flip-flops wind up holding a 0, while others hold a 1. The precise bit pattern in the flip-flops depends on what data went through and how they are interconnected. If there are 16 flip-flops, then they wind up holding a 16-bit number called the CRC, which is then sent after the data as an extra set of bits.

In the receiver, an identical CRC generator circuit receives the data, and also generates its own CRC. If there was no error, the CRC sent by the sender should therefore be identical to the CRC generated in the receiver. If they are different, then an error occurred somewhere along the way.

When 16 flip-flops are used to generate a 16-bit CRC, the CRC number itself could have any one of 2^{16}, or 65,536 different values. When an error occurs, there is only 1 chance out of 65,536 that the resulting CRC will accidentally be the same as the correct CRC that was generated by the sender. This means that only 1 out of 65,536 errors is likely to sneak through without being caught; in other words, 65,535 times out of 65,536 the error will be detected, which means that the data has a 99.998% chance of being correct. That's a lot better than the 50% chance with just a single parity bit!

Even with just an 8-bit CRC which has 256 possible values, there is a 255 out of 256 probability, or 99.6% of an error being detected.

When an error is detected, how do you correct it? There are two ways: *backward error correction*, and *forward error correction*.

In backward error correction, when the receiver detects an error it asks the sender to transmit the data again. Forward error correction involves sending enough extra (called *redundant*) bits right away so that the receiver can correct an error without asking for a retransmission.

Backward error correction is fairly straightforward. It's what we use every day when we say to someone, "Huh? What was that? Say it again?" The only catch with it is that we need what is called a *reverse signal path*; that is, we need some way of getting a message from the receiver back to the sender. In many communications methods there is a two-way path, so it's easy to get that message back to the sender; sometimes, though, that reverse path may not be present. For example, if a sender (such as a pager transmitter) sends a signal to many different receivers (such as pagers), it's not practical for each receiver to be able to reply to the sender.

Even in simple cases, sending a reverse message asking for a correction takes extra time. Thus backward error correction is more useful if there are relatively few errors so you don't have to ask for too many repeats.

Forward error correction is more interesting, and more difficult. It uses a class of *error correcting codes* or ECC which have built-in redundancy.

Redundancy means including more information than really necessary. For example, the English language has a lot of redundancy, because you can often remove a lot of letters from a message without losing essential information. Consider the sentence "Ths sentins has a lutt of errurs." Even though there are missing letters, extra letters, and even some wrong letters, you know what it says. That's because of redundancy.

The same can be built into computer messages. As a really simple example (since most ECC codes can be quite complex), consider what is called *longitudinal parity*. Let's say you send the word Help in ASCII with even parity:

H = 01001000
e = 01100101
l = 01101100
p = 1111000

so the message reads

01001000
01100101
01101100
11110000

If one single bit somewhere in the four bytes gets changed, you can detect the error and you know which *letter* is wrong, but you cannot correct it because you don't know which *bit* of the eight in that letter is wrong. But suppose you add an additional set of even parity bits, called longitudinal parity, going down the list, like this:

01001000
01100101
01101100
11110000
10110101

The fifth group of bits has been chosen so that *the number of ones reading down any column is also even*. Now suppose an error occurs so *one* of the bits somewhere gets changed, such as the fourth bit in the third row, which got changed from a 0 to a 1:

01001000
01100101
01111100
11110000
10110101

As a result, the third row now has the wrong parity because it has an odd number of ones; the fourth column now also has the wrong parity. We therefore know that the error is in the third row and fourth column, and so we can change the bit in that position from a 1 back to a 0.

This kind of error checking can detect and correct a single bit error, and can detect (but not always fix) a two-bit error. That isn't good enough for most communications applications, because quite often noise bursts and other problems cause an entire series of bits to be wiped out. Hence more sophisticated error correction methods are used, but other than knowing about them, we need not really study them further at this point.

Synchronous Serial Data Transfer

The asynchronous serial method we've discussed so far has the advantage of being simple, but it also has a number of disadvantages. The primary one is that it is inefficient—not only are there two overhead bits for every eight data bits (which wastes time), but the parity bit (if used) adds still another wasted bit that doesn't really do a good enough job of detecting errors. Synchronous data transmission is a way around that. But because it is more complicated, it is generally only used in high-speed applications, such as when two computers are communicating directly with each other. You will seldom see it in a home or small office PC.

In the synchronous method, many bytes of data (usually some power of 2, such as 128 or 256) are sent, one right after another, without separating them by stop and start bits. But now timing becomes very important because a very large number of bits is sent in arow, and even a slight error in timing them could cause a miscount. Error detection is also important, because in a long string of bits there is a greater probability of something going wrong. Synchronous data transmission therefore usually works something like this:

When there is nothing to send, the sender sends an idle signal. What this is depends on whether there is only one sender on the line, or whether the same line might be used by several senders. If there might be multiple senders, then the idle is nothing—not mark or space, but literally nothing—an open connection. If there is only one sender, then the idle is more likely to be a continuous string of bits rather than a continuous mark or 1 signal. For example, the system might send a continuous string of 01010101...bits.

To signal the start of data, the sender sends a different series of easily recognizable bits, instead of a start pulse as in asynchronous data. For example, the sequence 00111100 or 10010110 might be used; both of these are sufficiently different from the idle to be easily recognized as something new.

Next comes the data, generally as a fixed-length group of bytes. Typically there might be 128 or 256 bytes, though it might be some other power of 2.

After the data would come a CRC, usually a 16-bit number, which provides a fairly good probability of detecting errors. The CRC might be followed by another short idle signal, or there might be another start sequence.

Back to bandwidth

In previous parts, we discussed the bandwidth needed for audio and video signals. What about the bandwidth for digital data?

Although digital signals don't exactly consist of square waves, they look close enough to square waves that we suspect that there are a lot of harmonics. Although we haven't specifically said so before, a general rule of thumb is that the faster signals change—the more kinks and corners they have—the higher the frequencies in that signal. This almost certainly means that there will be a lot of harmonics, and so it implies that we need lots of bandwidth.

That is generally true; fortunately it's not as bad as it seems. As we mentioned earlier, the reason that binary numbers are used instead of decimal numbers is that it is easier to tell the difference between a 0 bit and a 1 bit than to have to tell the difference between ten different digits. Even if a digital signal gets all distorted, it may still be possible to read it without errors as long as the ones and zeroes do not get totally confused with each other.

For example, Fig. 3-2 shows a "before" and "after" comparison of a digital signal that went through a communications circuit whose bandwidth was too low, so that many of the harmonics were reduced or eliminated. This much distortion on an audio or video signal might be disastrous; yet the digital signal can be recovered from the "after" signal with fairly simple circuitry. The timing will be slightly changed, but even that can be fixed. As a result, the digital data would go through this system without major errors.

Let's keep in mind that there is no such thing as a perfect communications circuit. There is never enough bandwidth, always a bit too much distortion, always a bit too much noise. These will always affect an audio or video signal in some way; in fact, they will affect all analog signals, and once some noise or distortion affects an analog signal, it is almost impossible to clean it up again.

Digital signals, however, behave differently. As long as the 0 and 1 bits are recognizable, they can usually be recovered and the original digital data will come through without change. And once recovered, that same data can be sent once again through another circuit. Thus, as long as you *regenerate* the data often enough, you can send it as far as you'd like without its being corrupted. This is one big advantage of digital data transmission over analog data.

Claude Shannon, a Bell Laboratories mathematician, calculated back in 1948 the absolute maximum theoretical number of bits that can be sent through a communications circuit in one second as

max bps = $BW \log_2 (S/N + 1)$ where BW is the bandwidth, and S/N is the signal-to-noise ratio—the ratio between the signal power and the noise power.

Mathematicians call the expression $\log_2$ in this equation the "logarithm base 2." Calculating it is somewhat difficult, so for a good approximation let's think of it simply as the number of bits needed to represent the value of (S/N + 1). For example, let's consider a telephone line with a bandwidth of 3000 Hz, and suppose the power of a telephone signal is 30 times higher than the power of the noise, so $S/N = 30$. We need 5 bits to represent the number 31 (which is 30 + 1), so the theoretical maximum number of bits per second in a telephone connection would be 3000 times 5, or 15,000 bps. (With modern telephone lines, and with some tricks to compress data, it is possible to go somewhat higher.)

Depending on the quality of the connection, sometimes the data may have to be sent too slowly to be of use, and sometimes error correction may be needed. But digital data can be sent almost unlimited distances almost without errors—as long as it goes slow enough.

For this reason, sending audio and video analog signals digitally is a useful technique. We will return to this concept later; for now we need just say that the idea is to take the audio or video signal, digitize it with an *analog-to-digital converter*, send the digital information,

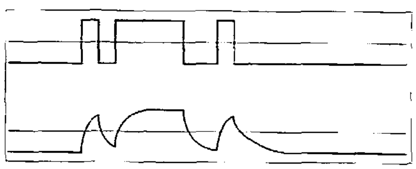

Fig. 3-2. A digital signal, before and after distortion

A Simple Capacity Meter

Have fun building your own with this simple construction project.

J. Frank Brumbaugh KB4ZGC
Box 30
Salinas PR 00751-0030

Grab bags of capacitors, as well as similar assortments of small components including capacitors, are often offered at low prices by mail-order surplus parts dealers. Similar opportunities for stocking up cheaply on small parts present themselves at every hamfest flea market. The methods used for marking capacitance values, usually consisting of a code indicating the value in picofarads or nanofarads, etc. Sometimes they are marked only with a manufacturer's "house" number. The codes are all different and are often confusing. We need something to bring order out of chaos and allow easy determination of capacity values.

"This simple capacity meter uses the fewest, least expensive, component parts, most or all of which can be found in any ham's junk box."

There are, of course, very expensive LCR meters available commercially, at prices well over $100, which measure capacity as well as inductance and resistance. Full-function digital multimeters (DMMs) with prices starting around $75 usually provide a means for measuring capacitance, but instruments such as these are usually beyond the average ham's budget. What is needed is an inexpensive, simple to construct and use, instrument to measure capacity over the most important range used in ham equipment.

The instrument described here uses the fewest, least expensive, component parts, most or all of which can be found in any ham's junk box. It measures capacity over the range of approximately 25 pF to 0.002 µF, the range which encompasses those capacity values which usually must be known. In only a few circuits—AF and RF filters, for example—is it necessary to select specific, usually nonstandard, capacity values. Often a trimmer capacitor is added, such as in VFO circuits, to adjust capacity to a specific value. But all components in a circuit have tolerances of 5, 10, 20 percent or more, and because electronics is a world of varying tolerances it is not necessary to know the value of a capacitor to the last picofarad. You only need to discover where in the table of standard values an unknown capacitor belongs, considering its manufacturing tolerance, which is often unknown.

For example, an 820 pF ±5% capacitor can have a capacitance between 779 pF and 861 pF and still be considered an 820 pF capacitor. If the tolerance is ±10%, which is more common, its actual value could be anywhere between 738 pF and 902 pF. But it is still an 820 pF capacitor and is so marked.

Stray (unwanted) capacitance is added to every circuit whenever a wire or component is added. You can't avoid it; usually it's not important except in a few circuits, particularly at VHF and above.

As an example, this instrument is *theoretically* capable of measuring to as low as 1 pF, but in the real world stray capacity prevents measurement much below 25 pF. It could be easily modified to measure much larger capacitances, but since capacitors of 0.001 µF and larger are usually used in bypassing and decoupling where tolerances of the circuit are so great, whether you use a 0.01 µF or 0.1 µF capacitor, the circuit will function correctly.

The Circuit

Fig. 1 shows the schematic diagram of the Simple Capacity Meter. U1 (a 74LS00 logic chip), two resistors, a capacitor and a crystal form a crystal oscillator operating near the marked frequency of the crystal.

The RF voltage is taken from pin 8 through isolation capacitor C3 and applied to the modified Wheatstone bridge circuit. R3 forms two arms of the bridge, with the arms ratio variable through the position of the wiper of R3. C5, which should be the stable capacitor specified in the Parts List, and the unknown capacitor to be measured form the remaining bridge arms. R3 is adjusted for bridge balance, indicated by a dip–minimum shown on microammeter M1, and the value of the unknown capacitor is indicated on the calibrated dial attached to R3.

The instrument is powered by BT1, a 9-volt battery, controlled by ON-OFF switch S1. This 9 volts is reduced and regulated by U2, a 78L05, to the +5 volts required by U1.

Construction

The circuit should be constructed on a piece of perfboard, or on one of the small general-purpose printed circuit boards available at Radio Shack. It should be mounted in a plastic enclosure rather than an aluminum case, or one made from printed circuit material. This will greatly reduce the unwanted stray capacity.

Leads from the top of R3 through C5 to Jl must be as short and direct as possible. Leads connecting to Jl and J2 should be of solid wire, run as directly as possible. Leads of D1, especially the anode lead, should be very short. Hold the diode leads close to the diode body with needlenose pliers or an alligator clip to serve as a heat sink to protect the diode when soldering its leads. The leads of C6 should also be as short as possible.

Meter Ml can be any of the inexpensive plastic edgewise or square surplus tuning meters originally made for CB or home entertainment equipment. They are available at hamfests and also from several mail-order surplus parts dealers for $2 or $3 each. Movements are d'Arsonval and usually between 200 and 300 microamperes. However, if you own an analog VOM with a current range scale of 100 to 300 microamperes, you could install another pair of binding posts instead of Ml, and use the VOM on the proper scale in its place, saving the cost of a meter.

You will have to make a dial for R3. Most hams save the circular metal cutouts resulting from holes for meters and speakers. These make ideal dials when white card stock is glued to one side, trimmed, and the blank dial centered and cemented or epoxied to the bottom of the knob for R3.

If you do not have such a circular cutout you can scribe a circle on a sheet of heavy, stiff plastic or cardboard, cut it out carefully with scissors or a hobby knife, then cut a hole in the exact center the diameter of the shaft of R3. If your dial does not have a clean white surface, glue a piece of white paper or index card on it. Trim it when the adhesive has dried, and cement or epoxy it to the bottom of the knob for R3.

Mount the completed knob and dial on R3. Scribe or otherwise draw an index line on the enclosure extending a short distance from the edge of the dial.

"This capacity meter measures capacity over the range of approximately 25 pF to 0.002 µF, the range which encompasses those capacity values which usually must be known."

Calibration

You will need to borrow or purchase several fixed capacitors to use in calibrating the dial. The following values, all expressed in picofarads, are suggested: 33, 47, 68, 100, 150, 220, 330, 470, 680, 820, and 1,000. Because polystyrene and mylar capacitors are usually very close to the marked values, this variety will provide the most accuracy. Dip mica capacitors with a 5% tolerance is a second option. If you can't get all the suggested values, get what you can and use them. You can calibrate other values any time a suitable capacitor becomes available.

Switch Sl to ON. Connect a calibration capacitor between Jl and J2. Rotate R3 for a dip in the indication on the meter, either Ml or your VOM if used. Mark a short line on the dial in line with the index mark on the panel. Number it with the value of the calibration capacitor. Continue calibrating the dial as just explained, using the remaining capacitors.

The dial will be nonlinear, being crowded at the high capacity end where accuracy is less important, but expanded at the low capacity end where accuracy may be of greater importance.

Operation

Switch S1 to ON. Adjust R3 so its wiper is away from ground. An indication on the meter shows operation to be normal. Connect an unknown capacitor between Jl and J2. Adjust R3 for a dip on the meter. Read the capacity on the dial opposite the index mark.

Because of normal tolerances,, few capacitors will measure exactly at the calibrated values. If the indication is quite close, that is the nominal value of the unknown capacitor. Extrapolate between calibrated values as necessary to identify the capacitance of capacitors lower or higher in the table of standard values. If you cannot get a dip within the range of R3, first check to see that the capacitor leads are firmly connected to Jl and J2. If you still cannot get a dip, the capacitor is probably larger or smaller than can be measured with this instrument. It also may be defective (usually open or shorted).

Switch Sl to OFF when measurements are completed, to save the battery from an untimely demise.

Comments

In the vast majority of circuits, if, for instance, a 47 pF capacitor is specified but you don't have one, you can probably substitute any value between about 33 pF and 68 pF without any adverse effects. Murphy's Law will always prevent you from finding all the parts values called for on the schematic diagram, regardless of how extensive your stock of parts may be. So don't hesitate to substitute, within reason.

When a mica capacitor is called for you can usually substitute a mylar or polystyrene capacitor, and vice versa. If an NPO or COG capacitor is specified, these two types are interchangeable, but do not substitute a different type. Some ceramic disc capacitors are NPO and will look as if the edge opposite the leads has been slightly dipped in black paint. Other than NPO, ceramic disc capacitors are not temperature-stable and their values shift as temperature varies. If an ordinary ceramic disc capacitor is specified, you can substitute any other kind of capacitor for the disc without any problem.

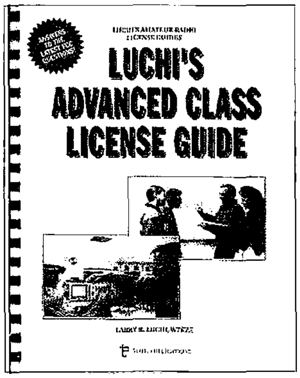
Advanced Class Study Guide



This 185p Luchi (W7KZE) 1995 guide covers the latest FCC question pool, with the questions you'll be facing, the answers, and the explanations. Call it a speed course in radio technology. No fair just memorizing this stuff since you're going to need a real understanding of it to go on to your Extra ticket. And it isn't all that difficult. After all, we have some seven-year old girls with Extras. You're not going to let a 7-yr old kid fake you out, are you? Spend the $23 (+ s/h). Tiare Publications, Box 493, Lake Geneva WI 53147. Get your Advanced ticket and come up and play with the big boys.

New Version of Computer-to-Scanner Interface Software

DataFile Inc. has released a new version of its computer-to-scanner interface software, Probe Version 2.0. The program will allow scanning enthusiasts to lock into active sets of frequencies, and return to normal scanning when traffic diminishes.

Probe was developed exclusively for Optoelectronic's OptoScan 456 and 535 Computer-to-Scanner interfaces, which work with Radio Shack's Pro-2005, 2006, 2035, and 2042 scanners. Over 70 new features and enhancements have been added to Probe.

SmartScan™ allows the operator to select a set of key frequencies. When a key frequency becomes active, SmartScan calls up a database of frequencies related to it and begins scanning them. When activity settles down, SmartScan returns to normal scanning.

Using SmartScan, the operator could select an air emergency frequency as a key frequency. When that frequency becomes active, Probe would begin scanning the local air tower, ground control, fire squad and airport security channels, for example.

The program will run on virtually any DOS-based computer, and is capable of scanning up to 50 channels per second on AT/12MHZ machines without additional memory, graphics cards, or operating systems.

The frequency database engine uses the dBASE format, allowing management of up to 4,000 groups of 99 banks. Each bank may contain up to 1,000 frequencies.

Rubber Duckie Antennas

MFJ has released three new flexible antennas for multi-band and 2M HT users. The MFJ-1717 is 15.75 inches in length, covering 440 MHz (where it is a half-wavelength) and 2M, where it operates as a quarter-wave.

The MFJ1716 is a quarter-wave on 440MHz, and a loaded quarterwave on 2M. It measures 8.75 inches. The MFJ-1718 is a helically wound high-Q antenna for 2M only. All antennas feature a high strength, high flex design with a new rubber coating. Contact MFJ Enterprises, P.O. Box 494, Mississippi State, MS 39762. Tel 800-647-1800.

VISAR Replacement Battery and Eliminator

Battery on that HT going dead in the middle of your first QSO after a night on the charger? W & W Associates has announced the addition of the VISAR replacement battery and eliminator to their extensive line of Two-Way batteries. The batteries are available in 7.5v @ 2000mAh and 7.5v @ 1200mAh.

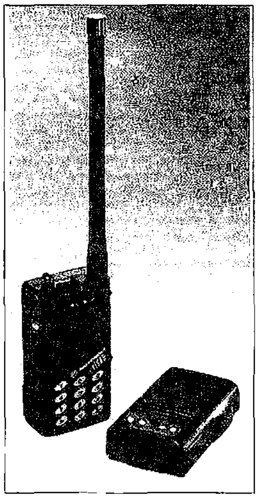
W & W also now stocks batteries for the Yaesu FT-10R/40R, The Icom series IC-W31, IC-21A, IC-T22A, IC-T42A and Alinco DJ190/DJ-G5

W & W can be reached at 516-942-0011 and is located at 800 South Broadway Hicksville, NY 11801-5017.

New HS-1000 All-Band HF Mobile Antenna.

Mobile HF operators have a new choice of antennas. High Sierra Antennas has introduced its new HS-1000 all-band HF mobile antenna.

The design incorporates features such as new low-cost mounting options, center-loading coil for high-power and high-temperature applications, a decoupler system, and improved matching system and a remote control panel with limit indicator.



The antenna provides coverage from 3.5 MHz to 30 MHz and beyond without sacrificing performance on any frequency. The variable loading coil is remotely controlled, so the operator can tune the entire HF spectrum without leaving the driver's seat.

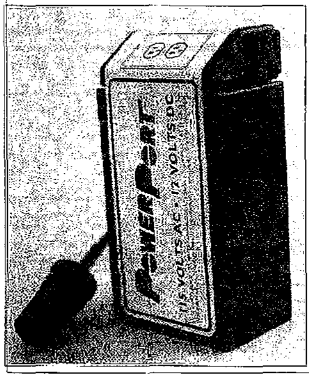
The HS-1000 uses two basic mounting systems. The Easy-off mount allows the entire antenna to be removed in about 30 seconds for safety or security. This method uses a tapered stud at the based of the antenna together with an upper clamping mechanism.

The new single point mounting method allows the antenna to be attached to horizontal surfaces.

The antenna can be purchased as a complete package, or in its component pieces for those who already own some of the hardware.

Portable AC and DC Rechargeable Power Source

Cutting Edge Enterprises has released, a portable AC and DC rechargeable power source.



Unlike currently available 12V power supplies, Cutting Edge's Powerport has an on-board inverter to make both 115V AC and 12V DC power equally available. This compact unit is built around a sturdy 12V 7 amp hour gel cell battery. It can b recharged with the supplied wall charger or, unlike all other models, can be charged in your vehicle without requiring the engine to be running. Price: $89.50 + $6.50 shipping. For more information contact: Roger Hall, Cutting Edge Enterprise, 1695 River Street, Santa Cruz CA 95060. Phone (800) 206-0115; FAX (408) 426-0115.

NEVER SAY DIE

Continued from page 63

So what happened at the next conference ten years later, when the chickens came home to roost? That's another fascinating story. Remind me to write about that. I kept in close touch with the ITU hams for many years, so I knew what was going on from the inside. Also, remind me to write about how I engineered Budlong's forced retirement.

Sue Your Parents

If I weren't an orphan, I'd sure haul my parents into court and sue them for child neglect. This has to do with my reading an excellent instruction book on prenatal care. You're probably too busy in the hamshack to do what it takes to have any kids, but if you do ever decide to take a few minutes off from DXing to have a junior op, get this book and read it or I'll put you high on my list of hams to haunt with high line noise and defective transistors after I win my Silent Key award from the League (which I'm sure they have ready, just awaiting the date).

The book is *Prenatal Classroom, a parents guide for teaching your baby in the womb*. It's by Van de Carr and Lehrer, ISBN 0-89334-152-5, 161p, $13, published by Humanics Learning, Box 7400, Atlanta GA 30309. It doesn't say much that I didn't know before, but it is an excellent instruction book on how to communicate with your unborn child. How to teach it around 50 words, to like music, and stimulate brain growth before birth.

Back in 1950, when I got interested in Dianetics and studied at the Hubbard Dianetic Research Foundation, I found out how much that happens during the prenatal months affects us later on. It is really simple, under hypnosis, to regress anyone to the prenatal period and find the causes of many current-life psychological problems. It's also easy to erase these devilish influences, once you learn the tricks. As far as I know, this stuff hasn't been taught since the late Ron Hubbard, who I knew quite well, started Scientology and using the technology more for brainwashing than helping people. Well, he made hundreds of millions.

Instead of loading up your child with bad baggage, you can give it one heck of a head start by following the instructions in this book. The AMA says this results in significantly higher IQs, which means that if you don't use these techniques, you are permanently robbing your child of mental ability that is inherent. It's bad enough with our schools dedicated to dumbing our kids down without parents adding to the mess.

You can teach your unborn child to communicate with you, to recognize words, and even to like certain foods. One mother, who ate a lot of doughnuts during her pregnancy, had a child whose favorite food was doughnuts. Still is. They call her blimpy. One thing I know for sure, my mother didn't eat much eggplant.

And yes, if you let the poor kid hear a lot of CW, it'll probably grow up to be an ARRL director. I think that's probably what happened to poor old Harry Daniels W2HD, the ex-president of the League and internationally noted Wayne Green fan.

If you're into the grandfather class, be sure your kids get copies of this book to help guide them with your grandchildren.

The one aspect of the book that disappointed me was the lack of any attention to the pre-conception things you can do to give your kids the best chance at not screwing up their lives the way you have. My folks smoked and drank, and look at me, and sigh for what I might have been without the pre-conception destruction of many good traits and zillions of potential brain cells.

It shouldn't be any surprise that what happens during the nine months of pregnancy, when the child is growing from a pin-point fertilized ova into a baby, is going to be a big part of the programming of this new computer. Sure, the genes are like the ROM programming, giving us instincts, but from then on it's RAM memory and little Ickie can hear and record everything going on after just a few weeks. And, after twelve weeks, start tasting. Ickie feels pain, is sensitive to drugs in the mother's blood, and can be seriously traumatized by ultra-sound or the missionary position.

Since Dianetics is a lost art, as far as I know, your best bet is to create as little bad programming as you can and not count on being able to erase it later. I hope that makes sense. Anyway, I think you'll enjoy the book.

Tapping ET's Phone

Cosmologists are having bitter arguments over the age of the universe, complete with wild credential waving to back up unfounded theories. But, whether it's five, ten, or fifteen billion years, or even ageless, the odds seems heavy that (a) there is other intelligent life, and (b) that it is probably millions to billions of years ahead of us in technology.

Radio has been around for about a hundred years. Two hundred years ago anyone predicting that people anywhere in the world would be able to see and talk with anyone else at will would have been locked up in an insane asylum. Well, that was before mental hospitals. Considering that technology developments have been speeding up, I suspect that any predictions we might make for 2096 would be as far off the mark as the 1896 predictions for 1996, where they thought we would be up to our armpits in horse manure in our cities. Instead, it's exhaust fumes.

As soon as a communications medium which is instantaneous and unlimited in bandwidth is discovered, radio will be quickly phased out, just as were smoke signals, then signal lights, and spark transmissions.

Meanwhile, science has, for the most part, turned a blind eye and deaf ear to the tens of thousands of reports from seemingly sincere and sane people who claim to have had contact with visiting ETs, and millions of people who have seen UFOs. Look, once we get far enough developed so we're able to visit planets in other solar systems, I doubt we're going to go in like Captain Kirk and offer to share our advanced technology with some species which hasn't even learned to fly. And how long have we been flying? Well, sure, the Wright Brothers got off the ground in 1908, but I was on the very first commercial flight between Philadelphia and New York, so practical aviation isn't very old.

My dad designed and built the Philadelphia Central Airport (in Camden), so I was right in the middle of the early days of commercial flight. All of the well-known aviators of that era used to come over to our house to visit.

It seems likely that any civilization advanced enough to travel to other solar systems will also have survived their natural warrior background and developed a more peaceful system for living with their advanced technology, so they'll probably visit more out of curiosity than a need to conquer more worlds. And this would mean a low profile, which seems to fit exactly what we're experiencing.

Quantum mechanics is giving us some hints on the possibility for instantaneous communications, and perhaps even space travel over any distance. But QM seems to be a link between matter and thought, so scientists are very uncomfortable with it. We're not sure what matter is yet, and we haven't much in the way of clues about thought. We're like people 200 years ago in this respect, and still ready to crucify any scientist daring to look deeply into these matters. Like the Harvard professor and his recent book on his interviews with contactees.

How about you? Are you a UFO believer? Or skeptic? Do you really believe that every single one of the expert observers who have reported in detail on UFOs has been mistaken or is lying? That every single report, with many based on observations by hundreds to thousands of people, are baloney? How about contactee stories? They are now into the thousands, with most of the people involved keeping quiet about it and wishing it had never happened. Are every one of these people deluded or liars?

Sure, as with any such field, there are a bunch of weirdoes and

Barter 'n' Buy

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The 73 Flea Market, Barter 'n' Buy, costs you peanuts (almost)--comes to 35 cents a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad. This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to: *73 Magazine*, Barter 'n' Buy, 70 Rt. 202N, Peterborough NH 03458 and get set for the phone calls. The deadline for the May 1996 classified ad section is March 12, 1996.

NEVER SAY DIE

Continued from page 75

nut cases. But then we have those in just about every field. You should see the stuff I get in the weird science and health fields! But the trouble is that in amongst the crazies and scam artists there are some serious and dedicated people who should be heard. Sorting the wheat from the chaff isn't easy.

I have a file drawer full of alternative health claims. The part that worries me is that I doubt that 100% of them are phony. So how are we going to find out what's worth while and what isn't? In the health field we know that the medical establishment, which includes our government, isn't going to even try. And we've seen what happens when the government gets involved with UFOs: cover-ups and obfuscation. They throw dedicated scientists into prison and destroy their laboratories, as they have with Wilhelm Reich, Royal Rife, and many others. And tried to do recently with Naessens.

If you are interested in getting involved with the SETI project and lending your radio ear to the multitudes scanning the heavens for errant ET signals, call 800-AU-SETI for instructions. This is a private group, so at least you won't be messing with the government, which I don't trust any further than my vote goes. Which isn't very far. I'm trying to remember if I've ever had a pleasant meeting with government people. Yep, I've had many very positive contacts with the FCC and, since Prose Walker got canned, few negatives. I can't say the same for the IRS, FDA, FBI and a few of the other government strong-arm outfits. But, even if the project fails to detect any ET signals, you'll have had an adventure trying if you get involved. And you'll learn a lot about weak signal reception and antennas.

Frankly, I doubt that SETI is going to accomplish much. We'd do a lot better to look for clues as to a new communications medium. It's really arrogant of our scientists to believe that they've now invented all there is to invent in communications systems. It reminds me of the attempts a little over a hundred years ago to build better telescopes so they could look for smoke signals or mirror reflections from other planets.

Psychic Pets

Have you got a dog? A cat? Some other kind of pet? There's a couple of books I somehow have to get you to read. Yes, I know, you only read technical magazines. Or novels. So how am I going to break you loose and get you to read some non-fiction? Sure, I've read some wonderful novels. I've got 22 shelves of 'em in my library. But few of them added much to my life in the way of understanding. Well, maybe Sinclair Lewis and John P. Marquand's novels were worth while long term.

Back in February I tried to get you to read *Kinship of All Life* by J. Allen Boone. But my recommendation just went in one eyeball and out the other. I know that for a fact because if you had read the book you'd have written, thanking me for allerting you to such an incredible treasure. It's not only an interesting story, it's true, and even worse, it is an instruction manual on how you can communicate with your pet. If you have a problem finding the book you can try Item #5280, Laura Lee Books, Box 3010, Bellevue WA 98009 - 800-243-1053. A reader let me know about that. Get their catalog...it lists several of my recommended books.

You see, animals, lacking speech, communicate on a more psychic level. And they communicate very well without being able to talk. I've had a lot of pets down through the years, so I sure wish I'd known more about how to communicate with them. Let's see, we had a blue and yellow macaw for about 30 years. And there was a rhesus monkey. A six-foot indigo who was very friendly. Greyhounds, Italian Greyhounds, Afghans, Burmese cats, a couple goats, a couple horses, a turkey, an African swan goose, and so on.

While I was down at the Virginia Beach hamfest to give a couple talks, I made my usual pilgrimage to the Edgar Cayce book shop. This time I only found one new book that looked interesting. It was *Psychic Pets* by Wylder, on sale for $6. It was a 1995 reprint of a 1978 book, ISBN 0-517-69265-1; 150p; hardbound. It's packed with stories of psychic performances by pets. Like the pet canary that tapped on the window of the next door neighbor one cold, rainy night. The neighbor opened the window to let it in, but it died at that moment. The neighbor recognized the canary and went next door to tell the owner and found she had fallen and was helpless.

Then there was Sugar, a Persian cat, who was terrified of being in automobiles. When his owner had to move from California to Oklahoma, he gave Sugar to neighbors who wanted him rather than try to force him to make the 1,500-mile car trip. Fourteen months later Sugar showed up at the Oklahoma farm and moved right in. He had an odd hip deformity, so they knew it had to be Sugar, and not a cat that looked like him. They called the family they'd left him with and they said yes. Sugar had left 13 months ago. He walked 1,500 miles and found his family in a place he'd never been before. Sugar had to average about four miles a day, plus somehow get food and water, for over a year!

The book is filled with stories of animals being clairvoyant and warning their owners in time to save their lives, of animals helping each other, and so on. If I run into you on 20m I'll tell you a few more of the amazing stories. Like how cats in London knew a half hour or more before radar was able to pick up incoming raids and headed for the bomb shelters, thus warning the people.

I'll bet you've got an animal ESP story I'd enjoy. The next time I'm in your area, if you have an open repeater that doesn't time out in one minute, I'd love to hear it.

League Bummer

Here goes Uncle Wayne, attacking the poor old League again. So who else has the stupidity to attack a religion in print? This time I thought you ought to know about a letter to *QST* that they're surely not going to publish. It's from Steven Morris K7LXC, griping about the April article, "Dialing For Deals." The article encouraged their readers to whipsaw ham dealers to get the lowest possible price...thereby eventually putting all but the few dealers with the lowest overhead out of business.

As Steve points out, the end result of us always shopping for the lowest possible price forces dealers to give less and less service to compete. Thus the article does a serious disservice to both ham dealers and amateurs. Of course, if you aren't ever going to want any service and are happy to buy everything by mail order from the manufacturer, then perhaps forcing most of the ham dealers out of business isn't a problem. Eventually all manufacturers will have to sell directly via mail order. And that would mean even more ads for *QST*, which could be exactly what the League has in mind in pursuing this tack.

Meanwhile, I'm sure that the few ham dealers left will continue to advertise in *QST*, thus showing their continuing support for the League, just as the whole ham industry did 30 years ago when the League put 85% of the retailers and manufacturers out of business within a couple of years. There isn't the slightest hint that anyone in the ham industry has leared anything from history.

Your First QSO!

I'll bet you can remember your first contact, just as I remember mine. Oh, I'm not counting the times I used fictitious calls and made contacts on 40m CW (called bootlegging in those days). No, my first legitimate contact, license in hand, was on 2-1/2 meters.

The rig was a 1G4GT oscillator-super-regenerative detector, with a 1Q5GT modulator-amplifier. The whole works was built into a one cubic foot walkie-talkie, complete with batteries and a handle. It was a

More Monitors

Last time, we were investigating the repair of hamfest-procured computer monitors. We got as far as replacing the horizontal output transistor. Let's take up where we left off:

Why?

Before we move on from the horizontal section, it would be a good idea to ask just why those output transistors blow out. As I mentioned, they work very hard, and at fairly high voltages and currents. Those factors alone are enough to ensure higher-than-average failure rates. In many cases, the transistor can be blown without the monitor's having any other problems. Sometimes, though, it isn't that simple.

A while back, I ran across a monitor with an odd problem. It was stone cold dead and, sure enough, the horizontal output transistor was popped. A new one brought the set back to life, with a pretty decent picture. Case closed, right? Well, not quite. The seller had been honest and told me that he'd replaced that same transistor just a few weeks earlier. The set had worked for those few weeks and then died again. What was taking out the transistors?

One touch with my finger told me the answer. The heat sink was *hot!* Of course, dissipating heat is the purpose of a heat sink, but this was ridiculous. Within one minute of turning the set on, you could have fried eggs on that aluminum sheet. Heck, my stove doesn't work that fast! (By the way, if you're going to try this test, be darned sure that heat sink is at ground potential first—some of them have serious voltage on them and will give you a lot more than a burn.) What could be causing the heat sink to get so hot, especially considering that the darned monitor worked?

Clues

I was puzzling over this when I took a good look at the screen. The picture looked pretty nice, but the image was a little squashed at the edge; the horizontal linearity was poor towards the right side of the scan. Did that mean anything? I visualized the horizontal current waveform driving that scan. Knowing that TV images are scanned from left to right (as viewed from the face of the tube in the normal position), I realized that the right side of the screen is reached when the current through the yoke (magnetic deflection coils) is at maximum (when the transistor is working the hardest, and its input is at maximum). That non-linearity meant distortion of the scanning waveform. But what would make it distort? Transistors become non-linear when they reach their minimum and maximum limits of amplification. Rather than simply cutting off completely or swinging to the full supply voltage, they begin to amplify less. This occurs only over a very narrow region. Since I knew the transistor was distorting at its maximum point, that suggested that it was being overdriven, out of its linear region. However, if the drive signal were simply too big, the image should have been too wide, perhaps even off the screen. If anything, this one was a little narrower than it should have been. Only one thing was left: the bias had to be too high. In other words, the DC level on the transistor's base had to be too high, causing the transistor to conduct too much, and driving it out of its linear region. That sure would explain the heat!

A quick glance at the circuit board, however, showed that there were no bias resistors going up toward the power supply. The only resistor was from the base to ground. Could it be bad? It checked out right on the money. What else could supply DC to the base of the transistor? Hmmm, there was an electrolytic capacitor coupling the signal to the base. If it were leaking, it might leak some DC from the previous stage, raising the bias. I put in a new cap and, *voila*, all the symptoms went away! The heat sink stayed at finger-touch levels, and the distortion in the scan disappeared. The monitor has worked fine for over a year now. Case closed.

The moral? Sometimes those transistors really do have a reason for blowing out! Usually, though, they just go.

Consequences

Last month, I mentioned that the horizontal outputs generally fail open, not shorted. In hindsight, I think that's not strictly true. What probably happens is that they do indeed short, and all that current going through them then blows them open. But, for perhaps a second or two, they're pretty much a dead short to ground. So what?

That scenario explains the power supply failures often associated with blown horizontal outputs, that's what! Very often, you'll find a blown fuse, which is what leads me to suspect the temporary short; an open circuit won't blow a fuse! Sometimes, there's more damage. Frequently, the power supply is damaged, and replacing the fuse results in another blown one within milliseconds. *Now* what?

Usually, the problem is another blown transistor! Most monitors use switching power supplies. Those things operate at high frequencies, and they work quite hard. In fact, they're a lot like horizontal circuits. Just about every personal computer out there uses one, and millions of them are humming along, year after year, with no problems. So, why do they die in monitors? Many computer supplies have built-in short-circuit protection, and will simply stop and start until the short is removed, with no damage. If you've ever heard a computer supply go "squeak squeak" or "tick tick," you know what I'm talking about.

Monitor supplies, though, rarely have such protection. When a short is placed at the output, the fuse blows. Shouldn't that protect the supply? Yes, but anyone who's spent much time working on solid state gear knows that transistors often wind up protecting fuses! In a monitor, the usual victim is the supply's switching transistor. Like a horizontal output, it's attached to a heat sink. It may be bipolar or FET, but you must replace it with a compatible part; most general-purpose transistors can't take the voltages encountered in these circuits.

Be sure to replace the switching transistor *after* replacing the horizontal output; if you do it the other way, you may just blow the switching transistor all over again, faster than you can shut off the power. Yet another word of caution: Switching power supplies are especially dangerous to service. That transistor is not isolated from the AC line, and touching it is no different from sticking your finger in a lamp socket! Be sure to unplug all power and discharge the supply's electrolytic capacitors before attempting to change the transistor.

Your monitor should be working now! If not, it could have other, more serious problems. If the fuse still blows, there's another short somewhere. Unfortunately, a likely candidate is the high-voltage transformer, or "flyback." Especially on old sets that have been on for thousands of hours, this part can break down. The flyback is what generates that 30,000 volts, so you can imagine the stress on the insulation separating its thousands of windings of very fine wire. Also, there's an integral high-voltage rectifier, and that can short out, too. Testing for a bad flyback isn't easy, because the windings may break down only when high voltage is applied to them, but if the flyback shows burn marks, there's a good chance it's the culprit. I have seen some pretty ugly ones that still worked, though. If the horizontal output blows again as soon as you apply power, suspect that flyback. The unfortunate part is that flybacks are expensive and, unless the monitor is particularly valuable, you won't want to invest the money to try a new one in a set which could still have other problems. Usually, a bad flyback means a ruined set.

PO Box 2508
Fullerton CA 92633

Doppler Antenna Update

"What's the best equipment for winning 2 meter T-hunts?" That's the question I am asked most frequently by hams contemplating their first search for a hidden transmitter. As you might expect, there is no simple answer. I have seen the VHF radio direction finding (RDF) setups of hundreds of hams and they're all somewhat different, just like snowflakes.

To narrow the field, let's presume you're preparing for a beginners' mobile T-hunt. You will probably have to drive at least 10 miles, so you need an RDF setup that mounts on your car so you can find the signal direction while moving along. You don't want to be constantly stopping and getting out to take bearings. This eliminates the "body shielding" technique and simple "bat-wing" buzz-box attachments for your handie-talkie.

The favorite mobile RDF antennas in my area for the bands from 144 to 450 MHz are homebrew quads of three to six elements. Yagis of the same boom lengths are also common. No RDF device in the ham market has more sensitivity than a simple yagi or quad and nothing works better when the hidden signal is horizontally polarized. That's why Southern California hams prefer this method; weak signals are common on our hunts. Of course, a rotating four-element quad is a bit cumbersome to mount on a car, but that's what almost every hunter does.

On the other hand, the T-hunting conditions in your area might be more like those in Phoenix, where hiders usually put out strong signals with vertical polarization. You can use a beam there, as many do, or you can use another popular RDF method that's based on the Doppler effect.

Typical Doppler RDF sets for VHF have from three to eight equally-spaced quarter-wave vertical whips arranged around an imaginary center point on a ground plane. An RF switching circuit connects whips to the narrow-band FM receiver, one at a time in sequence. This makes the receiver think it is connected to a single whip that moves in a circular path around this imaginary center point.

When this pseudo-rotation is done at high speed (approximately 500 times per second), the Doppler effect causes frequency modulation to appear, superimposed on the received signal's audio. It sounds like a tone at the array's spin frequency. The phase of this tone, relative to the whip switching sequence, is processed to determine the direction of the incoming signal. Doppler bearings are usually displayed on a ring of eight to 32 light-emitting diodes. The number of LEDs is independent of the number of whips.

Doppler sets are appealing because they provide instant bearing readout. They are great for tracking short transmissions because they update the bearing many times per second. Since they have no moving parts, Dopplers are easy to install and use on almost any vehicle. RDFers involved in volunteer enforcement like them because they are much less conspicuous than beams. One of the most popular designs for hams is the inexpensive Roanoke Doppler (see sidebar).

Is the Doppler Working?

A lot of my e-mail in recent months has been about my new wideband antenna switching circuit for the Roanoke Doppler. It uses PIN diodes at each end of the four whip coaxes to improve isolation and control impedance at the whip bases. Plans for it are in "Homing In" for April and June 1995. If you missed it, I'm sure the folks in Peterborough have back issues to sell. For the most part, everyone who has written is enthusiastic about its performance.

Jim Baremore K5QQ sent some pictures of his version made from Hustler UGM magnetic-mounts (Photo A). They cost about the same as the CB mounts that I used and he says there is plenty of room to add the resistor and PIN diode in the base. You'll find these mounts at many ham radio stores.

Some correspondents noted that mobile Doppler indications on 440 MHz signals fluctuate much more than on 2 meters. This is normal. RDFers who hunt both bands have seen this phenomenon with both beams and Dopplers. It occurs because multipath becomes more prominent as you go higher in frequency.

Multipath causes several apparent simultaneous bearing directions due to signal reflections from buildings and other nearby terrain features. Since the ability of a surface to reflect a radio signal is proportional to its size and smoothness in terms of wavelengths, there are far more objects around that will reflect 70 centimeter wavelength signals, compared to signals of 2 meter wavelength. The best way to combat multipath is to keep moving and "eyeball average" your direction indications as you go along.

It's always best to verify proper operation of any RDF setup before going out to hunt a signal in an unknown location. The obvious way to check your Doppler would be to take a quick walk around the car with a transmitting hand-held, watching the LED display to see if it follows along. But this is not a reliable method, particularly on UHF. A perfectly good antenna system is likely to give bad results, for two reasons. First, the display electronics and switcher diode currents may be upset by the intense RF field from the HT.

More important, a Doppler array is designed to work with a "planar" wavefront in the "far field," to use some terms that $100-an-hour antenna engineers like to toss around. Put more simply, the wavefront coming off your HT's "duckie" is a circle that expands outward. It's just like the ring of ripples you get when you toss a rock into a still pond. When the transmitter is very close to the receiver (in the "near field"), the part of the wavefront that strikes the receiving antenna has a lot of curvature to it. When the T is many wavelengths away ("far field"), the wavefront circle has become so big that the segment reaching the receiver has very little curvature and appears to be planar.

Another factor to consider is that Doppler accuracy can be degraded by proximity to anything that disrupts the planar characteristic of the incoming wavefront. Other communications antennas on your car may "pull" the Doppler indication in their direction. The effect is most detrimental when whips are in front of the Doppler array or when you have a rotatable beam mounted on the car.

When correspondents tell me that their Dopplers just don't seem to work right, I urge them

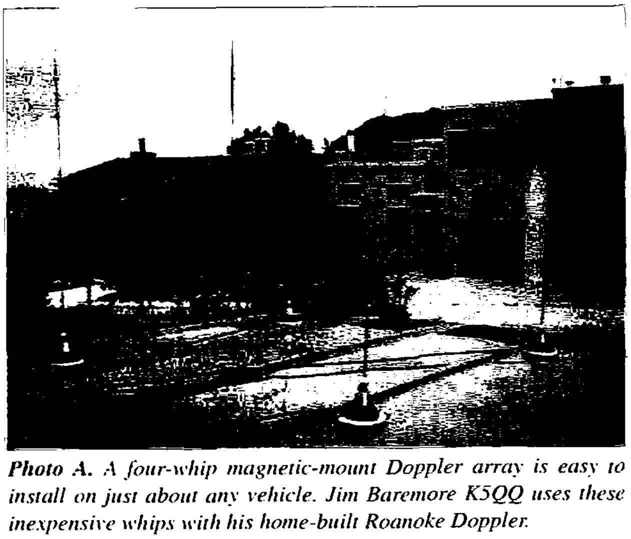

Photo A. A four-whip magnetic-mount Doppler array is easy to install on just about any vehicle. Jim Baremore K5QQ uses these inexpensive whips with his home-built Roanoke Doppler.

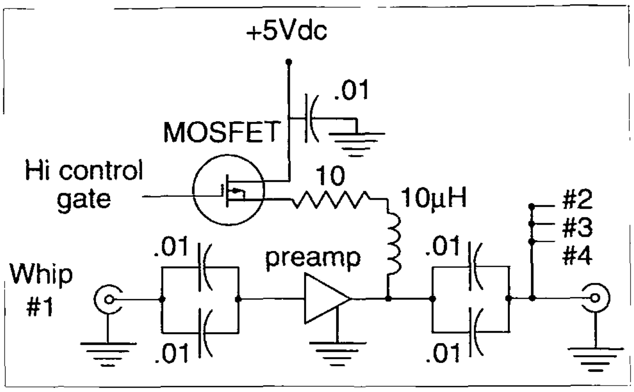

Figure 1. Schematic of the Doppler switcher/preamp designed by Jim Sorenson KA4IIA. All four preamps are identical, so only one is shown. All capacitors are surface-mount chip types.

to check over their antenna system very carefully. Then I recommend having another ham check to see if there is something they are consistently missing. Murphy must like Doppler arrays, because there are lots of ways to make mistakes in hooking up a switcher. Besides the usual shorts to ground and bad connections, I have seen units with reversed wiring of logic lines, two logic lines shorted to one another, failed PIN diodes due to overheating during soldering or accidental high-power transmissions, and incorrect placement of whips on the vehicle.

An oscilloscope is the best instrument for checking antenna set switching waveforms, but you can often find a failure or wiring error with just a digital voltmeter. To check your wideband Roanoke Doppler switcher quickly, verify the +3.5 VDC bias on the shell of each coax connector with respect to circuit ground. With pseudo-rotation turned on, the average DC voltages on the four whip rods should be within 50 millivolts of each other. Voltages at the inductors (L101-L104) should also be within 50 millivolts of each other. On the other hand, voltages on the center conductors of the four coaxes (between the series PIN diodes) may not be equal even on a working unit due to minor differences in diode leakage.

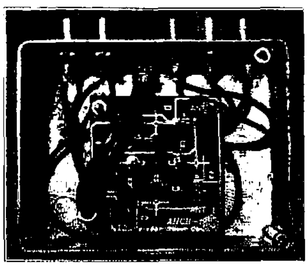

Photo B. KA4IIA's switcher is laid out on a 2-1/2 inch square board. The MOSFETs and RF chokes are visible. Monolithic amplifiers are on the other side.

I regularly check my Doppler's operation by taking bearings on a repeater atop Mount Baldy. One day I observed that the display did not track the repeater as usual. It just bounced around in one quadrant of the display, no matter which way the car was traveling. I checked the DC whip voltages and noticed that one was different from the others. Sure enough, a resistor lead in one antenna base was poorly soldered (oops!) and had lost contact, keeping the two PIN diodes in series with that whip from conducting. On another occasion, a voltage check caught a short from coax center conductor to shield at a whip base.

A Switcher With Gain

Over the years, Doppler users have looked for ways to overcome the inherent RF losses of antenna switching circuits. Jim Sorenson KA4IIA began experimenting with monolithic RF gain blocks from Mini-Circuits Laboratories in the antenna switcher of his Roanoke Doppler about six years ago. He found that these tiny preamps are manufactured to very close tolerances, so the signal phase shift through each of the four whip channels can be made nearly identical. This is very important because any difference in phase or time delay will adversely affect bearing accuracy.

Jim selected the MAR-4 amplifier, which has 8.2 dB specified gain in the 140 to 450 MHz range. Specified noise figure is 7 dB. Fig. 1 shows the schematic of KA4IIA's antenna switch, which has a separate monolithic preamplifier for each whip. Selection in sequence is done by keying each MAR-4 on and off with Zetex ZVP-4105A metal-oxide semiconductor field-effect transistors (MOSFETs), available from Digi-Key. Circuit layout must be done carefully such that path length through each of the four preamp channels is exactly equal. The best way to control path length is to use an etched board, as Jim did.

I was eager to compare Jim's antenna switcher against my wideband PIN diode switcher. I tested both in my T-hunt van and I also measured overall sensitivity of each on the bench with a calibrated VHF/UHF signal generator. I use a Regency MX-7000 continuous coverage scanner for receiving with my Dopplers, because I want to be able to perform RDF on any frequency from 120 to 500 MHz. It has 0.2 microvolts for 10 dB FM quieting sensitivity in this frequency range. That's more sensitive than many other scanners, but not nearly as good as most ham-band mobile and hand-held receivers of this decade.

When I fed the 146.565 MHz signal generator output though each of the two switchers (with rotation stopped), I discovered that the MX-7000 could detect a 7.6 dB weaker signal with the KA4IIA switcher than with the new Roanoke PIN switcher, for the same amount of quieting. This approximates the gain of the MAR-4 amplifier stage, with coax losses.

Does this mean that you can gain enough sensitivity to double your Doppler's range by simply changing from a PIN switcher to one with MAR preamps? Not necessarily. The receiver you use makes a big difference, as I found when I replaced the MX-7000 scanner with my IC-32AT hand-talkie and repeated the sensitivity measurements. The IC-32AT has a much "hotter" receiver, giving 10 dB quieting with only 0.125 microvolts at the antenna jack. With it, the Doppler sensitivity difference between the two switchers was only 2.3 dB. This makes sense when you realize that the noise figure of a MAR-4 preamp is not nearly as good as that of the IC-32AT front end.

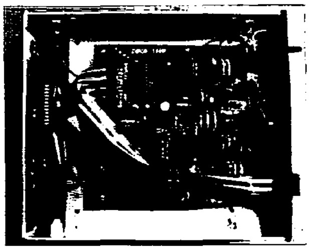

Photo C. Processing and display electronics are on separate boards in the Directional Systems Doppler unit.

In summary, changing to Jim's switcher circuit will give an overall sensitivity boost of 7 dB or so if the receiver in your Doppler setup is average. But the improvement will be much less if you're using a receiver with high sensitivity and an excellent noise figure with your Doppler. With a "hot" receiver, it may be difficult to tell the difference in sensitivity when T-hunting. My on-the-road experiments confirmed this.

Over the years, KA4IIA has built about two dozen antenna preamp/switchers for hams in his area, with help from Andy Glass WD4MYL, who helped test the circuit and write the documentation. Jim has formed his own company, Directional Systems, to distribute his Doppler products. They are popular with ham balloon trackers in the Atlanta area. According to KA4IIA, multipath isn't a big problem when the target signal is coming from a parachute payload thousands of feet in the air. "When it's above you, the Doppler just locks in solid," he says.

Jim's preamp/switcher covers the 2 meter, 125 cm and 70 cm bands, requiring whips of appropriate length and spacing for each band. In addition to the switcher (Photo B), he also sells a set of two circuit boards for Doppler processing and display, based on the Roanoke design. These high quality boards are double-sided with solder mask and silk-screen

markings for each component (Photo C). A matching enclosure is also available (Photo D). Depending on your home-brewing abilities, you can buy bare boards, board/parts kits, or fully assembled/tested Doppler sets from Directional Systems. Write to the address in the sidebar for prices.

Directional Systems kits and boards include detailed parts lists and assembly instructions. Completed units have a professional look. The biggest gripe I had after testing Jim's version of the Roanoke Doppler was that the direction-indicating LEDs are quite small. The front panel does not include the scan-stop switch and indicators for Low Signal and Overload, but they can be incorporated by drilling some more holes and adding the parts.

Keep the letters and e-mail coming with your experiences using all kinds of RDF equipment. I still occasionally experience short-term e-mail outages, so if you're expecting a reply and don't get one within two weeks, send your message again. E-mail goes to: Homingin@aol.com on Internet or 75236,2165 on CompuServe. Send postal mail to the address at the beginning of this article.

Complete plans for the basic Roanoke Doppler RDF set with single-band PIN diode antenna switcher are in *Transmitter Hunting—Radio Direction Finding Simplified* by Joe Moell KØOV and Tom Curlee WB6UZZ. This 323-page reference book (TAB/McGraw-Hill #2701) covers all aspects of RDF and is available from Radio Bookshop.

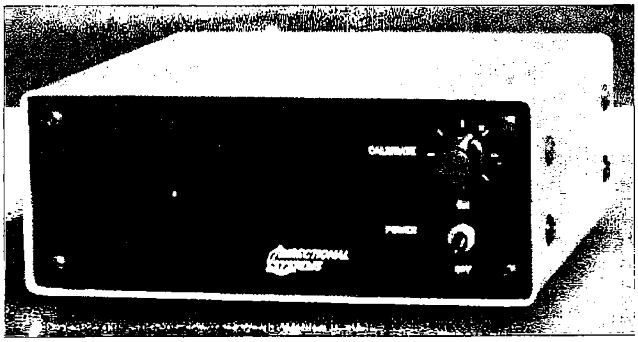

Photo D. The complete Directional Systems Doppler display is in a 7-1/2 x 6-1/2 x 2-1/2 inch enclosure.

Never Say Die

Continued from page 77

circuit from *Radio* magazine, which ran circles around *QST* in those days when it came to fun building projects. And we all built our own transmitters. Heck, we had to, since almost none were available commercially until well after WWII.

Hams originally built their own receivers, but then the day after the first commercial receiver came on the market, they stopped building them. I wasn't there when it happened, but it was about the time the National SW-3 arrived. Many hams I visited were still using the SW-3 in the late 1930s.

My first contact was with W2MSV, Dexter Miller. Dexter was mostly active on the 160m and was forever discussing which new receiver he was going to buy. But he couldn't make up his mind and eventually died without ever having enjoyed his dream. Dexter had a generous stomach and smoked, so he didn't make it much past his early 50s.

Yes, my first contact was made with me carrying my walkie-talkie, walking down the hill in Troy, New York.

Actually, I got my license almost by accident. I'd tried a couple of times, but through panic had failed the 13-per code test. Then a friend asked me to go along with him while he took the test. Why not? So I practiced my code for a few minutes the night before, but I didn't expect to pass, so I didn't bother looking at the Q&A manual.

My friend sat behind me during the test. I couldn't believe how easy the code test was! I had no problem copying it 100%, but that was because I'd expected to fail, so I wasn't tense or stressed. When it was over my friend had almost a blank paper. Yet the night before he was copying 15-per with no trouble. He never did get his ham license and we lost an excellent and creative engineer. He later opened a well-known audio laboratory in New York.

I was also active from the college dorms on 2-1/2m with a regenerative receiver I'd built and a pair of 76s with a long-line tank circuit. And on 160m with a T-125 final. Boy, did that raise Cain with the little AC/DC broadcast radios around the dorms. I had to operate mostly after midnight. Well, that's when you work the best DX on that band anyway. I won the 1941 Sweepstakes for my section just on 160m! And I was talking away on 160m on December 7th 1941 when I got word from a ham in western New York about Pearl Harbor. We were put off the air that same day, with W1AW chasing everyone off.

Well, Have You Read It Yet?

Several hundred *73* readers have read my book, *Declare War*. Alas, several thousand haven't…an egregious, inexcusable and disappointing oversight.

In it I propose a simple, inexpensive way to cut our American prison costs by at least 90%, while at the same time providing unlimited prison space and an actual re-education for the inmates. With 1.1 million Americans in prison, and at a cost of around $30,000 a year each, that's $33 billion going down the tubes just because we're too lazy to change our prison system. I also propose a painless way to cut the costs of our federal, state and local bureaucracies by 50% within three years. It's a bureaucracy that has a larger labor force today than is working in manufacturing. Then there's a novel way out of our welfare misery: a way to cut crime by at least 80%, and so on. I've been getting wonderful letters from people who've read the book. You know, I haven't had one letter yet saying my creative approaches to these currently insoluble problems won't work. They just want to know how come Clinton hasn't read the book. Or Perot.

This all started almost three years ago when Governor Gregg (now Senator Gregg) called and asked if I would serve on a New Hampshire Economic Development Commission. Since around 30 other businessmen and politicians had been tapped for the "honor," I explained that I would probably be more of a trouble-maker than the others combined. I was right.

It didn't take very many Commission meetings for me to discover that precious little would ever be accomplished with 30 people sitting around a big table. That meant that while one pontificated at length, 29 sat there not listening to what was being said because they were busy thinking about what they wanted to say, should they ever get a chance. Naturally we made zero progress.

So we split into subcommittees, each of which held hearings. I attended as many of these as I could and asked endless questions. The experts we invited in to testify did their best to explain their problems and failed solutions, and then gave me lists of books to read so I could learn more. I read 'em. I read a couple hundred books over the next two years, and I'm still at it in every available moment.

The Commission was formed because New Hampshire was suffering by far the worst of all 50 states from the recession. The Governor and the Legislature said they were looking for guidance, but they salted the Commission with enough politicians to eventually sink it without leaving a ripple…except for my reports. The Commission never even handed in a final report. The meetings just sort of quietly petered out.

Once I had a good grasp of the main problems facing New

Continued on page 87

Ham to Ham

Continued from page 60

another suggestion to make remembering Herb's tip easier: Make up a cardboard card with a schematic diagram and description of Herb's testing steps on it; epoxy a 470 ohm, 1/2 watt resistor to the card over the schematic's resistor symbol. Then when you next need to test an SCR, you'll have all of the info handy (and even the correct resistor!). I've used this method for other little test circuits that I use infrequently, and it's worked well for my not-always-perfect memory!

This ends another month of "Ham To Ham"...and our goal of keeping "Ham To Ham" viable for at least six months. Thanks to all who've submitted their tips, ideas, suggestions and operating procedures; you've made it work. Let's hear from more of you! The more input we have, the longer the column will go on and the more we can expand its scope. Let me hear from you at the address above; sending your suggestions and ideas to 73's offices in Peterborough only delays them since they have to be forwarded here.

We've all run into tips and shortcuts that we wish someone had told us about sooner; that's pretty much what we're looking for in "HTH." Don't be shy, send in anything that you think might have value to others in the hobby. If your writing skills aren't your strong point, don't worry, I'll rewrite your text so it conforms to the conversational style that I'm trying to maintain for "HTH." And be sure to look for a number of good new ideas here next month.

Note: The ideas and suggestions contributed to this column by its readers have not necessarily been tested by the column's moderator nor by the staff of *73* and thus no guarantee of operational success is implied. Always use your own best judgment before modifying any electronic item from the original equipment manufacturer's specifications. No responsibility is implied by the moderator or *73* for any equipment damage or malfunction resulting from information supplied in this column.

Please send all correspondence relating to this column to *73's* "Ham To Ham" column, c/o Dave Miller NZ9E, 7462 Lawler Avenue, Niles IL 60714-3108, USA. All contributions used in this column will be reimbursed by a contributor's fee of $10, which includes its exclusive use by *73*. We will attempt to respond to all legitimate contributors' ideas in a timely manner, but be sure to send all specific questions on any particular tip to the originator of the idea, not to this column's moderator nor to *73*. deDave NZ9E.

A Simple Capacity

Continued from page 72

If you used the specified colorburst crystal, chosen because it is the least expensive surplus crystal available, you have also constructed a signal source which produces known frequency harmonics in or near every ham band from 80 through 10 meters. For this "free signal generator" to be useful to you requires measuring the fundamental frequency with a frequency counter. This will *not* be the same 3.57955 frequency marked on the crystal!

Connect the frequency counter to J1 and J2, with R3 adjusted so its wiper is roughly centered in its range. Note the reading on the frequency counter. Using a calculator, multiply this frequency to determine the exact frequency of each useful harmonic. Keep this list for future reference.

A short piece of wire attached to J1 should allow you to hear the harmonics in your receiver. Because each frequency is accurately known, you can check dial accuracy or use the signals as an aid in alignment, or just tweaking for maximum gain.

Parts List

BT1	9V alkaline battery
C1, C3, C4, C6	0.01 µF disc ceramic capacitors
C2	10 µF 16V electrolytic capacitor
C5	220 pF polystyrene, mylar or dip mica capacitor
D1	Germanium diode: 1N34, 1N60, 1N90, 1N270
J1, J2	Binding post
M1	Meter, 100-300 µA full scale (see text)
R1, R2	560 ohm 1/4W 5% resistor
R3	Carbon potentiometer, 200 to 300 Ohms
R4	1K 1/4W 5% resistor
S1	SPST toggle or slide switch
U1	74LSOO
U2	78LO5
Y1	3.57955 MHz crystal (see text)

A Stealth 40-10 Meter

Continued from page 55

want, but, since you'll be using a tuner so you can use several ham bands, the wire length isn't particularly important.

It 's better to operate from a room other than the one in which your antenna is installed. Why expose yourself to RF if you don't have to? (But this isn't very important if you're running under 50 watts.)

Disclaimer: This antenna may not work well if you have a metal roof (maybe try loading the roof as an antenna); or there is metal mesh holding the stucco on the outer wall; or a metal heating or air conditioning duct runs above the ceiling near your antenna; or Murphy got there first.

Ask Kaboom

Continued from page 78

If the power light comes on and the fuse doesn't blow, but you still don't get a picture when you connect a computer, take a look at the back of the picture tube. If you don't see an orange glow from the filaments, they aren't lighting. Many are driven by the horizontal output circuit, via a fast-recovery rectifier. This is a special part, and an ordinary 1N4000-type part won't work. I recently ran into this problem, and replacing the diode brought the set to life.

Hopefully, your monitor is now fixed. If not, you've got a standard troubleshooting job ahead of you. If the set seems dead, check specifically for activity in the horizontal oscillator circuit; no signal, no high voltage and no picture! On many sets, even the power light is driven from this circuit, and that's a valuable clue. If the power light is on, the horizontal is running! Some sets, though, drive the light from the switching power supply, so follow the wires back to the board to be sure.

Set 'Em Up

Once you get your monitor working, you'll want to adjust it for the best picture. Next time, we'll explore how to set up the focus, screen level and color balance. Until next time, 73 from KB1UM.

Communications

Continued from page 70

and then at the receiver convert it back to the audio or video signal with a *digital-to-analog converter*. This method is currently used in compact discs, in digital audio (such as the WAV files in computers), and in digital radio. It is also now used in telephone systems, for sending voice signals through fiber optic cables, and for an entirely new telephone system called ISDN or the Integrated Services Digital Network. ISDN will eventually provide direct digital connections to your home, which can be used not just for phoning your friends, but also for sending digital data and pictures.

BARC Jr.

by Ben Fenster KBØOVM

What is BARC Jr.? It's the Boulder Amateur Radio Club Junior. Founded in 1993, it is a club for kids under age 18. Today, three years later, it is a club with more than 40 kids ranging in age from 6 to 16. Its purpose is to get more young people into ham radio. This is done by demonstrations, participating in Field Day, and so on. At swapfests, BARC Jr. sells J-pole antennas made by the members, plus donated items, and uses the money to buy kits for the kids to build, buying loaner equipment, funding social events, and most of all, funding an annual Dayton HamVention trip. Every year one member is sent to participate in the Youth Forum. Besides this, there's a class every week where they study the code, have a technical session, and witness a demonstration. BARC Jr.'s 15-20 Elmers teach the Novice through General classes. At some classes operating procedures are covered, such as how to use and what can be said on an autopatch. Once a month a speaker comes in to talk on anything from antennas to repeaters to autopatches. And every Sunday the group gets together on the 146.700 BARC repeater.

We occasionally take field trips to participate in contests or see repeater sites. Once we took a trip to the Big Horn museum in Byers to see old radio equipment. Around Christmas we have a party, every August we have a family picnic and foxhunt, and now and then we have a group dinner.

We also have red BARC Jr. T-shirts, hats and pins, and various other things are sure to come up soon. As you can see, BARC Jr. is a well-identified club.

This year at Field Day we had a visitor. Wayne Green was in the area and stopped to see our Field Day activities, and asked for an article about BARC Jr. I am the editor of "Yip Yap" (the BARC Jr. section in BARC Sr.'s newsletter), so I was given the job, and here is the finished product.

Kelly Woo KE6KJU was featured in the cover picture for the July 1995 Radio Fun which had an interesting article on page 12 written by KN6MG about her. Kelly convinced her dad, KN6MG, that she wanted to get her ham license. Kelly dropped by the 73 booth on the Queen Mary and had her picture taken with W2NSD/1. The article is in Radio Fun #47 and is available postpaid for $4 from Radio Book Shop (order form on page 88.)

QSL Contest

Did you buy your QSL off a rack,
or did you put some thought
and creativity into it?
If you think you have a winner,
send it in and let us have
a look at it. Who knows, it might make the cover.
Well, maybe page 85 or so.Or maybe Wayne's wastebasket.
If it's declared a winner, you'll get a CD
of your choice of any of 26 kinds of music, as listed in Wayne's
November editorial. You'll also see it in 73! Send it to
QSLContest, 73 Magazine,
70 N202, Peterborough NH 03458-1107.
Bribery?
You Bet!

Dots and Dashes

Hal Goodman W3UWH
Box 942
Bala Cynwyd PA 19004

As I think back over the nearly fifty years I have spent as a ham, few things seem as thrilling as my first few CW contacts on 80 meters. My very first contact was with a ham who lived only two blocks away. I had made arrangements with him at the local radio club meeting as to time and frequency. I only had one crystal, so picking the frequency was easy. As the time approached, I plugged the eighty meter coil into my three-tube super-regenerative receiver and turned the power on to my two-tube (rectifier and oscillator) transmitter. My transmission was only at about four or five words a minute and filled with many errors. However, he was very patient and I was able to complete the contact.

Today, I frequently tune the eighty meter Novice frequencies and really enjoy helping some youngster feel the thrill of making a CW contact. Even though many people today say that CW is obsolete and should no longer be required, it is an accomplishment. After all, being able to communicate by CW is something that 99.965% of the world's population cannot do. And, besides it's fun.

I was talking with a youngster recently who told me he had just gotten his ticket and that I was his third contact. He asked how long I had been on the air and when I told him, he asked what class license I held. When I told him that I was an Extra Class, you could almost hear the excitement as he asked if that meant he could send faster. When I said yes, he started sending faster, though the first thing he said was, "Don't you send faster."

However, there is a down side for us old timers when it comes to working today's new hams. Our reflexes are not as fast as they used to be. You might ask, what do reflexes have to do with copying CW? It's not the copying, it's the trying to make sense out of what you are copying quickly enough to understand what is being said. Most youngsters are in too much of a hurry to build their code speed up to where they can pass the code test, and then never have to use code again. They are not willing to put in the time and effort to develop a "good fist." Instead, they get an electronic keyer, thinking it will make up for their lack of skill.

> ***"Relax, there is nothing more enjoyable for most of us "old timers" than joining in the excitement a new ham experiencing the joys of ham radio."***

Unfortunately, it only makes matters worse. Let me give you an example. About two weeks ago, I made contact with a Tech-plus op. I looked him up later and found his name was Bill. What follows is an exact transcript of what I copied. Only the call sign is omitted to protect the guilty.

"W3VWH/lt di N2— fb om dami is 6anl. buel. qt5 is roc5ehtil, ny rochismir, ny ur rht 58e9e rsm 5891, ho bx tu 6k"

No, I'm not kidding. That is exactly what I copied. I may be getting senile, but I can still copy ten words per minute accurately. He was using one of those electronic keyers without knowing how to use it. The key speed must have been set for at least 25 words per minute. Now had I been younger and had faster reflexes I might have been able to ignore the extra dots and occasional extra dashes. As it was, he seemed to have turned it back to me and I was sitting there looking at what might as well have been hieroglyphics. What do you answer? 'N2— de W3UWH/1 severe lightening, must QRT immediately, 73 de W3UWH/1."

Back in the old days, when you took your code test you had to both copy and demonstrate your ability to send code. Speaking for us senior hams, arthritis and all, I think we should reinstate that requirement. Let those who don't want to do code content themselves with no-code Tech licenses or type their messages on the Internet.

Another area of CW communications that is becoming lost, is the ability to use the English language. Now don't get me wrong, I have no objection to, "fb om es tnx for the qso." It's when the messages start to look like, "tnx it wznce of u to ans my cl, sd cpy. rghr knwd to a bazk up 40f, rn 70wts." Yes, I know we can all take a minute and figure out what was sent. But the purpose, for me at least, in making a CW contact is to enjoy the experience, not a test of cryptography skills. It seems that the current crop of new hams is laboring under the misconception that if they don't abbreviate absolutely everything, they will look foolish. It reminds me of the time when as a youngster, before my voice changed, I would practice trying to talk in a deep voice, because I wrongly believed that no "old timer" would talk to me if he thought I was a kid.

Relax, there is nothing more enjoyable for most of us "old timers" than joining in the excitement a new ham experiencing the joys of ham radio. Most of us are retired or at least have lots of spare time and you don't need to rush. Take your time, develop a "good fist," and only use common radio abbreviations. If you do that, then there will be no "generation gap" within the ham fraternity. 73

HAM HELP

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full 8 1/2" x 11" sheet of paper. Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

Can anyone supply me with an operating manual and schematic for a **PAL 200 MDX** 12 volt mobile Linear Amplifier? I will pay a reasonable amount for photocopies and postage. *Al Cikas KA9GDL, 412 Radford Dr., Sherman IL 62684.*

During the past year I have received about a dozen QSL cards stating that the operator copied my call (WN8F) as QSL manager for Paul 9L1PG, from Sierra Leone. In most cases, I have returned the cards stating that there must be a misunderstanding of the call, as I am not, nor have I ever been a QSL manager. I know this is a disappointment for these operators and trust the correct QSL manager for 9L1PG can be copied correctly in the future. *Ken Massie WN8F, 115 Woodlawn Dr., Ironton OH 45638-2355* 73

NEVER SAY DIE

Continued from page 82

Hampshire and America, I tackled each of them and came up with a creative solutions based on things I'd read about or seen working in other countries. Being an entrepreneur, my proposals were for ways to solve problems spending the least amount of money, and for ways to cut our taxes and reduce government. You see, I have this crazy idea that the government should be working for us instead of us for them. It'll never sell, I know.

Instead of trying to break through the endless talkers (though saying little) on the Commission with my ideas, I decided to write reports of what I'd discovered and present my proposed solutions that way. Several of the Commission members were very enthusiastic about my reports, while others said nothing. When I met or called those I hadn't heard from and asked what they thought, they said that golly, they really hadn't had a chance to read my reports yet. They still haven't, as far as I know.

I've reprinted my reports in a book and I'd like to have you read it and start sewing the seeds of my ideas all around the country. The book runs 360 pages and I think you'll find it fun to read. Yes, I do fulminate about the damned Commission members and their inactivity. Heck, half of them dropped out in the first few months, after having contributed little, if anything.

The book has been selling in New Hampshire book stores for $13, or from Uncle Wayne's for $16, including shipping. I'll tell you what, I want you to enjoy the book, so while they last you can get one for $13 postpaid. Further, if you are in any way disappointed, send it back for $13 credit toward anything else Uncle Wayne's Bookshelf has in stock. You can't lose, and you could win big. And so could our country.

The proposals I've made to help New Hampshire are just as applicable to any other state.

20/20 Foresight

After reprinting the first year of my reports in the book I couldn't keep myself from continuing even more reports. 21 of 'em before I slowed down. I should put these into a book too, and probably will, eventually. These reports are packed with more ideas for businesses. How about a way for us to double or triple our foreign aid, but instead of giving the money away to despots who don't even thank us, how about making a huge profit on every aid dollar we spend? You're going to love my proposals. I've written extensively on solutions to our school problems, and on health. While copies last, $10 for the 336 pages.

Payson AZ 85541

This month is expected to provide some excellent DX on the HF bands. Good days are distributed throughout the month as shown on the chart, but the Poor days are concentrated around the 4th, 15th and 22nd–25th. The remainder will be Fair or trending. You may also find some geophysical effects on earth and in the ionosphere around the 23rd or 24th.

It appears that Cycle 22 is bottoming out as you read this, and Cycle 23 has already begun. Although it will take a while for solar flux levels to increase significantly, the trend is upward...and rise time of a cycle is faster than decay time...so rejoice!

10–12 Meters

Occasional trans-equatorial F-2 layer openings during daylight hours, with 12 meters to show greater signal strengths.

15–17 Meters

Circuits from the Northern Hemisphere to Africa and South America should open on Good days, and daytime short-skip openings will also be present on Good days. Performance of these bands will be sporadic, but on some days will sparkle.

Where 10 meters is shown, also check 12 meters. Where 15 meters is shown, check 17 meters too. Where 20 meters is shown, be sure to look at 17 as well. Always check the bands above and below the indicated bands for possible openings to the areas shown. Remember that DX is where you find it, and not always where it is predicted to be.

31 G						

20 Meters

This will be your most consistent band of choice for DX opportunities from sunrise until after sunset. Expect DX from Northern to Southern Hemispheres with decent signal strengths on most days, and short-skip openings to 2,000 miles as well.

30–40 Meters

DX from just before sunset until shortly after sunrise will provide enjoyment on the Good days. However, be aware of seasonal QRN interfering with weak signals. Signals peak to the east before midnight and peak to the west before dawn. Daytime short-skip will be good out to 1,000 miles or so.

80 and 160 Meters

DX during hours of darkness will be available, but not as prevalent as during the winter months. QRN may become a problem for weak signal reception. Some daylight short-skip on 80 will be present, but none at all on 160. 73

Priorities

A letter from a reader who is embroiled in a pissing contest with a crusty old ham asked my advice on how to handle the situation. Though he will probably ignore me, being caught up in the emotions of his windmill tilt, I suggested it was time for him to sit down quietly somewhere and think over his priorities. With spring here…a time of awakening and renewal…maybe you could do worse than shut the shack door, turn off the rig, and spend some time thinking.

What do you want to do with your life? What goals have you in life? Do you hunger for recognition and honors? Money? Do you have a need to leave the world a little better for your having been here? How about your children? They are one of the best investments you can make for posterity, unless you neglect them in pursuit of short range goals. Is your family being fed right so they'll be able to live long, healthy, and productive lives? Do you even know what they should be eating? How much have you read about that?

Sure, amateur radio is fun. But so are computer games, playing chess, going to the movies and bowling. There are an almost infinite number of ways to have fun that do little or nothing to help you or your family to grow. I've used amateur radio as a way of learning as well as entertainment. It got me to go to a tech college, then into the Navy as an electronic technician, where the school was superb. But i didn't get on the air and vegetate. I was quickly experimenting with VHFs. My first ham contact was with a 2-1/2m walkie-talkie I built from an article in *Radio*. Then I discovered RTTY and helped put an RTTY repeater on top of a NYC skyscraper in 1949. The next thing you know I was doing an RTTY newsletter, then a magazine on the subject. When NBFM was invented I was one of the first using it in 1946. And so it went with SSB in 1954, SSTV in 1968, my own repeater in 1969, and so on. I've never vegetated in ham radio.

Give your life some thought and try to take a long range look at it. What can you accomplish with the time you have left? Is being just another cog in the wheel enough? Do you really want to spend your life on petty quarrels with idiots? If so, why not get into politics?

In my editorials I've been trying to get you to open your horizons. To read, learn, understand the world, and help me move it ahead. I feel I've been successful in pursuing my goals. I've helped just a little to bring the world cellular telephones, computers, and better music. Now it's cold fusion, which will be the greatest gift I'll ever be able to give the world by far. Sure, all of these things would have happened without me, I'm sure. But my minuscule pressure has helped. No, I haven't gotten many honors. But I haven't hungered for 'em. No "Ham of the Year." Etc. But I have helped thousands of my readers to have better lives, and I don't think I've caused anybody to have poorer lives for having read my magazines or even for having worked for me.

With the millennium coming in four years, why not take a few minutes to re-focus your life. Think about your wife. Your kids. What can you do that will make life better for them? How about your business or the people you work for? What can you do or study that will help them and you? What new skills can you build? Are you working at a job that is more fun than work? So why not? Is it worth your time and effort to learn about nutrition so you and your family can live to 150 and be healthy and productive every day of your lives? Are you using amateur radio as a way to have fun while you are learning? Or are you a vegetating curmudgeon? Is working a new country more important than helping your children to grow? Is that 75m net more important than taking your wife out to dinner and a movie? Or maybe planning a surprise trip somewhere for a weekend?

Are you stuck up on some 2m repeater for life? I feel so sorry for the no-coders who are not using the key to fun and education they have in their hand. No, not the CW key, it's the key to packet, satellites, slow scan, and so on. I feel sorry for the thousands of hams living out their remaining days on 75m nets, or fighting pileups and queuing up for DX lists. Amateur radio should be a key to fun and education, not an end in itself. Lift your eyes from this page and stare out the window. It's a big world out there and it's in desperate need of help. Help *you* could provide.

Our school system is awful because you let it get that way. Ditto our medical industry. And crime, drugs, and so on. When people work for me one of the first lessons is to erase the whole concept of "that's not my job." The bad language on our bands *is* your job. The Techs stuck up on 2m because no one has pushed them to upgrade *is* your job.

Small business is the real power of America, not the *Fortune* 500 giant business cartels you've meekly let get control. With the help of Limbaugh we've started flushing the crap out of Congress, but if you re-elect any incumbents you're partly responsible for the proliferation of drugs, crime, the bulging bureaucracy, and so on. Never Re-elect Anyone (NRA) is my bumper-sticker slogan. Get those greedy old Byrds out of congress.

LETTERS

From the Ham Shack

Klaus Wolter N8NXF. Wayne, what's this noise I read in your editorial about a motor/generator perpetual motion machine? I doubt there is any magic involved. I have not looked at the patent but will poke a guess. You mentioned that this motor/generator claims an input power of 19.55 watts to run as a motor and that the generator puts out 62.16 watts. I'm sure it can, but I'll bet you it can't do it at the same time! I bet the electric vehicle (scooter) you rode was powered by a battery whenever it required energy to accelerate, chug up a hill, or maintain speed. When it is time to slow down or come to a stop, the motor controller dumped that energy by running the motor as a generator and recharging the battery. This is nothing new in EV circles and is commonly used. It's called regenerative braking. A net excess of energy however cannot be produced by such a system. The high density magnet Takahashi developed, among other things, can make for smaller monor/generators. A problem with regenerative systems is that it is possible to demagnetize the magnets in the motor if one tries to generate too much power while running it as a generator. These magnets seem to be more immune to this when I consider the generator output/motor input ratio. I enjoy your editorials. Keep it up! *(Klaus, I'm suspicious of any claimed over-unity devices, so I'll be watching to see where the catch is. With the cold fusion effect now seemingly coming from the transmutation of elements within the metal lattice rather than zero-point energy or any other over-unity systems, it seems on firmer ground. Wayne)*

Marion Kitchens K4GOK. I do enjoy your editorials. And I agree with about 95% of your ideas, thoughts, comments. As a professional working for your government, I use many of the same techniques you do when trying to get people to use their brains! It is sometimes a real challenge, sad to say. Anyway, don't let up -keep on keeping on. There was a delightful change in the February issue of the magazine, specifically on the "Table of Contents" page. No, I did *Not* read that part about "The merest glance.......... Not me — no way will I enter a contract like that! Ha, Ha, Ha! Seriously, it is good to see the perky, humor shown therein. Maybe that means a positive, energetic bunch around the editors' desks. I hope that is the case.

Give the article by W6IOJ a "G" rating. It brings back some of the things I think are important to, but missing from, our hobby. Namely, showing people how to achieve good, positive results by hands-on experience with easy, simple techniques. In my humble opinion, that is a great article. See if you can find more like it for future issues. I for one, will read 'em all. *(Thanks! And congratulations on only being wrong 5% of the time. Wayne)*

John Clark KA2ZPM. Many hams with cataracts or whatnot will appreciate your almost total conversion to Roman type and the leading. Good job on the January issue. Wish you many ads in '96. *(Tests have always shown that serif-style type (such as Times-Roman) are much easier to read than sans-serif type. And that increases the comprehension and retention of the material. But artists, who are unconcerned with type readability, prefer the more beautiful sans-serif type (such as Helvetica). Anyway, glad you approve. Now, if we can only get our photo scans to look better! One more thing. I'll have to write about this, but according to Dr. Wallach, who is a Nobel nominee, cataracts are purely a mineral deficiency disease. If you get the minerals your body needs your eyes will do just fine. Wayne)*

Arthur Harris KC6WZJ. It appears to me that you are overlooking an excellent business opportunity. As you close down *Radio Fun* you should start a new magazine called *No Code*. In fact you should close down 73 also, since the numbers indicate that 73 is aimed at a minority audience. The new magazine would encourage the no-code majority to form their own radio clubs and pursue their own agenda. Of course, the first two things on that agenda would be to petition the FCC to eliminate the code requirement in amateur licenses and the other would be to recognize that the keypounders are **the enemy**. Their interests are not our interests. Lest the keypounders get upset, they should remember it is their mandate that puts the majority of amateurs in the back of the bus. Us po' no-codes just gettin' tired of the small back of the bus with all you minority folks up in the big front of the bus. Maybe its time for a little affirmative action.

You get many club newsletters. How many conduct code classes? I have visited a few and none gave code classes. Theory but no-code! If code was God's gift to mankind, as asserted by the keypounders, it seems to me that they would be falling all over themselves to give classes and enlighten the po' unwashed no-coders.

Sitting here in the back of the bus, gazing forward to the keypounders and especially towards those Big Daddy 20 wpm types, I'm struck with an observation. How come these people will talk on HF with foreign no-code amateurs, but will not do the same for American no-code amateurs? Talk about bogus! I guess honest keypounder is an oxymoron after all. The majority of material in 73 deals with areas which are forbidden to me as a no-code amateur, thus I wouldn't dare comment, lest it offend my betters. I'll give "Kill Your Interference" at least 10 G's. *(Art, I have so many economic opportunities I don't know which way to turn. I could have turned Radio Fun into a no-code rag and made big bucks. I think CQ is doing that. But then their editor is still a Tech. after all these years. But shame on you for fanning the flames of religious intolerance, the code being a religious matter, not one of reason. While I think the code test is a stupid hangover from antiquity, I have no sympathy with anyone who is too lazy to learn it. If they use my method almost anyone can learn to copy 13 or 20 wpm in a few days. Or you can use the ARRL and other systems and take a year or so of frustration and sweat. I went that route, so I know how awful it is. The few clubs that have code classes are teaching to old slow system, so stop fussing about that. You don't need a club, all you need is a couple of my code tapes and the gumption to actually use them for a few hours. Tens of thousands of hams have used my method and zipped right through, so don't come whining and sniveling to me about how the code is an obstacle ... Wayne)*

Bed Hodgins, Riverton NJ. First some background information about myself. I'm sixteen years old and I'm a sophomore in high school. I don't have a ticket yet, but I sure would like one.

Just a few thoughts before I say what I'm really writing for. I don't have a subscription to any ham radio magazines. About the only time I get one is when I have a few extra dollars in my pocket. I invariably get 73 because I enjoy reading your columns. So much of what you say needs to be said more often. Especially in the December's issue. Your view on the minimum wage is right on. You are the only person that I know of who's saying those things. Hopefully your words on that subject will show a few people "the light."

What I really wanted to write about concerns the issue of recruiting new hams. It seems that the hobby is losing more hams than it is replacing. This is something that you are concerned about. I've been very interested in ham radio for five years now. Part of the reason I haven't gotten my ticket yet is that I haven't found a VE to give me the test. But that is only part of the reason. At first I was scared of the code. I'd spent time trying to learn it, and never succeeded. When the FCC announced the no-code Technician license, I decided to go that route until I could conquer the code. The other reason I've not taken the step is my lack of a mentor. You see, unlike all these young kids and who have hams in their family going all the way back to Tesla, my father is not interested in ham radio. If I do happen to get my license and maybe some day a radio, he'd be glad for me, but he's not going to go too far out of his way for me.

One of the remedies to my first problem (the code) is your solution—"To he— with the code." Another of the remedies is for older, more experienced hams to take a greater interest in recruiting new hams. Most newspapers have a section that lists community events. It would take all of ten minutes to call

FleaSpeak 101

With Dayton and a host of smaller hamfests coming up this spring we thought it might be a good idea to brush up your vocabulary so that you understand what those well-meaning hams on the other side of the flea market table are saying. Here is a translation guide that we pulled off a USENET amateur radio news group.

"This rig puts out a BIG signal!" (The rig flat-tops and distorts so badly, your signal will be at least 50 kHz wide!)

"This rig will bring back the feelings and atmosphere of vintage ham gear." (The bypass capacitors to the AC line put enough voltage on the chassis to give you a shock in the lips through the microphone, and it smokes so much when you turn it on that you'll probably start coughing and wheezing.)

"The transmitter is outstanding." (It doesn't receive.)

"I just aligned it." (All the slugs on the transformers are now snugged down tight.)

"This is the rig of my dreams. I really wanted one of these as a kid, but now (snuffle) I've got to let it go." (As I've gotten older, I've learned what a hunka junk it is.)

"It worked last time I used it." (And if it still worked I'd still be using it.)

"Real popular rig in its day." (Yeah, there were whole HF nets on the repair and maintenance problems.)

"I'll help you carry it to the car." (I'll do anything to unload this boat anchor.)

TNX to Dave W9GR and all the others that contributed to this post.

Tampa Museum Pays Off!

Robert and Janice Miller and their two sons, Frank and James, visited the Museum of Science and Industry in Tampa FL about two years ago. Everett Hale KA4IZQ showed them what ham radio was all about at KE4ZRS, the museum amateur radio station. The Millers, from La Belle FL, were so impressed that they decided to become ham radio operators. Within two years Robert obtained his Advanced Class license, his 16-year old son Frank got his Extra Class ticket (AD4RD), his 14-year old son James got his Advanced Class ticket (KE4PQH), and his wife Janice got her no-code Tech ticket (KD4ZIX). Have any other museum stations won us converts? No reports of such, so presumably not. TNX Clark Evans WA4DLL for the news.

Another Milestone

Larry N8GZW and JoAnn Brauneller of Ohio celebrated their 35th wedding anniversary October 22, 1995. Adding to the festivities was Keith Berning KCØWL, who presented his parents-in-law with a commemorative copy of *73*'s 35th Anniversary issue. Congratulations from all of us to this ham family! (Photo by Keith Berning KCØWL.)

What a place to blow a fuse

German cosmonaut Thomas Reiter DF4TR/DPØMIR, aboard the Mir orbital complex, reports that a power supply used for some of the spacecraft's ham radio equipment failed on New Year's Eve. The remaining older power supply is only capable of powering the old Icom 2-meter transceiver and one 1200-baud TNC. The digital voice module also has failed, so there will be no more automatic voice recordings in the near future. Reiter reports all four fuses in the two connected transceivers have blown and only two spare fuses remain. Last month, Reiter used the digital voice recorder, built by Thomas Kieselbach DL2MDE to broadcast holiday messages. The primary transmitting frequency is 145.800 MHz. Recently, the cosmonauts on Mir unpacked new amateur radio equipment delivered by rocket, including a 70-cm FM transceiver and 9600-baud packet gear. Reiter was philosophical. "Well, at least we can be reached and still can talk with the world," he said in a message to Dave Larsen N6JLH.

TNX W1AW bulletin ARLS001

How's Your FIST?

Just got your Novice or Tech-Plus and want to give CW a try? (After all, you did put all those hours into code tapes and they say the best way to build up speed for that General is on the air.) Check out FISTS CW Club. Our Tech Editor N1VXW after a very long CW QSO with Ken Coughlin KF8RG was sent a QSL and an application to FISTS. The CW club is the membership organization of the International Morse Preservation Society, a club dedicated to keeping CW alive, well and fun on the amateur bands. While Morse may not be everyone's cup of tea, FISTS is dedicated to helping Morse be a pleasurable experience for those inclined to try it.

FIST organizes high and low speed nets on a weekly schedule, provides QSL Bureau services and there's even a number you can call to "Dial-A-Sked" so you can make that first CW contact less nerve-racking. The organization was founded in England in 1987 and has a North American branch. If you're a newbie to CW or have been pounding brass for longer than you can remember it just might behoove you to get in touch with Nancy WZ8C, the North American Representative of FISTS. She can be reached at: PO Box 47, Hadley MI 48440-0047, (e-mail 73631.3654@compuserve.com).

440 Super J-Pole Antenna

Here's a great club project!

Marty Gammel KAØNAN
1703 Hewitt Avenue West
St. Paul MN 55104-1128

Why pay commercial prices for a UHF antenna you can build at a fraction of the cost? Here's a great antenna you can build for less than $7 (at current prices). Even better, once you have all the materials in hand, it should slip together in less than an hour. Then you can brag that you "made it yourself!"

"They have almost 6 dB of omnidirectional gain, and don't have that crummy lobe shooting up toward passing aircraft that a well-known commercial antenna suffers."

I love J-pole antennas for the VHF and UHF bands. They have almost 6 dB of omnidirectional gain, and don't have that crummy lobe shooting up toward passing aircraft that a well-known commercial antenna suffers. They consist of a vertical quarter-wave antenna, with a half-wave mounted above it to provide gain by concentrating the radiation in a narrow vertical lobe.

Building the antenna

First, clean the areas of the tubing that will be soldered. Use a scrubbing pad or fine emery paper to get good, long lasting solder joints, since clean mating surfaces are very important. Clean the 3/16" tubing at this time, too. Clean *all* the copper with a solvent such as lacquer thinner or acetone and a rag, and do it in a *well ventilated* area. You don't want to inhale any of that stuff!

Lay all the half-inch copper sections out and apply flux to each piece to be soldered. I use a paste flux and apply it to the tubing, giving a twist as I assemble each piece to the next one to spread the flux around the whole joint. It helps to set a weight across the 19" and 6" pieces to keep them parallel during the soldering process. Measure the distance between these at the top and bottom of the 6" section to make sure that they are equally spaced. This is the tuning section of the antenna. Be generous with the flux; it helps clean the surfaces, as well as helping solder flow with less overheating and discoloring of the copper tubing. Any excess flux can be cleaned up using a rag and solvent after the soldering is complete.

Install the 12" wood dowel insulator between the upper and lower vertical sections. Form the 1-1/8" by 2-1/4" piece of sheet metal to make a heat shield to avoid burning the dowel. Next, drill a 3/16" hole about 1/8" in from the upper end of the lower section of the half-inch copper tubing and dowel, and do the same with one end of the upper vertical section of the copper tubing and the dowel. Bend the 3/16" tubing to form a very tall "U" shape and insert the ends into the holes you have just drilled.

You can start soldering at either the elbow or the threaded fitting, heating the copper ahead of the torch by allowing the angle of the flame to preheat the next joint. Solder all the lower joints and the "U" matching section first. Allow these to cool before you solder on the end caps. After the copper has completely cooled, clean the flux off all the solder joints using solvent and a rag or paper towel. Then, with a clean rag and solvent, completely clean the entire antenna. Once the solvent has evaporated, spray at least two coats of an exterior clear finish on all the surfaces of the antenna to keep it looking new.

Apply caulking or silicone to the dowel insulator and wrap this area with electrician's tape. It won't hurt to apply a coat of the exterior finish to further seal this area.

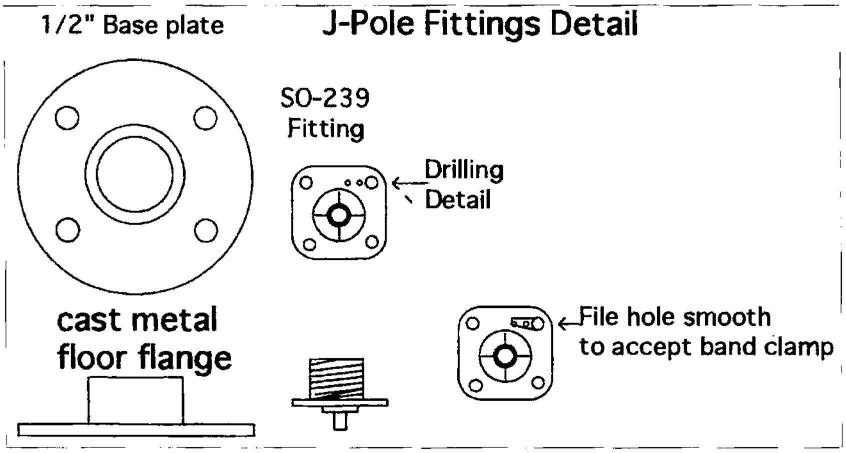

Fig. 1. Construction details.

Now we're ready to work on the coax feeder. The two hose clamps will be clamped to the pipes about 2-1/2" above the bottom crossbar. One will be screwed to the SO-239 flange and the other to the center connection, via the short piece of #16 wire. You'll probably have to drill a special hole to screw the SO-239 flange to the hose clamp. Now strip about 3/8" of the insulation from one end of the stranded #16 wire. Solder one end to the center hole of the SO-239 and the other to the clamp on the long vertical section of the antenna.

Tuning the antenna

Clamp the base plate to a stepladder or a railing away from close objects. Be sure your SWR bridge is capable of measuring at 450 MHz. Using low power, start by measuring SWR at the top, middle, and bottom of the band. The 2-1/2" feed point height above the crossbar should be very close. Move the feed point by sliding both clamps only 1/16" up or down. Try to find your best SWR on the repeater input part of the band, if that is where you plan to use the antenna. Using this design you should have an SWR below 1.5 over the band.

Parts List

Type M 1/2" copper tubing, cut to the following lengths:
19" (1)
12" (1)
6" (1)
1-3/4" (2)
13" of 3/16" copper tubing
1 1/2" copper elbow fitting
1 1/2" copper "T" fitting
2 1/2" copper end caps
1 1/2" copper threaded fitting
12" length of 1/2" birch dowel (for insulation)
1 SO-239 fitting
1 short piece of #16 stranded wire
2 5/16" x 7/8" stainless steel hose clamps
1 1/2" cast metal floor flange
Spray-on exterior clear finish
Plumber's tubing cutter
Electric drill and bits, 3/32" and 3/16"
Propane torch, solder and paste flux
Screwdriver
Electrical tape
Solvent and scrubbing pad (or steel wool or emery paper)
Caulking or silicone
1-1/8" x 2-1/4" sheet metal soldering shield
Drill press, small file (both optional)

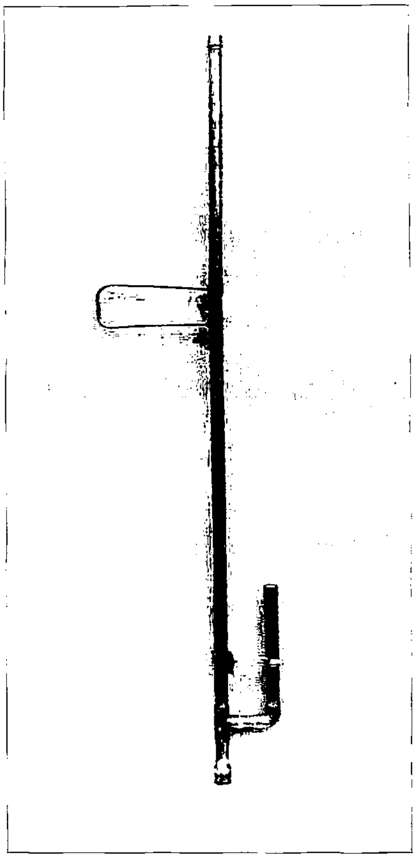

***Photo A.** The completed 440 Super J-pole.*

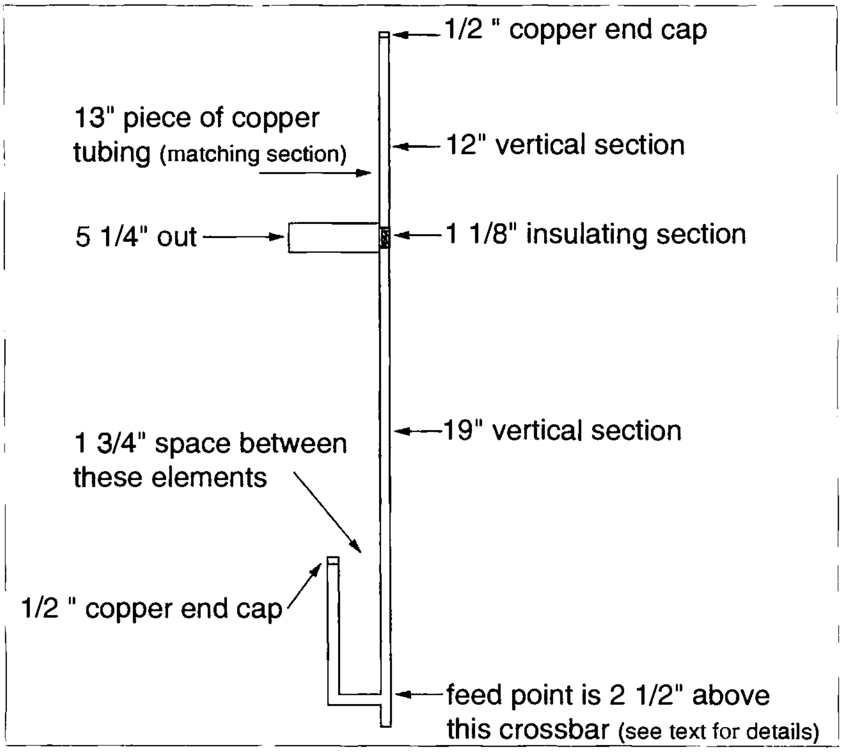

***Fig. 2.** J-pole fittings detail.*

Tighten the feed point clamps, apply a coat of silicone to the back of the SO-239, and then spray a coat of exterior finish on the tuned feed point to seal out the weather. Tape the feed point connection to the coax, and also tape the feedline to your mast every two or three feet to make a neat, long-lasting, trouble-free installation.

Note

If you want even more gain you can add two more vertical half-wave sections, along with a horizontal matching section for each of them, using more birch dowel insulating sections. Place each matching section 120° from the section below it (otherwise you may distort the omnidirectional radiation pattern). This gave me three vertical half-wave sections above the typical J-pole design of a vertical half wave driven by the quarter-wave tuning section below it. Field strength tests showed that there was a 50% increase by adding the two vertical sections.

If you have any questions just send a #10 SASE to my home address above.

The Hentenna

An easy construction project and a chance to experiment.

L. Scott Hall KAØDAQ
3001 8 St. N.
Saint Cloud MN 56303
LScottH@aol.com

Don't you just hate it when antenna articles tell you how great the antenna is and then leave out some important piece of information? This happened with the hentenna. I've only seen two articles on it, one in QST (Feb. '82) and the other in Antenna-X (May '89). They both described its history and wonderful performance, but gave only the vaguest indication where the feed point should be. I had clipped both articles and filed them away, but it kept nagging at me. Well, I had to find out if it's as good as reported and where the feed should be connected.

The basic design of the hentenna is a simple wire loop. It's half a wave high and a sixth of a wave wide, making a tall, skinny-looking quad (total wire loop length is 1-1/3 waves, Fig.1), except it's not fed at the bottom or side, but from the inside. Exactly where on the inside? Near the bottom, but not too near.

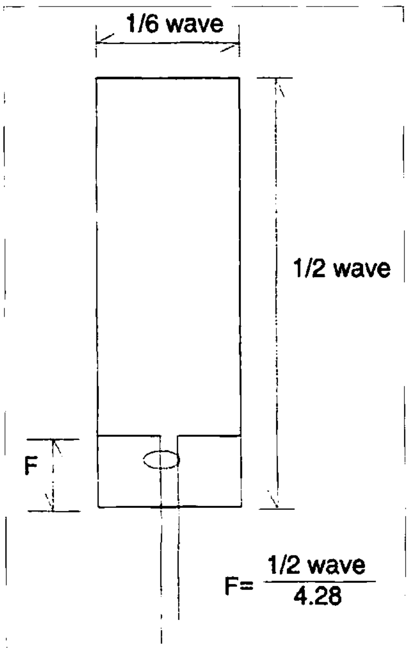

Fig. 1. The basic design of the hentenna is a simple wire loop. It's half a wave high and a sixth of a wave wide.

"Construction is so easy there's no excuse for not having a hentenna around."

Both articles made reference to a skeleton slot antenna to describe how this one works, but to me, it looked like a misshapen quad with a really fat tuning stub. The feed was placed one sixth of a wave up from the bottom, making the top loop, starting from the feed point, one wave long and the bottom loop two-thirds of a wave in length.

To start with I made a UHF model for TV. Using 14-gauge solid copper wire was easy; no supports were needed except the upright, a length of scrap wood (1" x 1"). My choice for a UHF TV station was one of the weaker ones. I didn't want to overpower the antenna and get poor readings. If it pulled in a weak station the lobes should be more pronounced (and they were). This UHF design performed better than I had hoped. Picture quality was equal to a flat four-bay commercial UHF antenna, but the hentenna had narrow lobes (bi-directional). I couldn't twist it much left or right before losing the signal. Tilting it forward or backward also lost the signal. It seemed directional with some gain, but without a boom. Could it work this well on 10 meters? I'd have a winner on my hands if it did.

Constructing the 10 meter hentenna was a little different. All three horizontal members had to be supported to hold up the 14-gauge wire. For the top crossbar I used a 1" x 2" five and a half feet long. For the other two only 1" x 1"s were used.

After soldering the loop together and attaching the top and bottom crosspieces, I measured out 67 1/2" up from the bottom to connect the feed. This starting point turned out to be too high. Measuring with the least possible power output the SWR was 3:1. Lowering the feed point one inch at a time was tedious. I went to three-inch steps, then two-inch steps, and finally one-inch steps. To make it a 1.1:1 SWR, I lowered the feed point 21 inches from where I'd started. I'd been way off. The final SWR curve was so flat I had to check it twice. At 28.0 MHz it had an SWR of 1.2:1, at 29.0 MHz it was 1.5:1, with the trough at 28.4 MHz and a 1:1 SWR, perfect for the Novice band.

Going back to the UHF test model and lowering the feed point to the right spot, I found the performance the same. If the UHF model worked the same, could it be hoped that the 10 meter prototype would be a wire wonder?

Wouldn't you know it? The band was dead. Sure, there are openings even during sunspot lows, but I couldn't find many after building the antenna. I did make some contacts; that says something for this antenna (gotta study those propagation predictions a little more closely). Sorry, not enough on-the-air reports for this one to make any solid conclusions. In general, this antenna is broadbanded with a low SWR. It's directive enough to eliminate some QRM if turned by some means.

LETTERS
Continued from page 6

the newspaper and tell them the date and place of the next ham club meeting. Also, almost every high school has clubs. Find a teacher to sponsor a ham radio club, or get permission to talk to the computer or A/V club at the school. Be willing to spend time with prospective hams, and talk with their parents about the hobby. In recruiting new hams try to shake off the myths of ham radio such as the code obstacle and imagined expense. Point out the high technology of the hobby such as packet radio, SSTV, and circuit building. If just a few hams in every city decided to recruit one new ham in 1996, amateur radio would get the needed hobbyists and you would have a better chance of saving your precious frequencies.

One other suggestion. Public and high school libraries suffer from a dearth of current books on technology, electronics, ham radio, etc. While looking for info on hamming, if I could find books, they'd be twenty to thirty years old. It's hard for me to believe the ARRL wouldn't have some sort of deal where a club could buy certain books for local libraries. *(Ben, when I got interested in amateur radio I first turned to my school library, where I found* QST *and* Radio. *In looking over the 73 subscription records I see very few school libraries subscribing. You or your club could help attract the youngsters we so desperately need by providing gift subscriptions to 73 for your local school and town libraries. Wayne)*

Sacrificing another wire for another band, I grabbed the handie-talkie and headed for the calculator; I'd make a 2 meter version with the ratios from the 10 meter hentenna.

I was sick of converting decimals to English measurements, so metric was the rule of the day (and it was a lot easier). Rewriting the little program to come out in meters was easy; it was just replacing one formula. After doing the calculations and construction in metric it'll be tough to go back to English measurements. I wonder if the local hardware super-store has a 20 meter tape measure? (Ha!)

Construction of the 2 meter hentenna is similar to the UHF model, however, the 2 meter model needed a top crosspiece to support the weight of the wire. Staples held the crosspiece to the upright and the coax to the mast. I don't have a VHF SWR meter, but Hank Koch NFØH does and that weekend he was working on the local repeater. Hank was happy to help out and we charted a few SWR points.

Setting the handie-talkie to 146.000 MHz we read the SWR as 1.3:1. "Hey, you could use it just like that." Hank said. "Let's try down the band." Next at 145.000 MHz it was 1.2:1 and then 1.4:1 at 147.000 MHz. Is that broadbanded enough for you?

I thanked Hank for his help and went home to play twist and chart. The UHF-TV model had such sharp lobes I thought I'd chart the radiation pattern of the 2 meter hentenna. By finding a signal source and then twisting the antenna until the signal strength meter read down three dB (the half power point, Fig. 2) I could chart (roughly) the radiation pattern. The strongest signals were received when the hentenna was held straight up and the face of the antenna held at a 90° angle from the signal source. Tilting the hentenna forward, and then back, gave an estimate of the forward radiation angle. It came out uneven: 35° forward or 40° back brought the signal strength meter to the half power point. Twisting right and left brought more off center readings, 80° one way and 40° the other, the difference being which side the shield is connected to. The largest null is on the side the shield is connected to, 100° from half power point to half power point. On the center conductor side, the null is 20° wide. All this would even out, I guess, with the use of a balun or balanced feed as described in both reference articles (they both used a bazooka feed). I didn't use any matching feed system in my experiments so I could find the 50-ohm feed point without added hardware, and it makes construction easy.

Performance

Performance on the air is surprising. Most radiation is horizontal when held upright, with some vertical polarization, a combination that makes for a good general-purpose antenna. Some gain is evident, as much as a three element yagi maybe. Repeater reception is better when the hentenna is tipped sideways, but not too much.

Tipping the hentenna sideways gave me an idea. If I made a 15 meter hentenna it would fit (tipped horizontally) in the attic. Well, I made it right there in the attic and the SWR was way too high. Thinking that it was the stray capacitance from roofing nails and assorted metal valleys I moved the antenna outside and hung it from the eaves. It hung down to within two feet of the ground and two feet away from the house. Same lousy SWR. What with yard work and winter coming this one would have to wait for another season.

"The hentenna is a great VHF project to add a little gain for portable operations or a simple base antenna for simplex or repeater work as well as the 10 meter Novice band."

The hentenna is a great VHF project to add a little gain for portable operations or a simple base antenna for simplex or repeater work as well as the 10 meter Novice band. Construction is so easy there's no excuse for not having one around.

These are all wire, temporary antennas for experimenting. For outdoor, permanent antennas you'll have to use more durable materials. I had to leave something for you to figure out for yourself, didn't I?

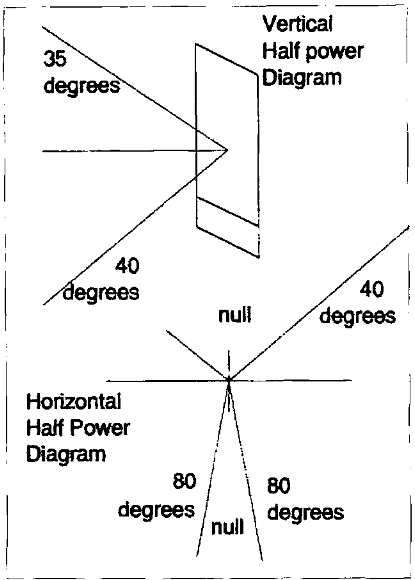

Fig. 2. Hentenna radiation pattern.

Hentenna measurements

Band	1/2 wave	1/6 wave	Feed point
10m	16' 6"	5' 6"	3' 10-1/4"
6m	8' 10"	2' 11-1/4"	2' 1/16 "

The TriField Meter

Do you trust your *microwave oven?*

Michael Jay Geier KB1UM
c/o *73* Magazine
70 Route 202 North
Peterborough NH 03458

This has to be one of the most unusual products I've ever reviewed. The TriField meter is intended to measure magnetic, electric and radio (electromagnetic) fields, in order to help you avoid unnecessary exposure to these controversial emissions. The unit employs separate sensors for magnetic and electric fields, and it comes with a treatise that discusses the probable effects of the various kinds of fields and how the human body responds to them.

The meter itself has three calibrated scales. One reads magnetic fields in the 0 to 100 milligauss range, and also reads electric fields when the unit is set to detect them. The second scale reads much smaller magnetic fields, in the 0 to 3 milligauss range, while the last one reads radio and microwave emissions in the range of 0.1 to 1 milliwatt per square centimeter.

The magnetic and electric field settings are frequency-weighted from 30 to 500 Hz and are calibrated at 60 Hz. The readings increase with frequency. So, a 2-milligauss field at 60 Hz will read "2" on the meter, but a 2-milligauss field at 120 Hz will read "4." This is intentional, because, according to the instructions, the currents induced in the body are proportional to field strength multiplied by frequency. Essentially, that makes the meter an indicator of induced body currents, rather than a field strength measurement device.

The choice of 60 Hz as the reference point was made, of course, because it's our powerline frequency. The unit's sensitivity increases linearly with frequency until about 500 Hz, and then it stays roughly level (± 20%) up to 1 kHz. After that, it gradually reduces to zero at about 100 kHz, although there is some residual sensitivity up to about 100 MHz. Overall accuracy is specified at ± 20% for magnetic fields, and ± 30% for electric fields, RMS at 60 Hz.

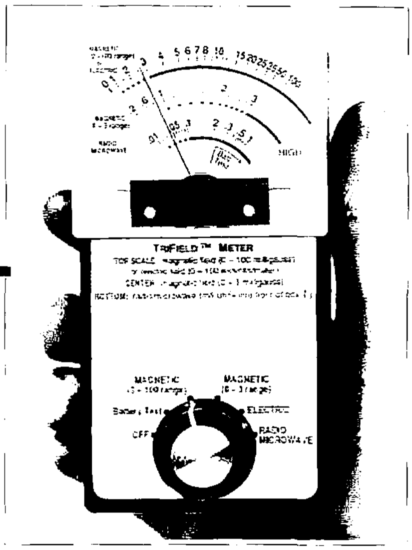
Using it

The meter is housed in a plain plastic box, and is powered by a 9-volt battery, which is supposed to last about 30 hours. Changing the battery requires unscrewing the back of the box.

A rotary knob lets you select the five ranges and a battery test range, which is a handy feature. Although the internal positions of the various sensors are described in the instructions, there's no mention of them on the unit itself. The electric field sensor is at the top of the unit, and the three magnetic sensors are on the front, below the meter. Operation is as simple as selecting the kind of field you want to see and moving the meter around near the field's generator.

The results can be surprising. My laptop shows significant magnetic fields around the hard drive and the power supply for the backlight, as I would expect. It also shows noticeable electric fields in front of the display, no doubt from the backlight element itself. No measurable radio fields are detected, probably because they're at too high a frequency for the TriField meter to have much sensitivity to them.

My desktop computer monitor shows strong magnetic fields near the face of the CRT, but they fade away rapidly. While electromagnetic near fields become



weaker in accordance with the inverse square law (the strength of the field is inversely proportional to the square of the distance), magnetic near fields follow the inverse cube law (they're inversely proportional to the cube of the distance), making them become much weaker for a given distance.

Using the radio setting around the seal of my microwave oven door shows a very low leakage rate; I guess my oven's in good condition. It's reassuring to know I'm not getting cooked along with my dinner!

"It's reassuring to know I'm not getting cooked along with my dinner!"

Is it for you?

This device isn't meant as an antenna field strength meter! Its non-linear interpretation is clearly geared toward telling you what the received fields might be doing to your body, based on induced currents. If you don't know the frequency of the received fields, there's no way to determine whether the actual field strength is, say, 9 milligauss at 60 Hz or 2 milligauss at 250 Hz. So, for normal, home use, the meter is best used as a relative-strength guide to sources of significant emissions, rather than as a method of obtaining actual field strength measurements.

The included paper is well-written and fairly detailed, but it is important to note that no conclusive evidence of harmful effects of low-level fields exists. In fact, the literature goes so far as to state "some readings in the high (red) zone may ultimately prove not to pose a health risk." In

The Big Loopy Skywire

Cheap and simple, with a bodacious signal.

Dean Frazier NH6XK
94-567 Kuaie St.
Miliiani Town HI 96789

When the Loop Skywire is mentioned, most amateurs immediately think of acres of property with no antenna height restrictions. But such conclusions are misconceptions when it comes to putting up a Big Loopy, and generating the "Big Signal." For the Big Loopy, a full-wave loop in the horizontal plane, the area needed, and the best height, are all pretty much dictated by the frequency of the *lowest* amateur band on which operation is desired.

Loop size depends on frequency

For 80 meters, you need 1005/3.75 MHz = 268 feet of wire which would be 268/4 = 67 feet on a side if the antenna is square; but a Big Loopy on 10 meters would require 1005/28.4 MHz = 35.4 feet of wire. That is, 8.85 feet on a square side, and it might as well be hung vertically as a true quad loop. However, there is a point where a vertical loop becomes impractically large to erect: a vertical loop for 40 meters would be 1005/7.15/4 = 35 feet per side, out of the question for most amateurs. But since the radiation from a full-wave loop is not all perpendicular to the plane of the loop, a large loop strung horizontally does work.

My experience, and that of others who have put up a full-wave loop for 80 meters, is that the loop radiation goes up at high angles, which is great for propagation out to about 1,100 miles and multiples of this distance. Upon reflections, the signal comes down "hard." The very first night I tried the Big Loopy, I managed to communicate with the radio operator on an oil tanker in the Caribbean (5,500 miles distant from my QTH in Hawaii) on 80 meters. Although I was running 400 watts I was told that my signal was obnoxiously loud.

The Big Loopy

My Big Loopy measures 285 feet around, and it is not at all round or square, but as seen from above, has the outline of a necktie (see Fig. 1). Although the *Handbooks* recommend 272 feet for the loop on 80–10 meters, I chose this length of wire based on the following calculations:

1005/285 = 3.526 MHz

and multiples of this frequency are

7.053, 10.579, 14.105, 17.632, 21.158, 24.684, and 28.211 MHz

which multiples more or less match my preferred regions of operation on the HF bands. Had a 272-foot length been chosen, all frequencies for lowest SWR given above (for a length of 285 feet) would be shifted higher by a factor of

285/272 = 1.048

e.g., 7.053 MHz would have been 7.39 MHz, *out of band*. Also, the bands for which 285 feet of wire will not quite be on resonance (for which there would be some reactance), are handled by a simple Inductance/Capacitance (L/C) tuner, or "Matchbox," at the shack.

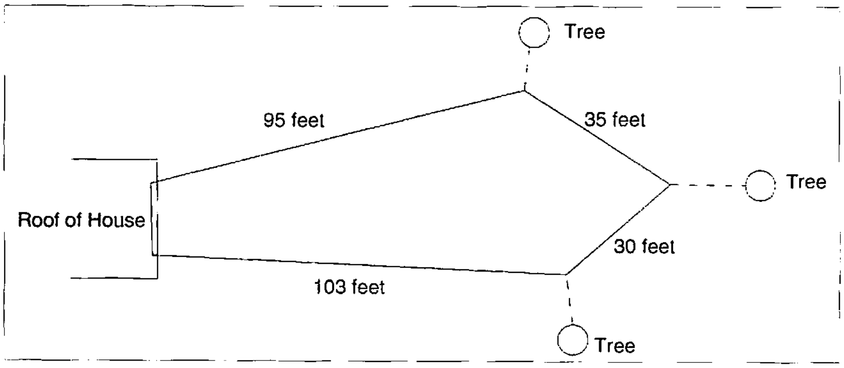

Fig. 1. Layout details of the Big Loopy.

The Big Loopy is fed with 52 ohm coax, as the feed point impedance is between 50 and 100 ohms. Air RF choke baluns are used at both the feed point end and at the shack, to help suppress any RF currents induced on the outer braid of the coax (unbalanced feed line) from the loop radiation. A 1:1 balun at the feed point could be used. And an open ladder-line feed system would probably be best, but up to 700 watts, on all bands through 80 meters, I have not experienced RF.

The feed point is 30 feet up, at the rear end of the house, 70 feet from the shack. The elongated, but not quite folded, dipole outline of the Big Loopy is 40 feet off the ground at its highest point, and the low point is 25 feet high. The long axis orientation is east-west.

As Fig. 1 shows, one end of the wire of the Loopy is connected to the coax center conductor, while the other end returns to the feed point braid. The corners are attached to their respective tie-down points with nylon line. The wire is #12 A.W.G PVC covered solid copper. Note that the east end of Big Loopy is triangular, sloping down, and buried in the forest behind the fence of the property line.

Theoretical considerations suggest that nowhere in the loop should the wire double back on itself; you should try to keep all corners or "turning points" less than or equal to 90° so you don't suffer from signal cancellation. For the strongest signal, you want to make the loop as "open" (covering as much area) as possible. The facts that the loop is neither circular nor square, and is not very high, all result in some increased angle of radiation and reduction in signal strength, but these effects are not as bad as one might guess. The ideal loop would, of course, be circular. With 285 feet taken as the circumference of a circle, this would result in a $285/\pi$ = 90.72 foot diameter circle of 45.35-foot radius, which gives an area of $(45.35)^2 \times \pi$ = 6464 square feet. A square loop in comparison would have sides 285/4 = 71.25 feet, or an area of $(71.25)^2$ = 5077 square feet. The ratio of areas is a measure of radiated signal strength: 5077/6464 = 0.785; dB = 10 log (0.785 = -1 dB. The square loop would be "down" in signal strength from that of a circle's by about 1 dB. As configured, my Big Loopy suffers about 1.5 dB compared to the radiation from a circular loop of the same length wire. However, when you consider that a full-wave loop shows 2 to 3 dB gain over a dipole, at least on 80 meters, I'm still ahead. And on 40 meters, where a full wave 80 meter loop is 2 waves, the Big Loopy has 2x3 = 6 - 1.5 = +4.5 dBd, calculated on the conservative side, or 3x3 = 9 - 1.5 = +7.5 dBd if one is optimistic. Necessarily, doubling the wire, e.g., doubling the number of full waves on the wire at a given frequency, adds about 3 dB of signal strength. On 20 meters, where the Big Loopy is four full waves, then at worst, the gain is 4x3 = 12 - 1.5 = +10.5 dBd. No wonder I am told by hams on the mainland that the Big Loopy produces the "Bodacious Signal."

Furthermore, the Big Loopy is hard to beat when used on 40 and 80 meters, inter-island. I run 10-20 watts, and usually am 59 or "in the red" on the outer islands (Kauai, Maui, Hawaii).

So if you are fortunate enough to have a bit of area, put up a Big Loopy, even if you can only manage 71 feet of wire or so, about 17 to 18 feet on a side, for 20 meters. This will give you 2 waves on 10 meters, and 1-1/2 on 15 meters; the 12 and 17 meter bands being tunable via an ATU or matchbox. Don't worry if your antenna is not exactly square or level or very high. Just put one up and give it a try. You'll put out *some* signal which will go *somewhere*, and you might be pleasantly surprised. And then you can enjoy the fun of tilting a side or an end of Big Loopy to put a lobe where you want. Or you might try loading two sides with about 360 ohms of inductive reactance to create a "Big Baby Loopy" to achieve more gain in a desired direction (see *73 Amateur Radio Today*, November 1992; "Baby Loopy"). 73

The TriField Meter

Continued from page 17

other words, you are free to interpret and worry as you please.

It is important to note that the magnetic field sensors capture only AC fields—you can't use this thing to see how far your speaker magnet's field extends. It is possible to measure steady-state magnetic fields, but it requires a more sophisticated type of measurement device called a magnetometer, which the TriField meter does not contain. As health studies do not currently indict steady-state fields, Alphalab apparently saw no reason to increase the unit's cost to make it possible to measure them.

If you're worried about what your gadgets' fields might be doing to you, the TriField meter will help you find the best placement for your devices and yourself, so that you can minimize your exposure. The price is very reasonable for what it does. It's an interesting and unique product. It's available from Alphalab, Inc., 1280 South Third West, Salt Lake City UT 84101. For additional information contact David at 503-543-6545. 73

Easy to Build 10m Beam

The Sun-spots are coming. The Sun-spots are coming.

Adam J. Felde N6CJU
1627 E. Ave. Q-12
Palmdale CA 93550

This antenna uses four half-wave dipoles whose elements are all cut to the same length. The dipoles are mounted on the boom in piggyback fashion, one above the other. The four dipoles are numbered for identification:

Dipole #1 is at the front of the boom.

Dipole #2 is at the rear.

Dipole #3 is above dipole #1.

Dipole #4 is above dipole #2.

The dipole elements are in a horizontal plane with the earth. This element arrangement allows the use of a quarter-wavelength boom, and makes it possible to use a quarter-wavelength of air space time—the distance between the two sets of dipoles—on an alternate time share basis.

The design frequency is 28.700 MHz. Dipoles #1 and #2 are a set, and dipoles #3 and #4 are a set. Half-inch tubing is used for the dipole elements, which are insulated from each other and the boom. The two sets of dipoles are separated from each other (electrically) by a quarter-wavelength of RG-8U coax delay line. This causes the dipole sets to follow each other by a 90° delay. For example, dipoles #1 and #3 fire in sequence, and dipoles #2 and #4 immediately follow, also in sequence, making one complete cycle of all four dipoles. The close spacing between the elements has no ill effect on performance. Assuming the initiating signal from the transmitter to be a positive-going waveform, dipole #1 will be the first to radiate, followed by #3, whose signal phase has gone negative, along with #2, both of which are 180° for that instant. And, since dipole #3 is at the same place on the boom as dipole #1, dipole #2 will lag dipole #3 by 90° (the distance between dipoles #3 and #2). This will cause a cardioid (heart-shaped) waveform to be radiated from dipoles #1 and #2. In other words, dipoles #1 and #4 radiate a positive-going wave, and dipoles #3 and #2 radiate a negative-going wave. See Fig. 1.

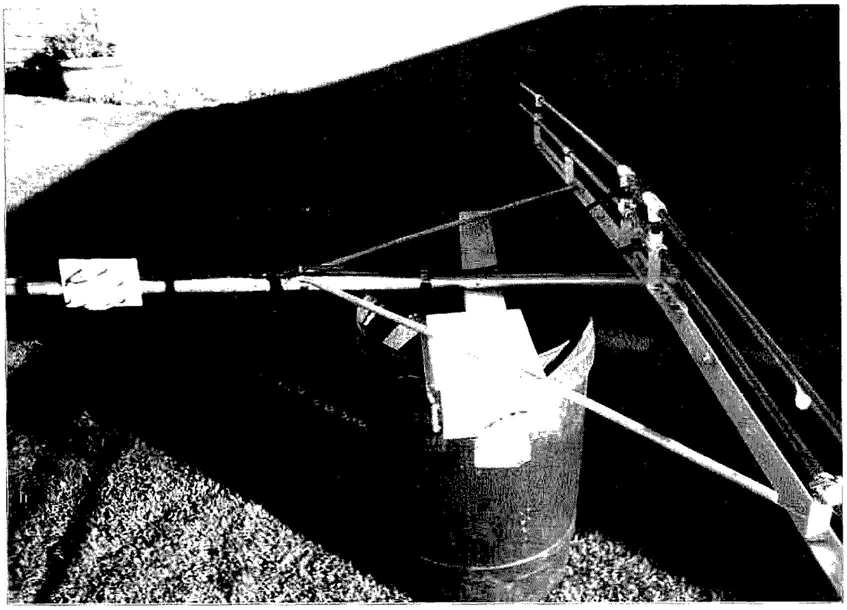

Photo B. *To drill the bolt holes for mounting, flatten 1" of the ends of your 1/2" tubing, creating a support angle stabilizing wishbone.*

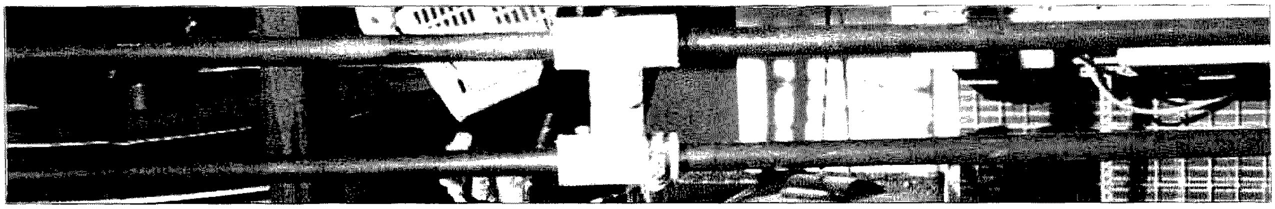

Photo A. *The elements are supported by the PVC plastic three-way "T" of lawn sprinkler pipe to make an "H."*

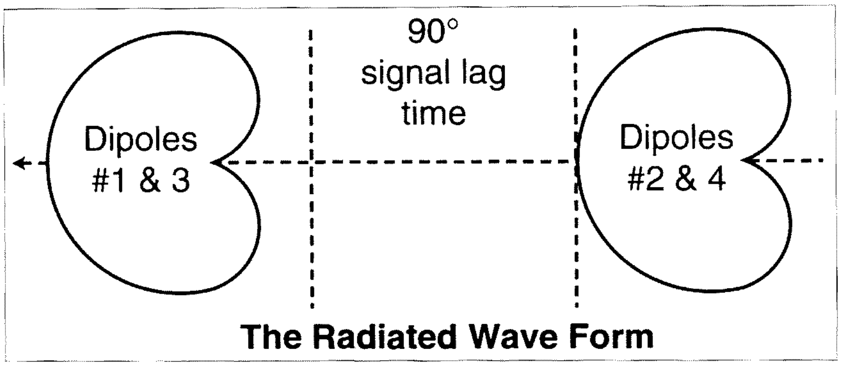

Fig. 1. *The cardioid waveform.*

The SO-239

Drill, in the exact center, a 5/8" hole in a 3/16" thick 3" x 2" piece of Plexiglas™. Drill another hole, capable of receiving a #6 bolt and nut, 1/2" from each end, in the center, to fasten the assembly to the dipole elements. Place an SO-239 chassis adapter/connector plate into the 5/8" hole, and drill four #6 screw holes through the existing holes in the connector body to bolt the SO-239 into the Plexiglas piece. Solder "pigtails" to the connector's center conductor, and to the conductor's outer body, for connection to the dipole elements. Make four of these assemblies, one for each of the dipoles.

Mounting the Dipoles

The dipole elements are mounted on 10-foot aluminum 2" x 2" x 3/16" angles (the elements are insulated from the angles). The boom will be nine feet long. The aluminum dipole support angles will have a "V" stabilizer, reaching from some point on the boom, with the open end of the "V" legs bolted to the aluminum angle spread open to reach at least a two-foot spread on each side of the boom, to make the antenna wiggle-proof (and bird-proof).

The Driven Element

Use a schedule 40 white plastic lawn sprinkler fitting, and a three-way "T" for 1/2" plastic schedule 125. You cut

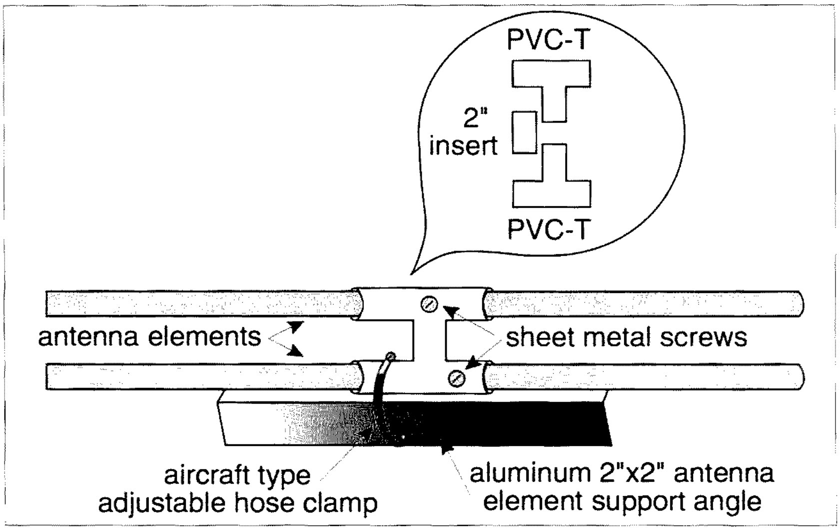

Fig. 2. *A pictorial view of the driven element insulator/supports.*

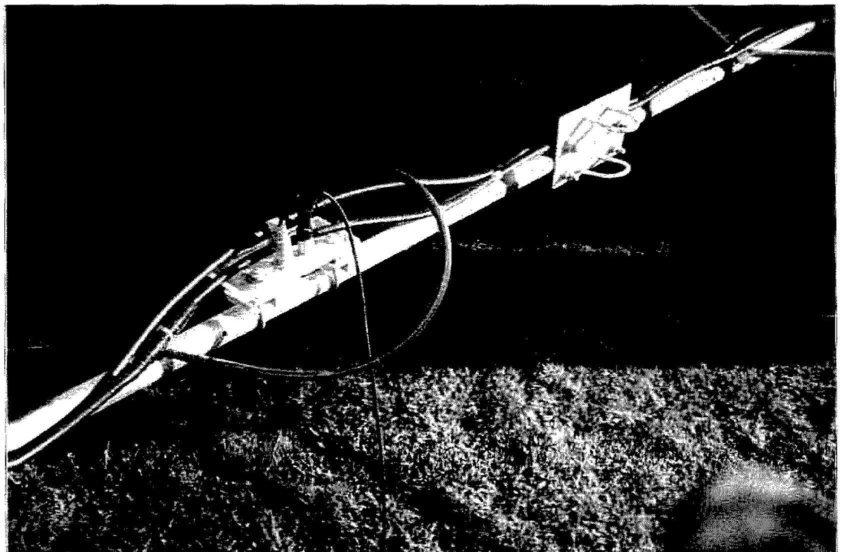

Photo C. *Note the mounting for the delay line and feedline connectors; it's made of 3/16" Plexiglas™ wide enough to receive exhaust pipe-type "U" clamps bolting the unit to the boom.*

a 2" long piece of the schedule 125 pipe to cement into the leg of the "T," then take another "T" and cement the two units together, fashioning an "H." On the boom the "H" will lie sideways. See Fig. 2.

Use an aluminum 2" x 2" x 6' (10-foot is better if you can find it) angle. The insulator/supports you are going to make are clamped to the aluminum angle using #16 adjustable hose clamps. Position the element supports on the aluminum angle so the legs of the "H" are horizontal with the aluminum angle. Clamp them to the aluminum angles shown in Photo D. Slide the dipole elements into the supports and place them so the ends of both halves of the dipole are equidistant from the boom. Drive a sheet metal screw through the plastic support and into the dipole element, being careful not to come in contact with a clamp

and accidentally ground an element. Do this in two places on each dipole element.

The Coax Hookup Assembly

For dipoles #3 and #4, connect one end of a 10' 11" coax into the SO-239 chassis mount on dipole number 4, and connect the other end into the coax "T" (M-358). Connect a 5' 5-1/2" length of coax into the opposite end of the "T," and terminate the coax into the SO-239 chassis mount on dipole #3. Put a PL-258 coupler into the center terminal of the coax "T," and connect another 5' 5-1/2" length of coax to the end of the PL-258 connector. See Fig. 3.

For dipoles #1 and #2, connect one end of the last 10' 11" of coax into the SO-239 chassis mount on dipole #2, and connect the other end into the coax "T" (M-358). Then place a double PL-259 into the coax "T" and connect another coax "T" to it. Then, using a PL-258 connector, connect the center terminal of the second "T" with the

73 Review

CB 148/450 Dual-Band Corner Reflector

Big dual band signals are just around the corner.

Larry Antonuk WB9RRT
Box 452
Marlborough NH 03455

After years and years of doing product reviews, you tend to get fairly immune to boastful claims from various manufacturers. Of course people tend to exaggerate when they're talking about their own products—this is expected, and you learn to filter out the facts from the hyperbole. Still, some products come along described in such glowing terms by their makers that it's hard to keep an open mind when reviewing the product. As an example, I received the product literature for the Arrow Antenna 146/435 Corner Beam antenna well before I got the actual antenna. Glancing over the spec sheets, I found quite a few phrases that got my attention. Consider the Arrow Antenna motto: "Simply the Best." Or maybe the description of the Corner Beam: "This is an impressive antenna, no matter how you look at it." Or even the relatively humble "Arrow Antennas manufactures a very select line of products." Well, I thought, there's no shortage of hubris in Loveland, Colorado.

A few days later, as soon as I slid the antenna out of the package I had a thought: "You know, these guys might be telling the truth!"

What's a corner beam?

Before going into details, it might be a good idea to review the reasoning behind getting a corner reflector in the first place. In the overall scheme of things, corner reflectors have a spot in the logical progression of antenna evolution. The ordinary dipole gave way to the Yagi-Uda, which utilized directors and a reflector. The single reflector was turned into a screen for a greater back-side rejection. The screen was then formed into a right angle (or a 60° or a 45° angle) to improve the front-to-back ratio, which created the corner reflector. If the reflector is rotated in a full circle around the single driven element you get a parabolic dish antenna. Building a parabolic dish at VHF frequencies can be a tricky maneuver. Due to wavelength dimensions, however, a high gain 2 m or 70 cm antenna is most effectively built using corner reflector methods.

So what does a corner reflector have that a plain old Yagi-Uda doesn't? First, it's much shorter. A standard beam antenna with the same 10 dB gain as the Corner Beam would have to be 10 feet long. The Corner Beam's longest element is four feet long, making it ideal for mounting and rotating in a smaller space. Second, the directivity is the same or better than a Yagi-Uda with the same gain. Third, the 40 dB front-to-back ratio makes it ideal for nulling out interference from other stations, or for concentrating all of the signal from a transmitter toward a given geographic area. And fourth, a corner reflector has a much wider bandwidth than a beam. As an example, a typical standard beam will have a 2 to 4 MHz bandwidth with an SWR of less than 2:1. The Corner Beam lets you operate across the entire ham band with an SWR of less than 1.2:1—virtually flat. In addition to all of these benefits, the folks at Arrow Antenna

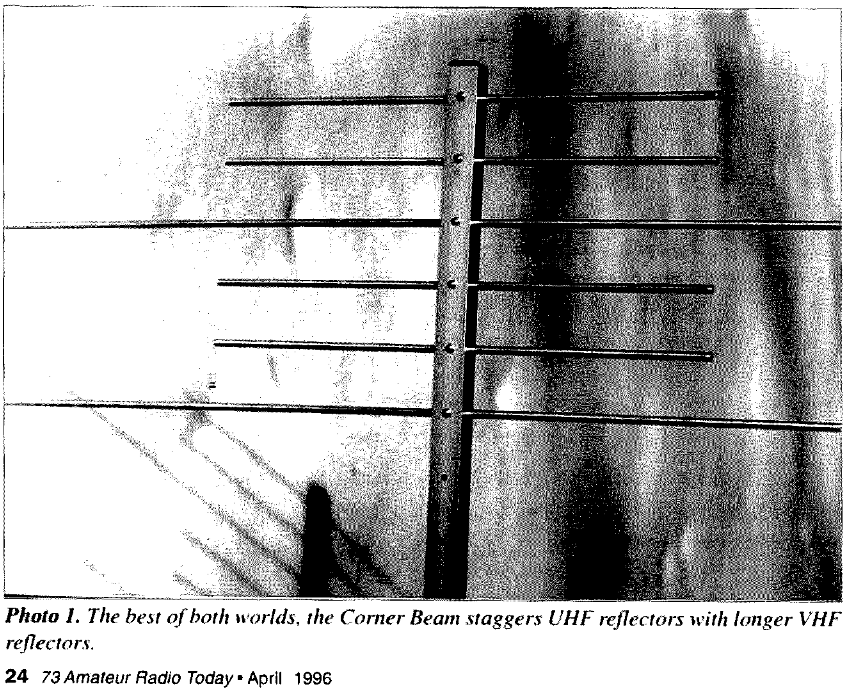

Photo 1. The best of both worlds, the Corner Beam staggers UHF reflectors with longer VHF reflectors.

NEVER SAY DIE

Continued from page 4

Any questions? Okay, now put this down and start doing some serious thinking.

If you don't know how to find out about health, then for heaven's sakes at least send $5 for my list of books "you're crazy if you don't read." There are a bunch of the more important health books on the list. And if you want to find out how to start your own business then you could do worse than invest $5 in my booklet on "Making Money," which I wrote after getting a bunch of requests for it from the Art Bell radio talk show listeners.

One of these days I'll have all that stuff on a web page for you, but until then I can't reprint things I've

Continued on page 35

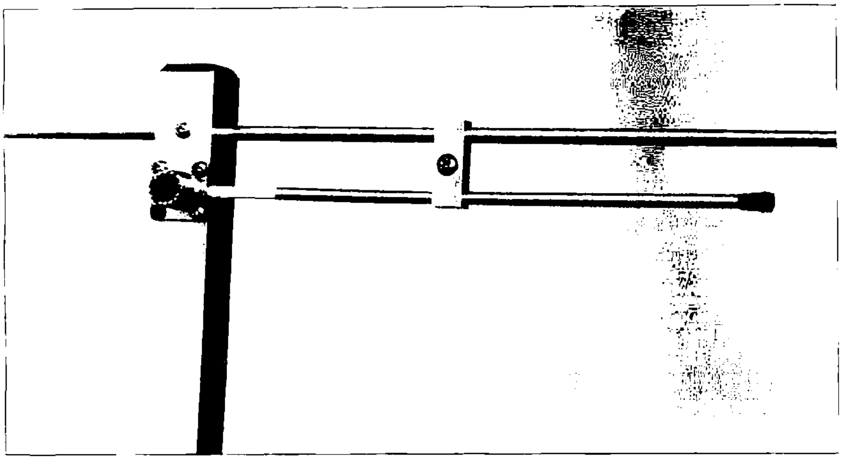

Photo 2. Quality construction is evident in this closeup of the VHF driven element and gamma match.

have created a dual-band version of the corner reflector. The 146/435 consists of two separate corner reflectors sharing the same boom structure. The shorter UHF elements are interspersed with the longer VHF elements, and both driven elements share the center boom. Because of the vast difference in frequency the elements for each band are "invisible" to the elements in the other frequency band, meaning that you can have two high gain, highly directional antennas in the space needed for one VHF corner reflector. You can use them both at the same time if you have separate radios, or use them with a duplexer and a single run of coax with your dual band transceiver.

An impressive antenna?

Once you've decided that a corner reflector is just the thing for your repeater or packet link, is the Arrow Corner Beam the way to go? Is it really "an impressive antenna, no matter how you look at it."? Yes. The quality that goes into the Arrow Antenna products is obvious, from the second you open the package. It comes completely broken down in a 4" x 4" x 4' box. Each of the booms is wrapped in plastic to avoid scratches during shipping, and these are wrapped together with foam packing. Hardware is carefully packaged, and the elements are stored in the boom tubing. The three booms are made of 1" square T-6061 aluminum tubing, a high grade material used in many industrial applications. The reflectors and driven elements are made from quarter-inch solid aluminum rod—not tubing. The gamma match on the driven element consists of a carefully machined shorting bar, along with a plastic insulator for the rod that comes up from the SO-239 (VHF) or N (UHF) connector. Even the design of the gamma match is well thought out—the shorting bar and match are aligned in the plane of the main boom, meaning that the pattern of the antenna will be truly symmetrical. The hardware is all stainless. The documentation is not extensive, but very clear.

Anyone should be able to assemble this antenna in under an hour, using just a Phillips-head screwdriver and a couple of adjustable wrenches. As I assembled the antenna, the quality of the product became more and more evident. All the holes were precisely drilled and completely deburred—all the reflectors slid smoothly through the booms, and all the mounting screws then threaded easily into each reflector. There was no missing hardware, and the gamma matches went together and tuned up easily.

The main boom allows for easy mounting to a tower leg or mast section, in either a vertical or horizontal orientation. (Of course, you can't split the polarity between bands—both driven elements are on the same boom, and both will always be the same polarity.)

But does it work?

Regardless of how well made an antenna is, the proof of the product is in the operating. I already had a three element dual-band Yagi mounted on my rotatable mast. I mounted the 146/435 right below this antenna and borrowed one coax run from the Yagi, running both antennas on 450 MHz. This allowed me to use the switch box to run A/B comparisons. Obviously, the comparison was not totally fair—the Corner Beam has quite a forward gain advantage over the Yagi. Still, the results showed how big a difference a few dB can make. Signals that were barely readable on the Yagi came in loud and clear on the Corner Beam. Signals that were just barely workable on the Corner Beam were simply not to be found using the Yagi.

What can I do with it?

What are some of the applications for an antenna of this type? The fact that the 146/435 is actually two antennas in one, and no more than four feet on its longest side, means that it's a very space-efficient antenna that still gives you the gain of the big beams. If you have a small amount of antenna space the Corner Beam might be just the ticket—mounted on a rotating mast, on a tower leg, to the side of your house, or even tucked in the attic. The great front-to-back ratio of this antenna makes it useful for a lot more than simple home station applications, however. You might have a repeater that needs to cover a fixed area. Perhaps the only hill in your area is way north of town, and you have no interest in covering anything to the north of the hill. Why not concentrate all your power back toward town, instead of spreading signal where it isn't needed? Most repeater groups probably have another repeater on your frequency in the next state that gives you trouble now and again. Why not use the Corner Beam (or two) to null out the interference from the other site? More esoteric applications abound. Corner Beams would make excellent antennas for use with passive repeaters—two back-to-back antennas, used to dribble some signal into areas otherwise unreachable by the main repeater. Any fixed data or packet application would be well served by a corner reflector. How about a VHF/UHF crossband repeater, using only one antenna? Foxhunters will have fun with this

antenna as well. Put the fox in a hard to reach spot, and point the Corner Beam at an easy to reach hill. With very little signal coming off the back of the beam, and lots of signal coming off the hill, all but the craftiest hunters will be kept busy for hours.

Drawbacks

Actually, I could find nothing negative with this antenna. However, one point to consider before you purchase any corner reflector concerns the wind load of the antenna. The wind load of the 146/435 is specified at less than three square feet, which puts it in a league with a 20 element 2 m beam. This in itself is not a problem, but bear in mind that the wind load (and the weight of the antenna) is asymmetrical—all of the wind and weight load hangs off one side of the mast, greatly increasing the amount of torque that can be applied to the mast and rotator. This means that while you can probably get by with an inexpensive TV rotor to turn this antenna, you might run into problems during high winds or icing conditions. The best approach would be to use a heavy duty rotator, or to mount the Corner Beam on your main mast under your HF beam.

Is it "simply the best?"

Is it the best in the whole world? No. If you have a bottomless checkbook you can find some commercial antennas that are even more rugged than the Arrow Corner Beam—at about ten times the price ($165). Is it the best in the amateur market? I think it is. Is it the best bet for gain and quality per unit price? Absolutely. Regardless of your application, you'll be hard pressed to find a better way to spend your antenna dollars. The Arrow Corner Beam uses construction techniques that rival or exceed many commercial antennas, at an affordable amateur price. It's a pleasure to see that a company has taken a stand with quality materials and excellent craftsmanship, and that stands behind its products with a ninety 90 day, no hassle refund policy. In addition to the 146/435 dual band antenna, the Corner Beam is also available in single band versions in 148, 220, and 450 MHz models. Any of these antennas may be obtained through Arrow Antennas and are nationally distributed through Antennas West, Box 50062, Provo UT 84605 (800) 926-7373.

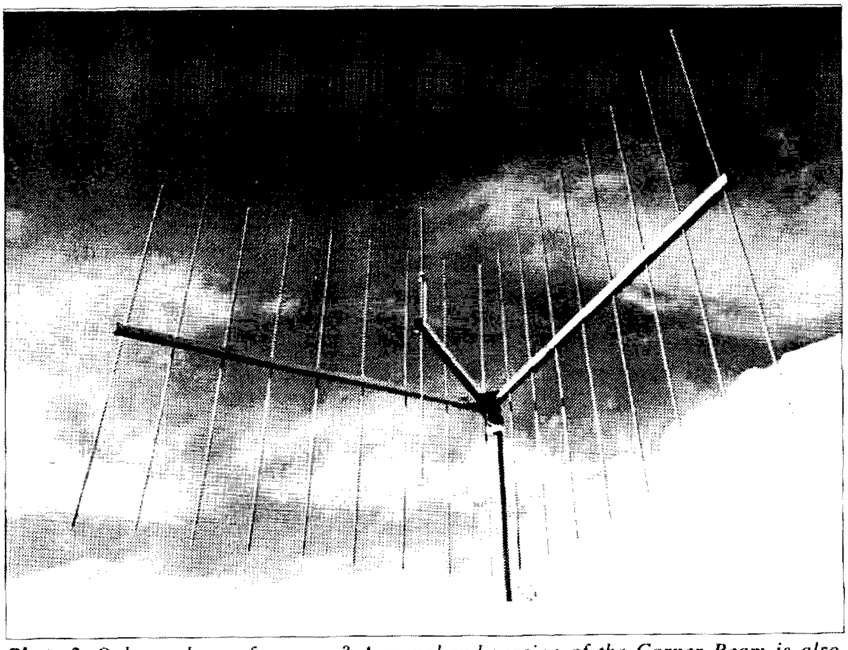

Photo 3. Only work one frequency? A monoband version of the Corner Beam is also available from Arrow.

73 Magazine is looking for talented personnel. If you are literate in English, computers (Mac best and/or others is great), and/or are a ham with technical skills...call Frances. If you have desktop publishing (Pagemaker and/or Quark), marketing, telephone sales, and/or circulation management skills...call Frances. 603 924 0058

Johnson Matchbox Renaissance

A flea market winner! Or, build one yourself.

John Sehring WB2EQG
P.O. Box 373
Baker MT 59313

A recent article in *QST* which evaluated a number of different antenna-matching devices caught my attention. The venerable Johnson Matchbox got high marks for efficiency and degree of balance. It was proven to compensate for a fair amount of reactance from an antenna operated off-resonance.

"The Real McCoy" may be hard to find but dedicated hams can build accurate working copies."

I had always wanted a Matchbox in order to feed my large balanced-fed loop antenna with 50 ohm coax on all bands, but I'd never found a Matchbox at ham radio flea markets for the right price. I built a copy of one instead. It was an uncertain affair because I had only a small photo of the innards of a Matchbox to guide me. Matchboxes are somewhat hard to find (they haven't been made for about 35 years) so I think that others might want to build accurate copies. Mine is the version of the Matchbox that is conservatively rated at 275 watts (a kilowatt-rated model was also manufactured).

Main Coil

The construction of the main coil (L1) is unusual: the two ends of the coil are wound with a smaller turn spacing than the middle section. The coil is symmetrical in construction as it is intended to be connected to a balanced line. The pitch of the two end sections is 8.5 turns per inch. This is equal to a center-to-center wire spacing, between adjacent turns, of about 0.12 inch. Each end of the coil contains 14.75 turns.

The pitch of the center section changes to 4.3 turns per inch in about one-quarter turn (90°) of the coil. This gives a center-to-center wire spacing between adjacent turns of about 0.23 inch. The center portion contains 5 turns.

The length of the entire coil (two end sections plus center section) is 4.5 inches; its outside diameter is 2.7 inches. The entire coil is air wound on

Ham Radio and Summer School

The 1995 session at Sno-Isle.

Larry R. Luchi W7KZE
P.O. Box 1612
Mukilteo WA 98275

I was hooked after being introduced to amateur radio in the sixth grade, and have been licensed for more than 40 years: the 1980s brought a career change, and now, as an Electronics Technology instructor at Sno-Isle Skills Center in Everett, Washington, I spend my time teaching my hobby.

The Skills Center, serving 25 area high schools, is the largest of nine Skills Centers in the state, with 22 vocational training programs for approximately 850 students. The school's name comes from the combination of Snohomish and Island counties. From the school one can see the Olympic Mountains to the west and the majestic North Cascades to the east, just 25 miles north of Seattle.

Some students take the ferry from Island county and others are bused from the 13 school districts served by Sno-Isle, for two three-hour blocks of daily instruction (a morning class and an afternoon class). These students receive three elective credits per school year for their training. In the third quarter of this two-year program, I teach amateur radio (communications electronics). All of my students have Novice, Technician Plus, or higher-level licenses by the time they graduate from high school.

Photo A. Sarah, Larry W7KZE, Allan Falkner, talking with Frank W8OK on 20m. Visoth Sieu looking on.

For the past 10 years I have also taught a summer school course in ham radio. My summer school course not only helps kids to get their amateur radio licenses, but also introduces them to electronics in a hands-on training environment.

"My summer school course not only helps kids to get their amateur radio licenses, but also introduces them to electronics in a hands-on training environment."

Summer school is fun. The superintendent of public instruction allocates funds each year for a 90-hour, one-half credit course of instruction for students from the ninth through the twelfth grades. The only costs to the students are bus fare and lunch.

About five years ago, while teaching summer school, I had the pleasure of meeting the Guru of the Dayton Amateur Radio Association, Frank Schwab W8OK. Frank was visiting his daughter, Pat Anderson, and family in nearby Lake Stevens. (Pat is one of 12 children; I asked Frank how he had time to help create the Dayton Hamvention in 1958 with all those kids!)

This year's projects

Summer school this year had 19 students. As usual, I asked all my students to tell the class about themselves and why they are attending summer school. To my surprise the first student was Sarah Anderson, Frank W8OK's granddaughter. The second student to speak up was Allen Falkner; his parents, James and Phoebe Falkner, WA7VQO and KA7WPG, wanted him to become part of a "ham family." After the introductions, I explained the course of instruction and issued each student a copy of *Luchi's No-Code Technician Class License Guide*. Soldering was the first skill that each student was to master; then we moved on to the code.

I used *Super Morse* on my PC. To the kids it was almost the same as a video game. Ninth-graders Sarah Anderson and Dustin Hebner mastered this approach to learning the code quickly. They both passed the 5 wpm exam at our volunteer examiners' session.

To add to the fun, I gave the kids two kits to build and take home at the end of school. One was a code practice oscillator kit. John Fluke Manufacturing Company donates these kits each year to my program, complete with a printed circuit board. The second project was an AM-FM receiver kit that the students built. This provided a break between code practice, rules, regulations and electronics theory lectures, and gave the students some hands-on training.

I also organized the kids into work teams. One team replaced N-connectors on our AOP Oscar antenna array while another team relocated our AEA IsoPole 2 meter antenna and replaced the PL-259 coaxial connectors. All the students rotated jobs to receive as much exposure as possible to the different aspects of ham radio.

Back to the ham shack for a schedule with Sarah's grandfather, Frank W8OK, on 20 meters. Now it was time for on-the-air practice. Sarah eagerly waited to talk to her grandfather. W8OK came through with a 59 signal. He gave us a 57 for my Kenwood TS-50 to a four-band three element beam. Sarah was the

first to exchange greetings with Frank, followed by the other students. Only one student was a little mike shy.

On the final day of summer school, certificates of completion were passed out as our volunteer examiners prepared the test. Sarah, Dustin and Matt Watson passed their 5 wpm test. Seven students passed the code and Elements 2 and 3A for their Technician-Plus licenses, and three passed Elements 2 and 3A for their no-code Technician licenses. Summer school 1995 thus was a very rewarding experience for me and my students.

After all exams were graded we held our final schedule with W8OK on 14,270-kHz. Frank came through with a strong signal and one question. "How did the test go?" I handed the mike to Sarah and she told her grandpa the good news. Then all of the students made their first QSO with W8OK. Frank talked to our Elmers and thanked them for all of their help.

Our summer school ham radio program was successful, with help from the electronics industry and Elmers from the community. Del Talf W7EVI, who was first licensed in 1935, and Dave Johnson NJ7Z and Jeff Fasulo N1HBQ, both from Boeing, completed our VE team. These Elmers gave the kids the help and encouragement they needed to become good amateur radio operators.

Photos by Bob Higbee, Sno-Isle Skills Center counselor.

Publisher's Note:

Permission is granted to copy this article for use in influencing school boards and administrators on the value of adding a course in modern communications technology to their curriculum, summer and winter.

Since we're well into the electronic age, this is a terrible time to keep our kids ignorant of the fundamentals of electronics and radio. These are the days of digital compact discs, of digital television, digital cameras, digital broadcast radio, direct satellite broadcasting, paging services, cellular phones, security systems, global fax, and the world wide web. Amateur radio provides an exciting and fun way of learning the basics of these technologies, with our network of thousands of repeaters covering the country (and in over a hundred other countries), with our digital packet networks, our bulletin board services (BBS), and our two-dozen-plus ham satellites.

Amateur radio and computer technology have come together with weather satellite pictures, slow scan TV, packet, radio-teletype, and high speed Morse Code contacts.

Electronics runs our typewriters, our manufacturing machines, our cars, our watches, our offices, and even our kitchens. Medical electronics is a huge business today. Thus, the earlier kids can learn to understand the fundamentals of electricity and electronics, the better opportunity they're going to have to cope with the information age. And what better way to learn than by having fun every inch of the way via amateur radio?

A knowledge of electronics provides a tremendous boost in self esteem for kids. They learn hands-on by building kits. They build confidence in communicating with people by talking with hams in almost 400 different countries. They learn about geography. Most people may not have a clue as to where Lesotho is, but hams even know the radio prefix (7P8). Look up 7P8CA and you'll find that's me! Because of my interest in amateur radio I've operated from Swaziland, Sarawak, Sabah, Sweden, Spain, South Korea, Syria, Switzerland, Sudan, Sri Lanka, South Africa, Singapore, Scotland, St. Pierre, St. Lucia, and other wonderful places around the world. I was FO8AS on Tahiti, VR2FD on Fiji, 5W4AS on Western Samoa, JY8AA in Jordan, and so on.

Speaking of Jordan, the reason that country is the foremost in technology in the Arab world is because the king (JY1) has set up amateur radio stations and clubs in almost every school in the country. How has Japan beat us so thoroughly in so many electronic industries? Every school in Japan has an amateur radio club. There are over twice as many Japanese radio amateurs as Americans, with half our population. When I visit the Japanese electronic research laboratories, I'm greeted by radio amateurs at every turn.

Every American youngster should be taught about electricity, and what better way than via a hobby which provides a lifetime of fun, learning and adventure? It can also be one of the more inexpensive hobbies, with kits and used equipment keeping the cost low. There are hundreds of "hamfests" all around the country where hams get together to swap equipment and parts.

Youngsters of four have gotten their Novice licenses, and girls of seven have attained the Extra Class license, the highest class available, so the hobby is open to kids of all ages. The only thing lacking is the opportunity for kids to get together with older hams as teachers. That's up to local schools to organize. They will find no shortage of local ham volunteers to mentor the kids. We call it "elmering."

Alaskan Amateurs and Their Antennas

Amateur radio way up North.

George Pataki WB2AQC
84-87 Kendrick Place
Jamaica NY 11432

In the summer of 1994 I toured Alaska. In 29 days I visited more than 90 hams in 15 different localities, and I took more than 640 photographs. I wanted to see how they cope with the weather and the unusual propagation prevailing on the top of the world. (Somebody suggested studying the correlation between the long winter nights and population growth, but I decided that is none of my business. I don't care what they do in the privacy of their igloos, as long they answer my QSL cards.)

Some facts of life up north were as I expected; others were revelations. I knew, for example, that the Aurora Borealis, or Northern Lights, can wipe out radio communications even during the best propagation periods, but the thing that most surprised me was the very warm weather I encountered in the Fairbanks vicinity, at about 100 miles south of the Arctic Circle. I also found out that the seemingly endless rain in Southeastern Alaska can be very depressing, but I will focus here on a single subject: the antennas used by Alaskan hams.

Photo A. Bill KL7ITI in Anchorage.

"Radio communications is not just a hobby; it is an everyday necessity."

First, as can be expected, the antennas, towers, rotators and cables have to be ordered from suppliers in the "Lower 48" states, or occasionally from Canada. Everything has to be shipped long distances and costs go up. Then, because of strong winds, the antennas have to be well built and the towers have to be secured with strong guy wires. I didn't see one single quad antenna, which is an excellent performer, but doesn't resist high winds well. I noticed many wire dipoles, especially for the 40, 80, and 160 meter bands.

Has anybody seen my yagi?

The vast majority of the antennas for the 10 to 40 meter bands I saw were three- to six-element yagis. Most of the antennas were installed on tall, well anchored towers, a few on steel pipes. In Anchorage I saw three-element yagi type antennas of Bill KL7ITI; Harvey NL7DK; Rick KL7YF and his wife NL7DL; Chuck KL7PJ and his wife Marge KL7YG. Simon NL7VR and his family of hams are using a five-element tribander. John KL7GNP runs the Alaskan QSL bureau, and uses a six-element beam. Harley KL7IZZ and his spouse Arlene KL7HO share a huge six- element tribander.

On the roof of the five-story Pioneers' Home, a retirement and nursing home in Anchorage, is a three element tribander connected both to the club station and to the private station of Allen KL7GU. Jim KL7CC has not one but two towers in his backyard; each supports various yagis with three, five and seven elements, and some wire antennas.

The most fascinating antenna I saw in Anchorage was built by Mike KL7X. It consists of four groups of four yagis, each with six elements, and is used for Earth-Moon-Earth communications. Mike worked 30 DX countries and almost finished his Worked All States on EME.

In Palmer, Nate KL7DJE installed his six-element tribander, as well as a couple of other antennas, on a tower that seems to be about 70 feet tall. In the back yard of Bob NL7ZG, the president of the Mat-Su amateur radio club, besides a four-element beam, I saw a complex antenna, possible for EME communications. Unfortunately, Bob was not at home, so I couldn't learn anything about his antennas.

In nearby Eagle River, Hannelore NL7EA and her husband Mark KL7TQ use a six-element yagi.

Also using a six-element beam are Bob KL7AM and his wife Luisa WL7BNX in Fairbanks. In the same city, Chuck K7JUT/KL7 has a four-element tribander, mounted on a self-supporting 70-foot tower.

In the town of North Pole, up the road from Fairbanks, Eric KL7AJ and his 16-year-old son David WL7NK operate with a three-element beam installed on the top of a 30-foot steel pipe. Not far away is Joel WL7AI; he has a three-

element yagi and his repeater antenna on a very tall and well-anchored tower. Also residing in North Pole is the ham family of Ed KL7XD, his wife Sandy WL7PQ, daughter Danielle WL7QW, and two sons, Bill KL7TC and Mike KL7YY. They have two large towers, each with a couple of yagis.

The most fantastic setup I ever saw belongs to Rich KL7RA, on a 20-acre estate in Chena Hot Springs. His contest station has seven towers, some of them over 200 feet tall, each with beam antennas for a different band.

The club station of the US Coast Guard Station in Kodiak, KL7HKX, has two towers; one with a seven-element yagi, the other with two antennas: a four- and a three-element beam. Both antennas are connected to the station with underground cables. Mike KL7JBV, Chief of the Kodiak Fire Department, has a tower and a five-element tribander. Chuck WL7EM easily climbs up his anchored tower, about 60 feet high, to reach his three-element tribander. Also in Kodiak, Henry KL7ALJ has a six-element yagi on top of a 70-foot solidly-anchored wooden pole.

In Juneau, the state capital, Rick N6IV/KL7 shares a three-element tribander with Herb WL7BIL and his spouse Cynthia KL7IZE.

In Auke Bay, George W3ML/KL7 has a four-element tribander on top of a tower erected on the shores of Auke Lake.

In Sitka, Sal KL7BJC has a four-element beam; Leo NL7XW is using a three-element tribander; and Bill AL7KX has a four-element yagi and a couple of other antennas on the same tower.

In Petersburg, Ed KL7DYS and his wife Mildred WL7ALG share their six-element tribander. Their house, with the tower and beam, is only a couple of yards from the water of the Inside Passage, which should make radio communications easy.

In Ketchikan, Chris KL7GIH has a six-element beam for 6 meters, his favorite band, and a wire antenna for 160 meters. Hank KL7IBG uses a five-element tribander.

A seldom-seen antenna is the one designed for satellite communications. Simon NL7VR has one in his back yard and is using it for Oscar-13. A similar setup is the antenna system operated by Jim KL7CC. Both of these hams live in Anchorage, the largest city in Alaska, where most of the active amateurs reside.

Rubber Duckie, you're the one!

In Alaska, recreational vehicles and boats are everywhere, and every one is equipped with some sort of radio. Buildings bristle with vertical antennas, most of them used by CBers, and in the coastal towns, for marine radios. Radio communications is not just a hobby; it is an everyday necessity.

The most commonly used antennas in Alaska are the little rubber duckies. Technician licensees cannot yack on the lower bands, and nowadays 10 meters is rarely usable, so they limit themselves to HTs and operate on 2 meters and 70 cm. Even the higher category ham operators have, besides the big station at home and small ones in their car, truck, boat or plane, one or more HTs. In some instances, when there are several hams in a family, everyone uses them.

In Kodiak at the US Coast Guard station I met Dean WL7RK, a helicopter pilot, his wife Alesia WL7RL, and their son Brian WL7RJ. All three have their own HTs and dune buggies; they travel convoy style, and they are in constant radio contact even when they are only a few feet apart.

Joe WL7AML, in Kodiak, can use his HT with the rubber duckie to talk with hams in Homer, 140 miles away. The trick is that he has to climb on Pillar Mountain and place his radio in the proper position in front of a 60- by 60-foot dish abandoned by the military. A little duckie can do wonders in the right setting.

Matt WL7LX, in Petersburg, may leave home without his American Express card, but never without his HT. It's used on his little boat when he's going fishing, in the bush when he's hunting, and it's small enough to run with if he spots a bear.

The USCG Cutter *Sherman* I saw in Juneau is equipped with all kinds of antennas and sophisticated communications gear. However, crew member Slade KC4WVL uses his little HT with a modest rubber duckie to contact other hams wherever the ship takes him.

Other frequently seen amateur radio antennas are the 2 meter and the dual-band mobile antennas installed on cars, pickups, motorhomes, and boats. Dave KL7M is a taxi driver in Anchorage and makes QSOs while working. Joe NL7RX, in the same city, works on a tow truck; I had a contact with him while he was picking up a wrecked car.

Photo B. Chuck K7JUT/KL7 in Fairbanks.

Verticals for amateur radio? I saw just a few. In Kodiak one is used by Curt AL7LQ; in Juneau by Don WL7ME, and by his neighbor Curtis WL7PX; in Homer by Clarence WØURD/KL7; in Palmer by Jack AL7HN; in Sitka by Hal KL7BCS; in Petersburg by Ed WL7CFZ; in Wrangell by Bob KL7JCZ and by Doug WL7LR.

Solid radio contacts, besides needing good operational skills, favorable

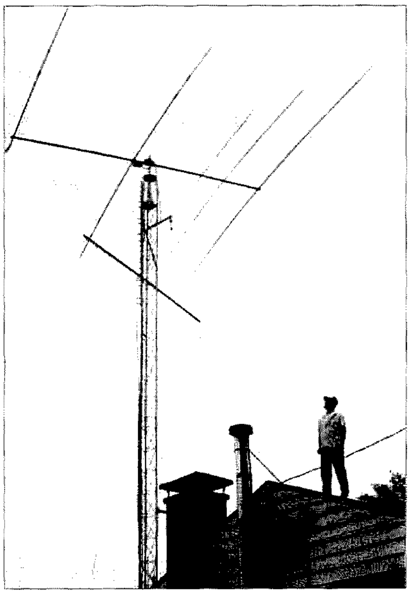

Photo C. Bill AL7KX in Sitka.

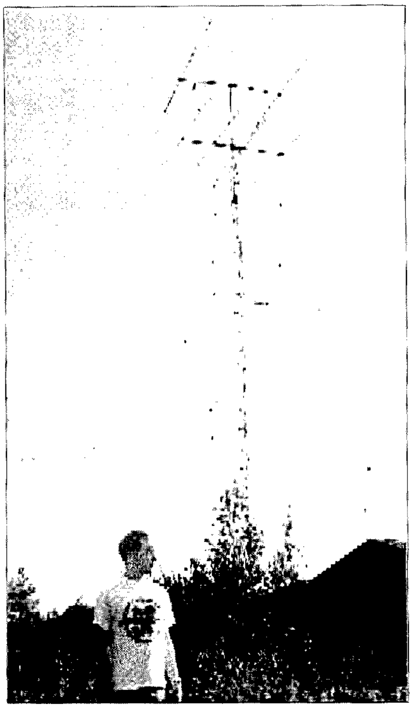

Photo D. Bill KL7TC in North Pole.

location and propagation, also require reliable equipment: antennas, receivers and transmitters. Of all the investments an amateur radio operator can make, the choice of antenna is the most important, and Alaskan hams know it well. Remember, however, the old saying: If your antenna didn't fall last winter, it wasn't high enough.

The photographs show some of the antennas I saw in Alaska, but keep in mind that these little photos cannot begin to show the real scope of a 100- or 200-foot tower with a couple of huge five- or seven-element yagis on the top!

Easy to Build 10m

Continued from page 23

coax from dipole assemblies #3 and #4. Connect the last 5' 5-1/2" coax into the coax "T" and terminate the coax into the SO-239 chassis mount on dipole #1. Complete the assembly by connecting transmission feedline into the center terminal of the coax "T" using a PL-258 coupler.

Parts List

- 24 PVC Schedule 40 1/2" "T" plastic lawn sprinkler fittings
- 24 PVC Schedule 40 1/2" 1-inch long plastic pipe sections
- 12 3" adjustable stainless steel hose clamps
- 4 1 x 1 6' aluminum angle (for the element support)
- 4 1/2" x 10' aluminum tubing for the elements
- 4 3"X2" 3/16" thick Plexiglas™
- 2 "U" bolt type clamps
- 4 SO-239 chassis mounts for RG-8U coax
- 3 M-358 "T" coax adapters
- 1 M-359 right angle adapter
- 1 PL-258 coupler
- 16 Phillips 3/4 inch long sheet metal screws
- 1 Small can of PVC cement
- 3 Lengths of RG-8U, each 1/4 wave long, PL-259 connector at each end
- 2 Lengths of RG-8U, each 1/2 wave long, PL-259 connector at each end
- 1 Suitable 10-foot boom

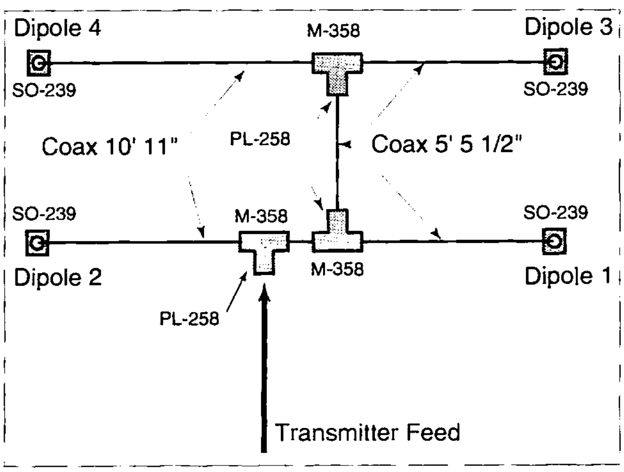

Fig. 3. The coax road map.

Never Say Die

Continued from page 25

published in past issues of *73* just because you don't keep my thousand-plus old editorials on file and cross indexed. Most of the stuff in my booklets originally appeared in my editorials at one time or another.

Can I get you to think things over and decide to make some major changes in your life? A diet change for you and your family will eliminate the problem of degenerative illnesses. It means eating different food and water, and adding the vitamins and minerals that have long been gone from our soil. It means daily exercise. Maybe a job change to something more fun. Some ham radio challenges...like perhaps getting on the ham satellites. How about finding a better school for your kids? Most public schools suck.

Are there some skills you'd like to build? Books you'd like to read? TV you can do without? In the long run will you be better off for having watched a rented old movie or in reading a book? Or is what you're doing today so much more important to you than your quality of life ten, twenty or 50 years from now?

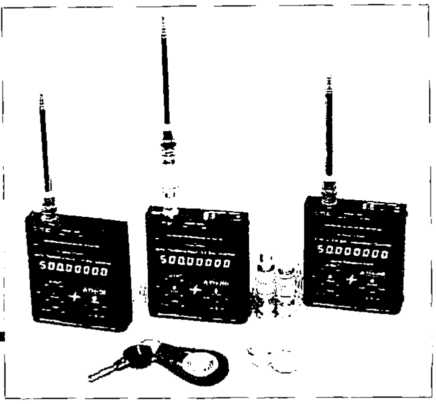
73 Review

Startek ATH-50 Frequency Counter



Functions, features, and fun!

Larry R. Antonuk WB9RRT
P.O. Box 452
Marlborough NH 03458

Now that the prices of some handheld frequency counters are dropping to the $100 range, more and more hams are finding themselves in the market for one. Let's look at the ATH-50 Counter from International. This top-of-the-line unit has all the functions and features you could want in a piece of handheld equipment. By reviewing each of these functions you'll be able to decide which ones are more important for your application, and you'll be able to make a more informed decision when you make your frequency counter purchase.

The basics

At the basic level, frequency counters do just what you'd expect—they count frequencies. The first question you need to ask is, "What frequencies do I need to count?" As a general rule, the higher the frequency you need to count, the more deluxe the frequency counter needed, and the higher the price. The ATH-50 will count frequencies up to 2.8 GHz, making it useful for work on the 23 cm band, as well as on 2.3 and 2.39 GHz.

If you don't venture beyond 2 meters you might be totally happy with one of the other units in the line that have a high limit of 1200 or 1500 MHz. However, one point that is frequently overlooked is the low side of the frequency range. While most of the line starts counting at 1 MHz, the ATH-50 has a low range limit of 5 Hz! This means that in addition to being a full-featured RF frequency counter, this unit can perform audio functions, making it ideal for checking and adjusting CTCSS encoders, DTMF encoders and decoders, checking packet modem tones—anything down to a resolution of 1 Hz. This low frequency mode is only available on the ATH-50, but it might be well worth the money in your particular application, even if you're sure you're never going to venture beyond 2 meters.

The next specification to check out is the unit's sensitivity. Compared to a receiver, a frequency counter is a fairly low-sensitivity device. By design, a frequency counter operates mainly in the near-field region of a transmitter. (The near field translates to about a hundred feet for a 2 meter handheld.) This means that the strongest signal wins—and gets counted. How else could the counter differentiate between the hundreds of weak signals available between 5 Hz and 2.8 GHz bombarding its antenna?

> ***"This makes it very easy to capture frequencies without even looking at the display, eliminating the need to jot down frequencies as soon as they're counted."***

On the other hand, if the counter isn't sensitive enough, it won't be able to count a frequency until you're right on top of the transmitter. This would be okay for some test bench applications, but pretty useless for fox hunting or investigative work. The ATH-50's sensitivity varies with the frequency being counted, but for most of the bands of interest (10 - 800 MHz) the sensitivity is less than 2 mV.

This sensitivity represents a good compromise between the ability to count distant signals and the disadvantage of hearing too many signals so the counter becomes confused. Depending on your application you may choose to select a unit with a higher or lower sensitivity, or you might choose to add an accessory that will increase the "effective sensitivity" of the unit on a given band. We'll discuss those accessories later on.

Another feature to consider when buying a counter is the type of gating used. Gating is simply the counter's method of letting a certain amount of signal pass into the counter circuitry at a given time, in order to measure it properly. All counters use a hardware gating circuit that controls the gating based on signal level, just like high-end professional counters. This produces an extremely fast response time, on the order of 80 ms to gate, capture, count, and display an accurate frequency.

In contrast, some microprocessor-based counters use a sample-and-compare method, meaning that successive samples are compared until a match is found (or several matches in a row) and then the match is displayed as the correct frequency. While a valid method, the sample-and-compare counters can't match the fast response times of the hardware-gated counters. Again, this may not be a problem on the test bench, but it may be an issue when DFing a repeater jammer or tracking down an elusive intermod product.

It's easy to focus on the off-the-air performance of a frequency counter and totally forget the in-circuit uses of the device. Counters are quite handy for measuring the frequency of in-circuit oscillators, both in receivers and transmitters.

NEVER SAY DIE
Continued from page 35

I have so much I want to do that I could fill a 300-hour week. I've recently read some fabulous books I want to tell you about. And I've got a bunch more stacked up to read. I want to set up a small lab and do some research for a new product that every person in the world will want to buy. It's a product that will help every person who buys it to be healthier and live longer. The FDA will hate it, as will the AMA, the National Cancer Institute, the NIH, AIDS activists, the Medicare and Medicaid bureaucracy, and so on.

That's what I plan to do. Now, how about you?

Bug opportunity

I sure wish I had a bunch more readers like Alan Glowinski WA9EVE. Alan sent me some great newspaper clippings. One on several families whose kids died of leukemia from living near power lines, another on a micropower impulse radar

Continued on page 39

Unfortunately, you can't simply hook a scope probe up to your counter and start probing around in your receiver; the 50 ohm input impedance of the counter will load down the higher-impedance oscillator circuit, causing it to "pull" the crystal off frequency or kill the oscillations entirely. The ATH-50 has a special high-impedance mode on the 5 Hz to 50 MHz range that allows you to use the counter in-circuit, without disturbing the circuit under test. This 1 megohm impedance is the same value as that found on Tektronix scopes, and can be used under the same circumstances.

Don't forget the physical characteristics when considering a counter. The counters all sport high-efficiency, high-brightness LEDs. Easily readable from across the room, they're also readable in broad daylight—and they take the same or less current than comparable LCD counters.

The ATH-50 and all the models come packaged in anodized aluminum cases, utilizing threaded machine screw bushings. (If you expect to give it more abuse than the case can take, just pick up the optional carrying case.) And last but not least, always consider the worst case scenario. What if the thing breaks? All counters are covered by a 5 year parts / 1 year labor warranty - and the high-intensity LED's are covered for 5 years, parts and labor.

The frills

Once you've determined which basic frequency counter features are important to you, it's time to check out the more advanced features. The ATH-50 has several functions that make using it an enjoyable experience. The first of these is the built-in bar graph RF signal strength meter. While a field strength meter is nothing new, they have only recently begun to be incorporated in frequency counter designs. The field strength meters consist of a ten-segment LED bar graph, located right above the main display.

The bar graph display operates independently of the counter, and displays the level of the strongest signal present. Perhaps the most common use of this signal strength indicator is to tell the operator when the counter has enough signal for a good reading.

Another excellent use of the RF signal strength meter would be during a foxhunt. Small, lightweight, easy to see in the dark, quick responding—these counters would be great for use during the "end game" of the hunt. In addition to giving a field strength indication, the counter display will give a confirmation that you're homing in on the proper carrier, in those cases where the fox is hidden near a second transmitter.

The feature that makes the most difference in daily operation, and the one that really differentiates the ATH-50 from most bench-style counters, is the Automatic Trigger and Hold Circuitry. Rather than returning to zeros after displaying a signal, counters with the ATH function hold the last valid count until the next signal comes in.

This makes it very easy to capture frequencies without even looking at the display, eliminating the need to jot down frequencies as soon as they're counted. An automatic clean dropout feature ensures that a valid count is received before the last count is overwritten, to prevent "garbage" displays.

"Yikes! The local FM broadcast station was at this site!"

The ATH function, combined with the 80 ms response time of this counter, makes it possible to capture frequencies that would totally escape detection without these features. The ATH-50 also has a simple hold switch which locks the current display until the switch is changed, and a one-shot mode that operates in conjunction with the ATH mode except that it locks on and holds the first valid frequency, and holds that frequency until reset, regardless of subsequent signals.

The add-ons

It's time to consider the available accessories. The accessories most likely to enhance the operation of your counter are band pass filters. These small filters are installed in line with the counter's antenna, and pass a band of frequencies of interest.

Suppose you're trying to use a frequency counter at a crowded mountaintop radio site. You want to count the frequency of a 440 MHz ham repeater, but the frequency counter is confused. It hears the 440 MHz machine all right, but it also hears the 30 MHz paging transmitter, the 155 MHz police base, the 72 MHz RF link, and several of the 800 MHz cellular phone channels. By installing the proper band pass filter, most or all of these other signals can be reduced or eliminated, allowing the counter to produce a valid count on the band of choice.

Band pass filters are also useful for general off-the-air counting, anytime you know what band you're interested in. By eliminating signals in other bands the filters reduce the overall RF noise floor, improving the effective sensitivity of the counter for the frequency you're trying to count. In difficult situations, band pass filters can make the difference between a solid count and garbage. Startek offers four different filters: DC - 60 MHz; 130 - 500 MHz; 400 - 1500 MHz; and 800 - 2000 MHz models. Each of these offers less than 1 dB of insertion loss over the passband, and attenuates out-of-band signals by at least 25 dB, and much more on some bands.

As an example of the usefulness of these filters, I was recently called upon to track down some interference on a nearby mountain. The site was fairly crowded, radio-wise, and one of the commercial 450 MHz repeaters was trashing the 2 meter ham repeater, probably because someone had mounted the commercial rig's antenna right on top of the ham antenna. Unfortunately, we couldn't tell which one was the culprit.

At the site, I flipped on the Startek—it displayed 107.9. The LED bar graph showed six or seven segments lit—a pretty healthy signal. Yikes! The local FM broadcast station was at this site!

The bandpass filters would save the day. I reached into my pack and pulled out the HP-400, which passes frequencies in the 400 to 1500 MHz range. Putting this filter in line with the antenna dropped the signal strength to one or no bars, just about eliminating the FM broadcast signal. Now the 450 MHz commercial repeaters began popping up on the display, and I was able to quickly identify the rogue transmitter.

The performance of the counters can also be improved by using an antenna tuned to the frequency band of choice. Startek offers several antennas, as well as probes, cases, and a special interface cable for the MFJ-207 Analyzer.

Frequency counters have come a long way in the last few years, in terms of both features and pricing. The Startek ATH-50 represents the finest model in the line, and would make a good choice for anyone interested in a full-featured frequency. Designed and manufactured in the USA., the unit is available from Startek International, Inc., 398 NE 38th Street, Ft. Lauderdale FL 33334. 1-800-638-8050.

NEVER SAY DIE

Continued from page 37

system which presents endless opportunities for anyone with their antennas up looking for them. And a third, which is a real corker, on a new way to clean bacteria from water without using chemicals, heat or radiation.

This is a real simple approach which makes good sense and it's been tested and confirmed at Idaho University. So the answer to your first skeptical question is, yes, it really does work.

The process starts out by running the water through a pipe in the dark so that the bacteria shut down their defenses against ultraviolet light. Then you hit them with a 69 kHz high energy zap, which blows holes in their cell membranes. It rips the bacteria apart.

Applications: every home, swimming pools, reservoirs, public water supplies and so on. Imagine what a benefit this can be to third world countries where millions of people die every year from polluted water! There's even a hotel in Acapulco I could name that could use it in their restaurant.

Now, here's the test. Did you read the above, nod your head, and say how interesting that is; period? Or did you say to yourself, hey, there's one hell of an opportunity for almost anyone with some electronic smarts to make some bucks while helping a lot of people to keep from getting sick? Have I had any success at all in getting you to think like an entrepreneur or am I just wasting my time even trying to get you to make money and have more fun in life? Have you taken vows of poverty? Is it a religious thing?

Sigh.

In the last few days I've seen several outstanding opportunities to provide products that the world needs desperately. I just wish I had the time to make some of these things happen. For instance, one is a health product that would virtually guarantee that people could, if they had any interest, live at least 50% longer. Maybe 100%! It's inexpensive to make and could easily be set up with multilevel marketing thousands of people could make lots of money. And a few could make gobs. Watch out Bill Gates and Warren Buffet.

But I go to the trouble to read everything I can and learn about new fields. I seek out and talk with the experts, and then I go to scientific conferences so I can meet and talk with more experts. In the last year I didn't see you at the Boulder ISSSEEM conference in June. I was there. I didn't see enough of you at the Tesla Society conference in July in Colorado Springs, despite my editorials telling you about it. I was there and even gave a talk. Nor did I see you at the January '96 Global Sciences conference in Tampa, where two of the biggest technology breakthroughs of the 20th century were presented. And that isn't hyperbole.

Sure, Dayton is fun, but I can't remember when there has been one single talk there that got me to thinking and gave me ideas. If I missed any, nobody has bothered to write and tell me about it.

If you hear of any scientific conferences you think might

Debunking Some Myths about Antennas, Feedlines & SWR

14 facts to pass along.

Bill Parker W8DMR
2738 Floribunda Drive
Columbus OH 43209

If something is repeated often enough, it will be accepted as true. Incorrect information will never be extirpated, but we can all help to reduce it by being correctly informed and knowledgeable about transmission lines and antennas. Spreading myths and misconceptions about antennas over the radio, while newcomers are monitoring, is how wrong ideas propagate.

Read as much as you can absorb. Think about what the author is trying to convey. Compare different authors' ideas. Attend club meetings that offer programs about the subject. Sooner or later, when installing an antenna or while operating with an antenna system, conditions will occur that seem to defy any and all logical explanations. You will be glad then to seek advice from anyone who will listen to your woeful tale. Here are some facts to help you tell when a misconception is being repeated and believed to be accurate. At first glance they may be hard to accept, but facts they are.

1. A low SWR indication does not necessarily mean that everything is operating properly. It does indicate that the antenna system, consisting of the transmitter, feedline, and antenna, are very close to being properly impedance–matched. Changing frequency without some change in SWR is usually cause for concern.

2. Reflected power does not flow back into the transmitter causing overheating and/or inflicting damage. Mismatched impedance essentially detunes the amplifier allowing damage to occur.

3. No transmission line must be any specific length if a transmatch (antenna tuner) is available. Varying the length of the feedline doesn't change the SWR, but it does change the impedance presented to the feedline-tuner connection.

4. At frequencies below about 35 MHz, when using open wire (low loss) feedline, signal levels due to SWRs as high as about 6:1 will be essentially the same as signals produced by a near perfect 1:1 SWR.

5. Neither the antenna or the feedline must be self-resonant to operate properly. Nearly any feedline and associated antenna may be resonated by using an antenna tuner (transmatch).

6. Using a transmatch to resonate an antenna-feedline system does not change the antenna or the feedline impedances. It provides the required inductance/capacitance to resonate the mismatched antenna system, via reactance canceling, also referred to as conjugate impedance matching.

7. Most losses in an antenna system occur in the accompanying transmission line. The ohmic losses due to very small diameter conductors are an obvious exception. Nearly all antennas are quite efficient radiators.

8. For low-loss transmission line, an SWR meter placed anywhere in the line will read the same value. At the antenna, at the transmitter, or somewhere in between yields the same reading.

The Alpha Delta DX-A 160-80-40 meter Twin Sloper

Okay, so you don't have a 200 acre farm.

John Stevenson AC4JO
4576 Monaco Road
Memphis TN 38117-6132

The first thing you, as a new ham, should do, is sell your house and buy enough land so you can set up a decent antenna system. Since the XYL may inexplicably veto this very practical solution to your problem, some compromises may be necessary. My yard is only 55 x 100 feet, including two pecan trees and power lines, which made the top band contacts for 5B-DXCC difficult.

After trying dipoles, slopers, and reading every antenna article I could find, I gave up and bought an Alpha-Delta DX-A Twin Sloper at Dayton. It is designed for 40-80-160 meters, with one leg of the sloper a quarter wave for 80 meters and the other a quarter wave for 40. It has a coil partway down to provide a quarter wave on 160. Like all slopers, the wires make one half of the antenna and the tower makes the other half. The 80 meter leg is 67 feet long. The 40 and 160 section is 70 feet. The antenna is rated for full legal power and comes preassembled.

The instruction sheet made the installation simple. I installed the predrilled center connector as high on the tower as I could, with the wires stretched sloping to the ground. My lot's shape forced me to put the two elements at about a 90° angle rather than the 180° recommended. Using my MFJ Model 249 SWR Analyzer, I easily trimmed the antenna to resonance. Both sections resonated slightly below the band edge. After trimming, I was pleased to find the antenna was 1.5:1 from 1810 to 1850, from 3750 to 3850, and from 7050 to 7250. Out of curiosity I tried out 17 meters and found it resonant just above the band.

"The Alpha-Delta DX-A Twin Sloper is designed for 40-80-160 meters, with one leg of the sloper a quarter wave for 80 meters and the other a quarter wave for 40."

When I got on the air the first thing I heard was 9G1BS 5/9 working split on 7075 and 7175. I worked him on the first try and got a 5/9. Then, trying 80 meters, I worked VP5/JA7MQD and XE1L, with 5/9 both ways. The next day, using a Drake MN-2000 antenna tuner, DL4VCG/HC8 and VP2EE were weak, but workable on 17 meters. I'd say it's a darned good antenna!

The N1IR Tree Antenna

Yes, this is *the April issue...but this is a* real *antenna, not a joke!*

Chip Cohen N1IR
2 Ledgewood Place
Belmont MA 02178

This "biological antenna" may be the most peculiar antenna you'll ever hear of . . . and it works!

In the last few years, I have been designing and building a variety of new and exotic antennas; specifically in the field of fractal antennas, which are built around those exotic shapes showing up just about everywhere. The new antenna described here was inspired by some theoretical (model-based) work, in which mathematical "fractal trees" were found to be high gain antennas. Also, I was aware that real trees had been shown to be VLF resonators about 15 years ago. In *QST* I'd seen old reports of trees poorly resonating at 40m when tuner-fed. Would they work at *any* communications frequencies? I decided to put my scientific skepticism aside and let my curiosity take over.

Fact: Real live trees *are* antennas. But before you exchange your antenna farm for a tree farm, keep in mind that real trees are mediocre-to-good antennas which only seem to work at VHF and UHF. Here's how to "build" one.

"Real live trees* are *antennas."

First, find a tree 15 to 20 feet tall. Bring your coax to the ground at the foot of the tree and firmly hammer a 1-foot ground rod into the soil about 2 inches from the trunk. Attach the braid to the ground rod. The rod should only be visible an inch or two above the soil. Next, hammer a 1-inch nail into the trunk, about 2-4 inches up and close to the ground rod. Connect the center conductor onto the nail. If you wish, you may place a ferrite collar at the feed to assure that it's your tree that's radiating. See Photos A and B, which show my connection to a 20-foot oak tree, and the tree antenna itself.

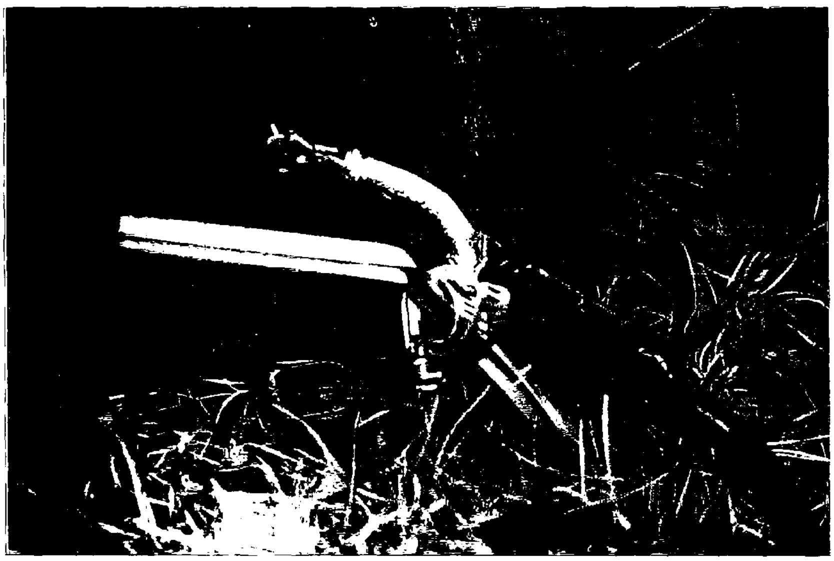

Photo A. *The author's connection to a 20-foot oak tree.*

Now go and operate. You will find that the "tree antenna" resonates broadly (less than 2:1 SWR) from about 120-175 MHz for a 50 ohm feed. It is mostly resistive, and not reactive, near 2m. You'll have a 2m antenna—without the antenna! The tree antenna seems to perform roughly 2 dB better than a 1/4-wave duckie (based on a direct comparison). Don't expect it to perform like a high ground plane, though—it will easily be 8-12 dB below even a modest, raised commercial ground plane vertical antenna. A true gain antenna it's not—but it's nature's free gift to the VHFer. Here, near Boston, my tree antenna is on a hill and I get into the Derry, NH, repeater (K1MNS) and the Carlisle, MA, repeater (W1FC) full-quieting with 1 watt. That's 40-45 miles away. Same story with DX packet on K1EA, which easily connects from 35 miles with a watt. My results may not be typical, though, because of my elevation. If there's a repeater 10-15 miles away, a tree antenna should be adequate in most locations.

To double-check my results I had to establish that it was the *tree* radiating, and not the coax (all of which was on the ground). I loaded the ground only; no dice. Then I disconnected the hot conductor from the tree and watched the signal go away. I fed the tree with different lengths of coax—from 1 inch to 100 feet—and noted the (minor) SWR changes. The MFJ 259 SWR analyzer

was handy for this. I minimized the length of unshielded coax at the feed to a few inches or less; a very high SWR would show *this* to be the radiator. Finally, I placed a ferrite collar on the coax at the tree to stop coaxial radiation, and then used an IC Engineering field strength meter on a pole to confirm that the radiation was emerging from the tree and not the ground. Maximum near-field readings came from the lower trunk and upper branches.

The tree seems to resonate by virtue of its height. This might also be expressed by its trunk diameter, since a thick trunk goes with a high tree. I found, roughly, that the resonant frequency goes as the formula:

$$f = 150\,(D)^{-0.20}\text{ MHz} \quad [1]$$

for D, the trunk diameter, in inches. The resonance is of very low Q. I measured a Q of about 3 for several different trees (mostly maples and oaks) . The lowest resonance I attained was about 100 MHz for a 1-1/2 foot (trunk diameter) oak tree. Keep in mind that I had no equipment capable of checking VLF resonances, just as I suspect that the previous investigations had not checked out VHF possibilities. The tree worked poorly when fed by a tuner on 40m and 20m; it was basically a dummy load at HF.

To explain the tree radiator, it is tempting to use fractal theory. Such a broad resonance radiator could easily be explained by a "multifractal spectrum," indicating that the real tree is not just one fractal pattern, but a variety of patterns akin to one another (clouds are a great example of something with a multifractal spectrum). It is not known to what degree the roots function as "radials." Further work needs to be done to show how the fractality of real trees affects their characteristics as antennas, if at all. Unlike the fractal tree antenna, the real tree antenna is capacitively loading the feed, and is not high in gain.

Why use a tree antenna? Aside from the novelty, a tree antenna is the ultimate stealth antenna. If your neighbor complains about a radiating tree, it's time to cart him off to the funny farm. Imagine the "no antenna" controversy in your town erupting over trees. Time to pull them all down—or defer to the intent of PRB-1! Seriously, though, it is a good emergency antenna, and may be useful for RC-controlled lawn and patio electronics, among other things. And will there be a tree-based repeater soon?

A few cautions: First, *never* use high power on the tree; it could result in a fire. Next, be aware that rain and snow will undoubtedly (temporarily) short out the antenna, or at least change the SWR. Ground conditions also change the resonant frequency, but the resonance is so broad that you will experience only minor 50Ω SWR changes (mine was 1.3:1 at 2M) after it rains.

***Photo B.** The tree antenna itself.*

"The tree antenna seems to perform roughly 2 dB better than a 1/4-wave duckie."

Also, if you *depend* on your VHF link, try a backup antenna (or make the tree your backup). Finally, I am not suggesting a new scientific field where you: "plug in a petunia," or "radiate the radishes." Anything that's water-based will radiate (or at least load)—usually poorly. Because they are tall, stationary, grounded, and don't complain, trees make the best "biological antennas."

On a practical note: *Trees are resonant structures*. Therefore, at VHF and UHF, it's best to get as far *above* and away from them as possible. Your backyard forest is not transparent to RF.

Does being an antenna do anything for the tree? Probably not. Note, however, that trees do *not* resonate well at LF, HF and MF. It is at these frequencies that much of the energy from lightning is discharged. Could being a poor low-frequency radiator help a tree survive lightning strikes? We will never know—unless trees start doing something bizarre, like talking back. And if they do....I'm not listening!

73 Review

The ISOTRON 80

Good things come in small packages.

Jim Bellini K9HKS
817 East 15th Street
Sterling IL 61081

As most of the ham radio community is aware, the amateur bands were not at their best during the months of October and November of 1995. So was that a good time to try to evaluate an antenna? Well, after thinking about it, I believe it was! If it will work under poor conditions we all know it is going to *really* perform under great conditions!

I received a letter from Ralph Bilal asking me if I would like to review one of his ISOTRON antennas and compare it to other antennas that I have had at this location. I jumped at the chance because I have seen the ISOTRON antennas advertised and, frankly, I thought that they were kind of an odd-looking antenna—too small to be effective and, at most, good for someone in an apartment, operating portable, or perhaps in a mobile home park. Was I surprised! (More about that later.)

Ralph said he would send me the ISOTRON 80 antenna, as I happen to be very active on 75 meter SSB. By the way, I have been a ham for about 40 years, so I think I have seen and tried almost every type of antenna that has come along. I especially like to make wire antennas: loops, longwire, dipoles, curtains, etc., and anything that is out of the ordinary. Looking at the picture of the ISOTRON 80, it certainly fits into the out-of-the-ordinary category!

Assembly

About a week passed and I was at home on my lunch break when the UPS truck pulled up. The driver handed me a box that looked too small to contain an 80 meter antenna and that felt as if it must be a box of feathers—it weighed scarcely 6 pounds! I quickly opened the box and, to my surprise, there was hardly anything in it that even came close to looking like an 80 meter antenna. Everything was neatly packaged; nothing rattled around in the box. In fact, each little package was secured to the box with some kind of epoxy. Looking at the contents I admit I kind of chuckled and thought: This is not going to be much of a test—it's too small to do much on this band.

Later that evening I read the assembly instructions and decided that since it was so small I would put it together in the basement. Downstairs we went and in about 20 minutes I had this strange-looking antenna put together.

"This antenna is not just something to use until you can get a* real *antenna—it truly is a real antenna and I would recommend it for any permanent station."

Operation

Well, what now? I had a 10-foot piece of coax so I decided to hook it to the antenna and my TS-440S. To my surprise, the signals were pretty good in spite of being in the basement with an antenna that didn't look like it would do anything on 75 meters (it looked more like a 2 meter antenna).

The next day I considered trying to get the antenna outside and on the tower, but there was about a week of windy, rainy weather, so there was no chance to work with the antenna. I kept looking at it and wondering if I was wasting my time, but my curiosity was getting the best of me. Out to the garage I went and found a couple of sections of TV mast pipe. I put them together and fastened the ISOTRON 80 to the mast pipe. The wind was still blowing and the temperature was around 25°F, so I had to make quick work of getting this antenna into a position where I could see if it would do anything at 20 feet.

Photo A. The ISOTRON 80. Photo by Will Sosa.

I took a couple of sawhorses and made a support to hold the 20 feet of mast and antenna up in the air in the middle of the back yard. It wasn't pretty, but at least it was off the ground.

Back to the basement and the rig. Signals were not bad considering the conditions. I wondered where the resonant frequency was going to be. According to the instructions, without the tuning stubs the antenna should come into resonance around the high end of the band. Much to my surprise, without any adjusting the resonant frequency was 3.940 with a 1.1 to 1. So would the signal get out when the antenna was only 20 feet off the ground?

I was able to work several stations with 58 59 57 reports in the middle of the afternoon. I was interested to see what the signals would be when I checked into the Mid States WX net meeting on 3.940 at 6 p.m. CST that evening. I have been on this net for many years and most of the fellows know what my signal should be. No one seemed to notice any difference in the signal! When I told them what I was using, there was the same disbelief that I had felt when I first saw the antenna.

Switching between the dipole and the ISOTRON, I noticed that the ISOTRON didn't seem to pick up as much noise as the dipole.

The dipole's and the ISOTRON's signals were comparable in the receiving mode. In transmitting, at some times the dipole would run about 1 to 2 S units stronger and at other times my signal was about the same. The

dipole was at 35 feet and the ISOTRON was at 20. I was impressed!

Performance

The next step was to get the ISOTRON up in the air on the tower. Finally. the forecast was for 50°F, so I decided to run a new line of RG58U coax to the tower. I asked the XYL to come out and hold the ropes while I went to the top of the tower, and in a couple of hours the ISOTRON was up at 57 feet. Now for the big test!

Into the shack I went to see if this little thing was really going to do much on the 75 meter SSB portion of the band. I checked again for the resonant frequency and found that the antenna had changed and was now resonant at a much lower frequency, 3.867, with a 1.4 to 1.0 SWR. I use a solid-state rig; I wanted to know what the band width would be as anything above a 2 to 1 SWR causes the output to be reduced. I found that I was at a 2 to 1 SWR at 3.893 on the high side of 3.867, and a 2 to 1 SWR at 3.843 on the low side of 3.867. By using the built-in antenna tuner I was able to cover the whole 80 meter band with no problem.

I am currently using a Kenwood TS-440ST driving a Dentron MLA-1200 amplifier with a Dentron Super Tuner. I was pleased to find that the ISOTRON accepted the 1,200 watts PEP without any problems. (It is rated at 1,000 watts PEP, 500 watts CW, according to the manufacturer.)

I am still stunned at the performance! It exceeded my *wildest* expectations—I was jumping in and out of different QSOs getting signal reports and comparing them to those of the dipole antenna; the ISOTRON was outperforming the dipole, which was mounted at 35 feet! I wondered if it favored a certain direction but found that it is omnidirectional, just as the Bilal Co. .said it would be.

In using the antenna over the past couple of weeks I have found that it has performed above and beyond what I thought would have been possible for such a compact antenna. I think the best report I have received so far was from WØNUJ in Coldsprings, MN, who gave me a report of 59+30, and K9TCC (about 12 miles from me) was running 59+15 with his dipole antenna. I have compared signals many times against the dipole and have found that on stations close in (75-100 miles) at times the dipole was slightly stronger by maybe 1 to 2 S-units. On stations worked over 100 miles the ISOTRON 80 has given me better signal reports.

Some other reviews that I have read of the ISOTRON antennas report that they make great antennas for those who live in restricted areas (apartments, mobile home parks), Field Day sites, or portable sites, and that they are a quick way to get a signal on the air. This is true, but I would like to say that this antenna is not just something to use until you can get a real antenna. This is truly a *real antenna* and I would recommend it for any permanent station.

"I can picture them all on one tower with no wires, control cables or antenna rotors."

How does it work?

How do the ISOTRONs work so well? For an antenna to work, it should be electrically resonant. The ISOTRONs are made electrically resonant by using only two components: the large coil in series with the capacitive plates of the antennas. (Match comes automatically with the right combination of the two components at resonance.)

There is more that is necessary for an efficient antenna. An antenna needs a certain amount of area to couple radiation to the atmosphere, sometimes referred to as the "capture area." However, this is an *area*. The area can be any shape or form. The laws of physics for this phenomenon do not specify appearance. The ISOTRONs have this radiation area. They exceed or equal (depending on the model) the area of a conventional half-wave dipole (#12 wire). In simple terms, the Bilal Co. has designed the ISOTRONs into a three-dimensional package. The performance speaks for itself! I'm pulling the dipole antenna down at this QTH and the ISOTRON 80 is going to be *the* antenna. In fact, I'm wondering about the other bands-160, 40, 20, 17, 15, and 10. I can picture them all on one tower with no wires, control cables or antenna rotors.

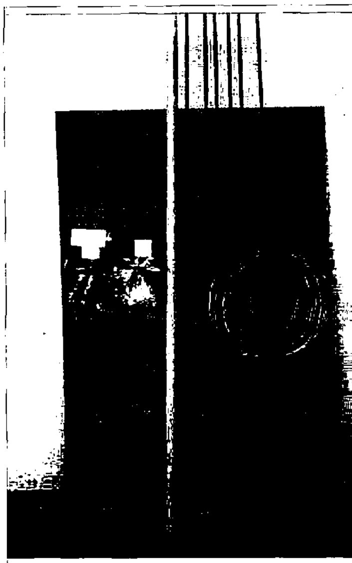
Cricket Pulser Eases Tuning Stress

If you want to tune your transmitter without running it at full power, Centaur Electronics offers the Cricket Pulser as a way of limiting wear and tear on your equipment without sacrificing tuning accuracy.

The pulser connects to the rig's CW key jack. Depress the pulse button and adjust the duty cycle for the desired pulse width. For example, if you set the pulse width at 10%, the 1.5 kW amplifier will think you are only running 150 watts, but the full power will be there in pulses, allowing you to use any relative or peak-reading watt meter to tune.

There's also a key-down switch to allow you to run continuous-power tests.

For more information, contact Centaur Electronics at 3720 S. Park Ave, #604, Tucson AZ 85713. Phone: (520) 622-6672. FAX: (520) 622-1341.



Antenna Kits from Cubex

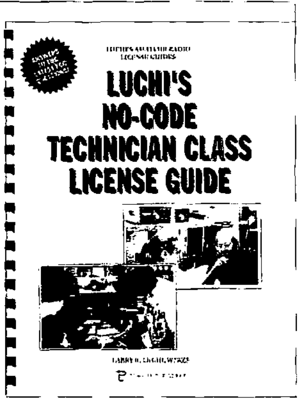
The Cubex Antenna Company has released two new VHF-UHF antenna experimenter kits. The kits contain all the parts needed to build experimental antennas customized for specific applications.

Each kit contains a Fiberglas boom, quarter-inch spreader arms, copper tinned antenna wire, antenna wire notches, insulated feed block, PVC or aluminum boom mast coupler plate and miscellaneous stainless steel hardware.

The kits come in two boom sizes: either 4 feet by 1 inch, or 8 feet by 1.25. The four-foot version costs $29.95 plus $6 shipping, and the eight-foot goes for $69.95 plus $12 shipping and handling.

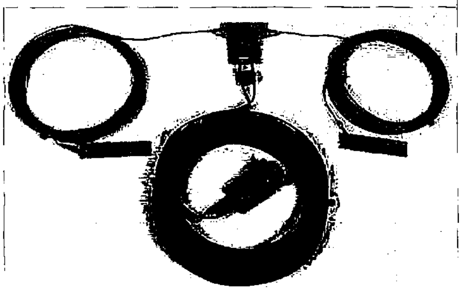
The address is Cubex, 2716 Sturn St. Unit E. Brea CA 92621. Phone (714) 577-9009. FAX: (714) 577-9124

No-Code Tech Class License Guide



Larry Luchi W7KZE has been at it again with this 160-page 1995 edition of his Tech license guide. Latest question pool. Answers. And good explanations so you can take the test understanding what it's all about instead of trying to memorize hundreds of Qs & As. None of this stuff is very difficult to learn, and you'll need to have a good grasp of the fundamentals to go on to your General license. Unless, of course, you are a gutless, wishy-washy, namby-pamby dullard with no ambition to do anything but kerchunk our 2m repeaters, thus settling for about 1 percent of the adventure amateur radio has in store. No offense intended. Tiare Publications, Box. 493, Geneva Lake WI 53147.

A New Price On an Old Favorite

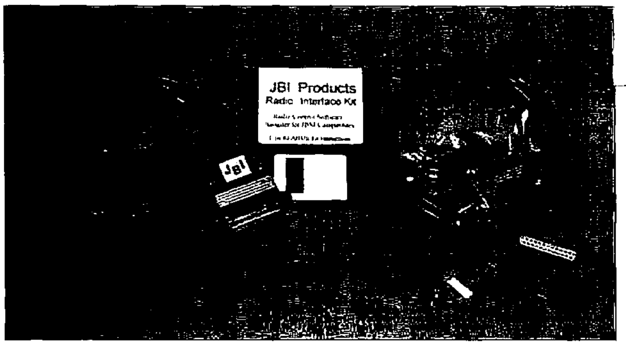


MFJ Enterprises has managed to cut the price of the old reliable G5RV antenna to less than $30. The MFJ-1778 is the latest version of this popular wire all-band antenna.

The antenna is just 102 feet in length – less than the length of a full-sized 80-meter dipole. As a sloper or an inverted vee, it's even more compact. With an antenna tuner, you can operate from 80 through 10 meters. With an antenna tuner and a ground, it will even operate on 160 meters.

MFJ's version of this antenna comes fully assembled and ready to handle full legal power for $29.95. The setup includes 102 feet of antenna wire, 32 feet, 6 inches of 450-ohm ladderline terminated with an SO-239 coaxial connector.

The address is: MFJ Enterprises Inc., PO Box 494, Mississippi State MS 39762. Phone: (601) 323-5869.



Computer-Transceiver Link Announced

JBI Products and Technologies has announced a new computer-radio interface that allows hams to control their radio equipment with a PC compatible computer.

The interface works with units by Kenwood, Yaesu, Icom, Heathkit and Ten-Tec that are designed for computer control.

Johnson Matchbox

Continued from page 28

four narrow plastic spreaders which run the whole length of the coil. They are located every 90° around the circumference of the coil.

The main coil is tapped at approximately 0, 8.8, 12.7, 14.6 and 15.5 turns from each end; the tap at 0 turns means that the entire coil is used. This gives 80 through 10 meter coverage, respectively. 17 and 12 meters are covered but not 30 meters. 30 meter coverage could be provided by an additional tap between the 40 and 20 meter taps.

Link Coil

Wound over the center section of the main coil is an unbalanced input link coil (L2).

The link is wound with the just about same pitch as the center section of the main coil. However, its outside diameter is larger, 3.0 inches. It contains four turns.

The link coil is positioned coaxially with and over the center portion of the main coil. It has an adjustable tap—about 1.25 turns up from ground gives around 50 ohms output impedance. Using all the turns of the link gives in excess of 300 ohms impedance.

Both coils and all the wiring is made from 12-gauge, tinned, solid-copper wire.

Switch

The switch (S1) for selecting coil taps is a rotary unit. It has two poles with five positions (Johnson No. 22.884). It is a successively shorting design, although I'm not sure if this is strictly necessary. The switch is not large—it's about 1.75 inches in diameter. The two switch sections are located on opposite sides of 3/16-inch thick ceramic insulation. In my home-brew version, I just used alligator clips to tap the coil.

Capacitors

There are two variable capacitors. They are both rated at 3 kV peak using 0.075 inch plate spacing and ceramic insulation.

The first one (C1) is an ordinary dual gang unit, with 10 to 100 pF of capacitance per section (Johnson Part No. 154-505-4 [100ED30]).

The other capacitor (C2) is set up as a two gang, dual differential variable, also 10 to 100 pF per section (Johnson Part No.169-25 (100EDA30)). Adjusting a dual differential capacitor causes one section to increase in capacitance while the other section decreases. For example, as the capacitance of section C2a is increased, that of section C2b will decrease (ditto for sections C2d and C2c, respectively). For this circuit, the rotor of this capacitor needs to be insulated from the chassis.

My home-brew version of the Matchbox was built on a metal plate resting on a wooden chassis. The manufactured version comes in a 10 x 10 x 8-inch high metal box.

Tuning Up

Tune up is simple. Install an SWR bridge between the transmitter and the matchbox with short pieces of coaxial cable. Select the correct coil tap for the band to be used. Using the lowest possible power input to get an SWR indication, juggle both variable capacitors for the lowest SWR. There is interaction between the capacitor adjustments.

Or, to be more considerate of others on the air, connect an antenna noise bridge to a receiver. Set the noise bridge to 50 ohms resistive, then adjust the tuner for a dip in noise in the receiver.

Performance

Using my particular antenna (a 275-foot long closed loop, roughly triangular in shape, approximately parallel to and about 25 feet above the earth, fed with 25 feet of home made 600 ohm open-wire line), I'm able to achieve very nearly a 1:1 SWR on all bands. Current balance, as indicated by an RF ammeter in each leg of feed line to the tuner, is excellent though my loop is not symmetrical. The Matchbox circuit provides at least 15 dB of harmonic attenuation as it is a resonance circuit. It gives some preselection for the receiver as well. You'll realize this when you have to retune every several hundred kHz or so on 80 and 40 meters if you want to keep the SWR low. I don't find this a serious inconvenience, since I made up a calibration chart giving frequency vs. dial setting.

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
P. O. Box 473
Stevenson MD 21153

The accumulated showers of e-mail and letters this month are threatening to make a messy desk messier, if that is possible. So, let's look at what some of you have had to say.

Evaristo F. Nievera N2MBC enjoyed the review of ham radio Internet sites in the October RTTY Loop, and writes that he is just learning the ropes of the Internet, and had looked everywhere for amateur radio sites or home pages, only to find the information here in RTTY Loop. Formerly DU1EN, Rickey received his U.S. call five years ago and continues to stay in touch with Philippine news through the Internet. He has tried several of the commercial services, including CompuServe, Prodigy, and America Online, but prefers a direct connection through an Internet Service Provider for economy and speed of transmission.

He adds that since we are in the bottom of the sunspot cycle, with propagation at a long-time low, the Internet presents a threat to amateur radio. His current activities include packet and PACTOR, and he is looking into color transmission with PACTOR.

Well, Rickey, while I share your concerns about computer communication affecting amateur radio, perhaps the death knell is a bit premature. After all, the same could have been said of the telephone, other broadcast media, or even, as once was forecast, the citizen's band. But we're all still here. With new frontiers to conquer, and new techniques to explore, I think ham radio will lead us into the next millennium.

Then there was all the input on the question of sound boards and digital modes. Johan Forrer KC7WW fills us in on the origin of a term questioned in a previous column. "PSA" stands for "Personal Sound Architecture" and was coined by Analog Devices for a three-chip set: an ISA bus interface chip, a 16-bit stereo CODEC (the ubiquitous AD1848), and a ADSP-21xx family DSP chip. Several sound board manufacturers have used these on their sound boards. Unfortunately, this technology has already been made obsolete by the introduction of newer versions of the chipset. Echo Speech Corp, for example, now has the latest ADSP-2181 and a new ISA interface that offers WIN95 plug and play hardware and software.

Meanwhile, Rob Glassey GØVTQ (Robert.Glassey@nmp.nokia.com) writes the following: "I've been corresponding with Erwin Cremers about DSP software using a Soundblaster™ card and he mentioned you as someone who may be working on this kind of software. I'm interested in corresponding with anyone working in this field, since I am writing Soundblaster DSP programs too. My current project is a Soundblaster-based Ham Radio HF data modem. So far I have written code to demodulate RTTY to the screen, with tuning and input level indicators. This works, but is still in the very early stages. My ultimate aim is to TX/RX RTTY, AMTOR, PACTOR and possibly PACTOR II, both FEC and ARQ modes. I'd also like to try out some highly robust modes such as the second generation of CCW/BPSK for extremely low SNR comms (portable QRP DX)."

While I am not working on such a project, I am reasonably sure that at least one of the readers of this column (other than you) is., so I look forward to the establishment of a match, and feedback of any progress. Good luck.

One of the wonders of amateur radio is the international nature of the hobby. A site for "serious DXers" can be found at: http://promet12.cineca.it/htdx/—Mirko Caserta, IKØZSN, is the "Awards Page" manager. These pages contain the latest information about Italian Ham Awards, along with plenty of details about satellites, DX news, contests, and the like. This is both an attractive and useful page. Check it out.

Mark Walker N9HCI wrote that he was troubled with the version of Hamcomm he was using. "Got a copy off the net, looks really neat, except the tones do not go high enough to be usable. 2000 Hz is the top end for the generated tones. Any ideas? My only other choice is an old TU I have which generates RS232 on RECV OK, but would require some means to modulate the 120mA loop with the ±12v from the serial port's TXD line. Any sources you may recommend would be appreciated. Mark."

I dropped Mark a note telling him that the actual tones should not matter... just the difference between them. Not knowing which version of Hamcomm he had, I sent him version 2.2, which is on disk #5 of the RTTY Loop Software Collection, to try out.

His response: "The new Hamcomm works great." The moral? If a version of the software you are trying does not seem to work, look around for a new version.

An unsolved problem comes from Dave N3AAT, who notes that he has a Delta 2/Level Controller and Macintosh Portable. He wants to know what he has to do to get onto RTTY, whether he needs a controller, or if there is a software solution.

On a related note, Bob Castaneda KC7QR asks: "Maybe you can point me in the proper direction? I'm looking for a "good" RTTY program for this Macintosh Centris-650 computer that I'm now using. And maybe (but down the line) an SSTV program that will work on this too. I've been a ham since about 1972 and for most of that time it's been on RTTY. Have worked WAS, WAC, DXCC-RTTY, and some other stuff, most of it on the "old" model 15s and 19s. Found an excellent program for the Apple IIe computer for RTTY but don't have much room here in this small shack for more than one computer, so would like to find an RTTY program for the Mac. But if I can't find one, I guess I'll just have to hook up the old He again, huh? Hi."

Well, guys, unfortunately, I have very little Mac software. I know there is quite a bit out there, though. You might check on AOL, in the Ham SIG library, or on CompuServe, in HamNet. By now, I shouldn't have to hint to share the findings with us over here, should I?

Ray Ortgiesen WF1B advises: "I think folks interested in the RTTY loop page may want to surf (oh I hate that word) over to my page. It's got some assorted RTTY stuff on it. http://ids.net/~wf1b/home.html is Ray's site. Check it out, you may well enjoy it."

Speaking of Web sites, there is the home page of RTTY Loop at http://www2.ari.net/ajr/rtty/. One of the more popular features of the page is the library of old columns. Bill Howell N5ALO asks if it would be possible to have access to earlier issues? "If these are just sitting around on disk somewhere, wouldn't it be easy to plug them into the Web page?" Yes, Bill, it would be easy, but space consuming, and I have a limited amount of space on my server. I am trying to put up columns, downloads, and information useful to the readers of the column. Feel free to drop me a line, via e-mail or snailmail, if you have any suggestions.

Luis XE2MXU/N5UHB passes along his congratulations on the new web page. "It's good to see that at least one of the columns of *73* is on the web now. Now if we could get the rest of the magazine in there..:)" I can't speak for the rest of the magazine, Luis, but I look forward to sharing with all of you this way for a long time to come.

We've covered the past and future this month, along with plenty of your input. I always look forward to your cards, letters, and e-mail. Reach me via snailmail at the post office box above, or via e-mail at ajr@ari.net, MarcWA3AJR on America Online, or 75036,2501 on CompuServe. More next month, with plans to highlight some recent RTTY and related equipment.

Hams with Class

Carole Perry WB2MGP
Media Mentors Inc.
P.O. Box 131646
Staten Island NY 10313-0006

Technology and no life

I recently read a terrific article written by one of my favorite writers: Unknown. I chuckled so long and hard over the truisms that I decided to share them in my "Hams With Class" column. I'm sure that teachers and instructors of amateur radio who read my column will find appropriate use for this "ice-breaker."

You know technology has taken over your life when:

1. You have never sat through an entire movie without at least one device on your body beeping or buzzing.

2. Your stationery is more cluttered than Warren Beatty's address book. The letterhead lists a fax number, e-mail addresses for two on-line services, and your Internet address, which spreads across the width of the letterhead and continues to the back. In essence, you have conceded that the first page of anything you write *is* letterhead.

3. You need to fill out a form that must be typewritten, but you can't because there isn't one typewriter in your house....only computers with laser printers.

4. You think of the gadgets in your office as "friends," but you forget to send your mother a birthday card.

5. You disdain people who use low baud rates.

6. You use the phrase "digital compression" in a conversation without thinking how strange your mouth feels when you say it.

7. When you go into a computer store, you eavesdrop on a salesperson talking with customers....and you butt in to correct him and spend the next 20 minutes answering the customers' questions, while the salesperson stands by silently, nodding his head.

8. You know Bill Gates' e-mail address, but you have to look up your own Social Security number.

9. You sign Christmas cards by putting :-) next to your signature.

10. Off the top of your head, you can think of 19 keystroke symbols that are far more clever than :-)

11. You back up your data every day.

12. You think jokes about being unable to program a VCR are stupid.

13. On vacation, you are reading a computer manual and turning the pages faster than everyone else who is reading John Grisham novels.

14. The thought that a CD could refer to finance or to music rarely enters your mind.

15. You go to computer trade shows and map out your path of the exhibit hall in advance. But you cannot give someone directions to your own house without looking up the street names.

16. You would rather get more dots per inch than miles per gallon.

17. Al Gore strikes you as an "intriguing" fellow.

18. You own a set of itty-bitty screwdrivers, and you actually know where they are.

19. While contemporaries swap stories about their recent hernia surgeries, you compare mouse-induced index finger strain with a 9 year old.

20. You are so knowledgeable about technology that you feel secure enough to say "I don't know" when someone asks you a technology question, instead of feeling compelled to make something up.

21. You rotate your screen savers more frequently than your automobile tires.

22. You have a functioning home copier machine, but every toaster you own turns bread into charcoal.

23. You have ended friendships because of irreconcilably different opinions about which is better—the track ball or the track *pad*.

24. You e-mail this message to your friends over the net. You'd never get around to showing it to them in person, or reading it to them over the phone. In fact, you have probably never met most of these people face-to-face.

25. You understand all the jokes in this message. If so, my friend, technology has taken over your life. I suggest, that for your own good, you go lie under a tree and write a haiku. And don't use a laptop. 73

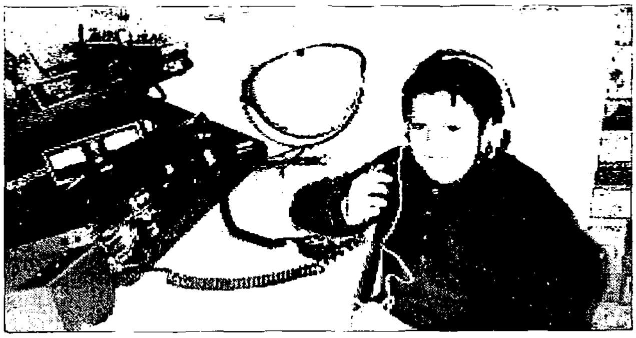

Photo A. *When working with students, try to keep them "balanced" so that technology doesn't take over their lives.*

HOMING IN

Homing In Radio Direction Finding

Joe Moell P.E. KOOV
PO Box 2508
Fullerton, CA 92633

Foxhunting the European way

According to a documentary I saw on "The Learning Channel," the urge to find hidden objects dates back to early civilizations. The children's game of hide-and-seek was played in ancient cities. So perhaps we hams are following a primitive instinct when we set out on hidden-transmitter hunts. Or maybe we are just satisfying our natural urge to compete.

Modern-day T-hunts, as they are called in the USA, usually involve a car full of radio direction finding (RDF) equipment and hours of driving, depending on the hunt rules. Over the years, vehicular T-hunting has gained popularity in England, Australia, and Japan. Elsewhere in Europe and eastern Asia, amateur RDF contesting (ARDF) is just as popular, but nobody uses a vehicle.

While our mobile T-hunts frequently require RDF on foot (called "sniffing") to track down a T that may be a few dozen yards from the road, it's usually a "sniff" from beginning to end in other countries. The international on-foot style of ARDF goes by such names as foxhunting, fox-teering, and fox-tailing. Though it is a sport for all ages, many cities in eastern Europe and Asia include foxhunting as part of Physical Education in schools.

Rules and preferences vary from country to country, but in most cases three to seven transmitters (foxes) are placed in a rural area of 200 to 2,000 acres. They transmit for a minute each, in numbered sequence. CW on 80 meters and AM on 2 meters are the most popular signals to hunt. Runners with direction finding equipment attempt to find all foxes, or as many as they can, then reach the finish line in the shortest possible time. Scores are determined first by number of foxes found and second by elapsed time. Sometimes bright orange and white orienteering flags (called prisms) are placed near the foxes to insure that they are visible. Other groups think prisms are for sissies and allow foxes to be concealed or even buried.

Detailed topographical maps are provided to all competitors to aid them in navigation and bearing-plotting. The sport is so popular in so many countries that regional, national, and international championships are held regularly. To this end, a standard set of rules has been developed by a committee of the International Amateur Radio Union (IARU) to specify the number of foxes, course size, age/sex divisions, fox timing, and the use of prisms.

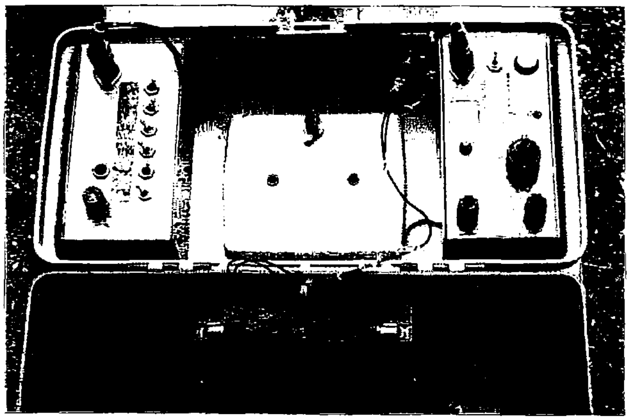

Photo A. This Swedish 80 meter fox transmitter is built into a small toolbox. The timer is designed to be synchronized with six other foxes and can be set several hours in advance. The empty space is useful for storing the antenna wires.

Bavarian beacons beckon

Ewald Stadler DJ2UE of Herrenberg is a very active promoter of ARDF. As a foxhunt organizer for the Deutscher Amateur Radio Club (a national organization in Germany that is similar to our ARRL), he is responsible for competitions of all the local clubs in his district. DARC has an entire subdivision for ARDF; its annual foxhunt calendar includes over 60 formal events.

"In Western Europe we do foxhunting as a club activity," Ewald told me. "It is for all ages. We have between 20 and 70 people coming to each competition. Most of them are over age 30. We also do mobile hunting, but that is in a different division. We don't like the mobilers because they make too much dirt in the air. Vehicle hunts are declining because of problems like road congestion."

DJ2UE continues, "At our contests we always hunt 80 meters in the morning and 2 meters in the afternoon, except for our championships when we have them on two separate days. On 80 meters, you have to know your equipment, the null and front-to-back ratio. But mostly it's running, a sport competition. However on 2 meters, it's a brain competition. You have to be very careful what you do because of the signal reflections. On 80 meters you can stand still and navigate and take your bearing and then go, but on 2 meters, no way! If you stand still and take a bearing, you may be off by 30 degrees."

Vertically polarized longwire fox antennas are the rule on 80 meters, but it's different on 2 meters. According to Ewald, "For VHF foxhunting in the forest, you can't use vertical polarization. The trees are all reflectors, and if you hide it well with vertical, you'll never find it. So we use horizontal polarization. For a four-mile course, it usually takes me an hour to find all foxes. Some hunters take two or three hours depending on how difficult it is. When I hide, I usually make it easy and I don't use very hilly country.

"A problem with foxhunting in Germany is that if you have a large group, say 70 people, they tend to follow one other and it's not a true competition. To solve this we sometimes scatter dozens of little 100 milliwatt 80 meter transmitters in the grass, each with an aerial of about 1 foot length. They transmit only a few feet, so you can find them only when you are close. I draw circles on the map where these transmitters are hidden. Hunters use the map to run to these circles and once inside them they navigate for the fox."

Swedes do it in the woods

There is more foxhunting activity to be found in Sweden than in any other country in Scandinavia. The last IARU World ARDF Championships were held there in 1994. My wife April and I had the pleasure of visiting this beautiful country last summer, where we were welcomed by Per-Axel Nordwaeger SMØBGU and Lars Nordgren SMØOY. Per-Axel, who was the main organizer of the 1994 Championships, took us to a typical forest near Stockholm, where he showed how their weekly foxhunts are done.

P-A, as his friends call him, explained the history of hidden transmitter hunts in his country. "In the 1960s we had something called a triple hunt with two or three people in the car; one to drive, one to read the map, and a third to do the receivers. Today gasoline is about a dollar a liter, so we always do ARDF by running."

NO TRESPASSING signs are the bane of transmitter hiders in the USA. Not so in Sweden, where there is a principle of law called *Allemansratten* (Everyman's Right). It allows every person to move about freely on foot in forests and fields, without worrying about property lines. They can swim, sail, and motorboat on lakes or rivers, and even make camp with a campfire for a night without permission from the landowner. Allemansratten provides Swedish foxhunters with their choice of hundreds of forest locations for ARDF contests, so long as they take care to pick up litter and protect the vegetation.

Swedish forests are a paradise for orienteering enthusiasts because they are hilly with extremely thick vegetation. Often you can't see more than a few feet in any direction. They are full of lakes and swamps. Much of the ground is

covered with small stones. It's hard enough to imagine finding your way in terrain like this in the daytime, but the intrepid Stockholm area foxhunters do it at night! Seven foxes start transmitting at 7:10 p.m. each Wednesday from May to late September. During spring and fall, this is after sunset. P-A says he wears a helmet with a 30 watt halogen headlight on it to help find his way during night hunts.

find 2 meters very interesting because it's so unpredictable," he says. "You end up in many places other than where the transmitter really is."

Simple Swedish 80 meter foxes (see Photo A) use inexpensive color TV subcarrier crystals, putting them on 3580 kHz. A rope thrown over a tree hoists the longwire antenna with one or two ground planes underneath.

"What a wonderful way to let children and teenagers know that computers aren't the only way to have fun with electronics."

"We also come together on a Sunday morning for what we call a national competition," says SMØBGU. "That means that one club organizes a hunt to which other clubs are invited. We use no prisms. Foxes are concealed under leaves or branches. In Gothenberg, they dig down into the ground and bury them. It takes about five hours to put out all seven foxes before a hunt.

"We are not allowed to run in the forest with short pants and shirts," P-A continues. "That is due to an epidemic about 15 years ago of hepatitis, or something similar. Nobody could figure out why only orienteers got the disease. Then they noticed that many competitors ran through the same paths in the forest and got scratches from bushes. Doctors suspected that blood was getting on the branches and being transferred from one runner to another. We changed the clothing requirement and it totally solved the problem.

"During previous World Championships, youngsters from Korea and Japan ran with nearly no clothing at all, even though it was cold with snow. So when we sent out information on our 1994 competition, we included a picture of a runner dressed the proper way so they would understand that someone not fully clothed would not be allowed to run. No one came dressed improperly."

Follow the bouncing signal

Almost all Stockholm area hunts are on 80 meters. P-A dislikes the signal reflections that plague VHF hunts. "I don't

P-A says skywave propagation causes problems during nighttime hunts. "Strong Italian signals sometimes cover our fox signals at the start point. We have to run into the forest and hope we hear them." According to SMØBGU, most hunters use the same receiver design, which is about the size of a cigarette pack (see Photo B). "Two Swedish radio amateurs started building them around 1965," he says. "It has been developed over the years. We can buy them either complete or in parts. The ferrite loop is quite OK. Lars uses a larger loop instead. It is heavier to carry, but gets a sharper bearing null.

"The old-fashioned receivers interfered with each other, so we had to spread the hunters out. Our hunters scatter into the forest two minutes before the first fox comes on. They are allowed to continue to search for two minutes after the last transmitter shuts off. About an hour after the hunt ends, the foxes automatically start transmitting again to help the organizer find them to pick them up."

Each fox has a crystal-controlled timer that P-A says is easy to synchronize. "Using switches, I can choose how many hours and minutes prior to start I will begin the timing. When I have exactly the selected number of hours to go, I run the cable into each fox and push the start button. It starts all the transmitters to count down to zero and then count forward. The display shows actual foxhunt run time. We trust hunters to write down the correct time on their card when they find a fox."

A toolbox-sized container with wires and timer display might look suspicious to a non-ham in the woods. "We had a competition outside Stockholm not far from the new royal castle," SMØBGU recalls. "On that island is the most secret radio installation in Sweden. This competition was very close to that area. We stopped hearing one of the transmitters and went to investigate. It was on a peninsula in a very swampy area between the mainland and the island. Normally nobody would go out there except silly foxhunters, but two young girls came out in a canoe and happened to find it. They didn't know what it was, so they rolled up the antennas and took it home to daddy.

"I had to go to the police to report the theft because it was close to the military installation. In the meantime, the organizer put flyers on lampposts around the area. One happened to be in front of the house where the girls lived. The homeowner saw it and we got it back, but it took a week. Now we put signs on the foxes."

The world awaits us

International-style foxhunting sounds like a great sport, doesn't it? What a wonderful way to let children and teenagers know that computers aren't the only way to have fun with electronics. Since publication of my "Homing In" columns about Hamcon/Foxhunt-95 in Southern California last fall, I have heard from hams who are planning to hold on-foot RDF contests like this in such diverse places as Pittsburgh PA, Daytona Beach FL, Portland OR, and Victoria BC. What about your town?

Organizers of European and Asian ARDF competitions are eager to have entrants from North America. To that end, they have established a special Promoters section in each championship, for countries such as the USA that have never participated in any international ARDF event. Each first-time IARU society may send a maximum of six competitors for the Promoters section, which will have its own special awards.

Photo B. Per-Axel Nordwaeger SMØBGU demonstrates how foxhunters get bearings on 80-meter signals in Swedish forests.

The 1996 IARU Region 3 Championships will be held in Townsville, North Queensland, Australia from July 15 to 20. The 1996 European Championships will be September 1 to 6 in Bulgaria, 45 miles south of Sofia in the Rila Mountains. The next IARU World ARDF Championships will be in 1997, probably in Germany or China. If you would like to attend any of these events and can finance your own transportation to the host country, contact me for information on how to register.

If you're going on a foxhunt in a foreign country, it wouldn't hurt to listen to some language instruction tapes before you go. April and I were pleased to discover that the majority of Swedes know conversational English. However, there are exceptions. SMØBGU tells this story from the 1994 championships: "One of the competitors got lost and ran all the way through the 2 meter area into the 80 meter area. When he realized the problem, he found the main road and stopped a car. He only knew one Swedish word, which meant 'engineers' for the engineering regiment where the competition was headquartered. Unfortunately, he pronounced it wrong and it sounded like another Swedish word that means 'nothing.' The driver couldn't understand him, so he took him to a police station. Fortunately, the police knew what we were up to, so they called the regiment and we sent a car to pick him up."

Keep your cards, letters, and e-mail coming. "Homing In" readers want to know what's new in RDF contesting in your area. Write to the address atop this article or send e-mail to me at Homingin@aol.com or 75236.2165@compuserve.com.

The end of monitors

For the past couple of months, we've been exploring the repair of dead computer monitors. Let's see if we can finish that up, so next time we can get into something else.

Set 'em up

With any luck, the past few months' columns have helped you to get that dead monitor running. If it's a few years old, though, you may be less than satisfied with the picture. Oh, sure, it was exhilarating to see it finally work at all, but now you want it to work *right*. Setting up a color display isn't hard, but it seems to be a dying art, and is probably one of the least understood procedures these days. I've even met some TV servicers who weren't clear on how to do it.

The elements

The basic elements you have to adjust are image size, geometry, brightness, black level, color balance, color tracking and focus. Wow, that sounds like a lot, doesn't it? Really, it doesn't take long, because some of the adjustments help set some of the others. Let's dive in!

Before we start, I must repeat my previous warning: The insides of TV sets are mighty dangerous! When you're poking your screwdriver inside to get at a control, it is remarkably easy for your hand to touch something. If that something happens to have plenty of voltage on it, you're in trouble. To help avoid disaster, remove your wristwatch and jewelry. If you have any rubber gloves, wearing them can really help. Just be sure to keep your eye on the part of your hand that *isn't* near what you're aiming for, as well as what is. And, of course, wear shoes: the less grounded you are, the safer you are. The old TV shop maxim of putting one hand behind you is still good advice, too, because it prevents your getting shocked across your chest, which is the most dangerous path in your body.

Now that I've terrified you, let's get started. Hook the monitor to your computer and set it up for an average picture. On a *DOS* machine, that would be text; in *Windows*, perhaps the program manager area. On a Mac, the normal desktop is best.

The very first adjustment you need to set is the image size. Unlike on normal TV sets, computer monitors deliberately leave some black area around the edges of the picture, because things can get too fuzzy if the scan goes all the way to the edge of the tube. Typically, 1/4" to 1/2" will be left black. If your monitor looks otherwise, snoop around the PC board until you find the vertical size control. Adjust it until the picture fills all but that desired black border, from top to bottom. If the black areas at the top and bottom are not equal, find the vertical centering control and get the image centered. To set the width, look on the board, in the area of the flyback. Now and then you might find a trimpot for width, but most width controls are coils with ferrite slugs. The coil may not be labeled, but it will probably be the only one in that area of the circuit. Try adjusting it carefully to see if the width changes. (Be sure to use a plastic coil tool, not a screwdriver; if you crack the core, you have a problem on your hands.) Set the width for about the same black areas on the picture's sides that you have on the top and bottom.

If the image is off-center, the obvious solution would seem to be to adjust the horizontal centering control. Most sets do have one, although sometimes it's a jumper wire and three pins you can plug it into, rather than a pot. Before you change any of that, though, look for a trimpot labeled "horizontal phase," or sometimes just "phase." Try that one first, as it will have a bigger effect. Usually, the centering control will be set correctly when it's fairly close to the center of its range.

If the picture looks pretty square, you don't need to mess with the geometry. If the sides bow in or out a great deal, though, look for a control labeled "pin" or "pincushion." Adjusting it will have an obvious effect. You may also find one called "trapezoid," the setting of which will also be pretty obvious. Geometry controls are always a compromise: don't expect to ever get a perfectly square scan on the curved surface of a CRT.

Lookin' good!

Now that your picture is the right size and shape, it's time to set something called the "screen." This is an overall bias adjustment that sets the amount of current which will pass through the CRT, from the electron gun to the phosphor screen, and it affects all three colors (red, green and blue) at the same time. Its primary effect is to fix the black level of your picture; set it too high and your blacks will be gray, too low and your bright areas will be weak and dingy. You'll find the control on the side of the flyback transformer, usually right near the focus control. Be sure to use an *insulated* screwdriver, as the voltages around the flyback are in the thousands. To set the screen control correctly, turn the brightness and contrast all the way down. Now, get a flashlight, and turn the room lights off. Use the flashlight to get your screwdriver in position. Observe the picture, and turn the screen control until you can just see a very dim image. If it looks discolored, don't worry about that just now.

Next, turn the brightness and contrast up to a bit higher than normal viewing levels. Adjust the focus control for best focus at the center of the image, while keeping an eye on the corners of the screen. Small changes in the focus setting will have much more effect at the picture's edges than in the middle, and sometimes you have to compromise a little bit in order to get uniform focus. If the edges won't come into sharp focus no matter what you do, you have to accept that it's the best the monitor can do. Age and condition of the CRT can greatly affect edge focus, and some monitors don't focus well at the edges even when they're brand new. Do the best you can. Generally, PCs demand less of their monitors' focus than do Macs, which present considerably more information on the screen. I've fixed many monitors that looked great on my 386 but awful on my Mac.

Black and white in color

Believe it or not, the best test of a color monitor is how well it can make black and white! Let the monitor warm up for at least 15 minutes, and then set your computer for a black and white image on the screen. If the gray areas look gray, with little or no coloration, you're all done. I'm not talking about fringes of color around objects—that indicates misconvergence, some of which is normal in all color monitors. I'm talking about entire areas, or perhaps even the whole picture, having undesired color. To be sure everything's set right, try turning the brightness down to about 1/3 normal. If the picture turns a different color, you need to set up the color balance and tracking. I make it a matter of course to do that on any hamfest monitor I fix.

This set of adjustments can take awhile, but it isn't hard. Set the black and white picture to low brightness (but not way, way down to where you can barely see it), and find the color controls on the back of the set. Often, they'll be on a PC board attached directly to the back of the CRT. Sometimes, though, the board is mounted behind the tube.

You should have six controls: three for screen (not the same thing as the screen control on the flyback), and three for drive. There are three of each, of course, because each of the three guns (red, green and blue) needs its own set. Sometimes, the screen controls will be labeled "bias." and/or the drive controls will be labeled "highlight," or something similar. It should be apparent which are which, anyway. If you only find two of each, that means one color, usually green, has its values fixed, and you must adjust the other two relative to it. If you find a total of three, chances are your monitor has only drive controls, with fixed screen values. It is easier to adjust such sets.

because you aren't setting the screen controls, but they don't produce color as accurate as monitors with all the controls. I've only seen that configuration once or twice.

The screen controls set the amount of each color you will get in low-brightness areas of the picture. You must adjust them first, because they affect the brighter areas too, at least to some degree. Since your monitor was at one time in good alignment, don't try messing with all three controls; just adjust the one that seems prominent. If you have too much red, for instance, turn the red screen control down until it goes away. If it's already all the way down, you will have to turn the others up to balance with the amount of red. Your goal is a uniformly gray picture.

Once you get it, turn the brightness up to normal and adjust the drive controls for good white in the picture's highlights. Do it the same way, turning only the one that's prominent, and then touching everything up for least coloration. Theoretically, you're all finished. In practice, though, you will find you have to go back and do the procedure several times, because the two sets of controls interact. No matter how hard you try, though, you may find it's impossible to get it exactly right. As long as the picture looks good at normal brightness levels, don't worry about it. But, if you can't get it even close, your CRT may be weak. Sometimes you can get a TV shop to "rejuvenate" a CRT, using a special device, but it doesn't always make too much difference, and, now and then, it can destroy the tube.

Once you've done all this, go back and touch up the focus control. Now, set your computer for a color picture and stand back—you should have a gorgeous image.

And that's the story of, that's the glory of, setting up a color monitor! I'm typing this article on a 14" SVGA monitor hooked to my Mac. I got the set for $5 (it was dead, of course), and it looks as good as any I've ever seen in a store, and better than a lot of them. This stuff really works.

Until next time, 73 from KB1UM.

Three-Element Direct Connect Beam for 2m

A Tiny 2+1.

Edward Oros AC3L
2629 Sapling Drive
Allison Park PA 15101

If the concept of my direct connect antenna ("1, 2, 4 — A Geometric Progression That You'll Love" from the September 1995 issue of *Radio Fun*) caught your attention, you might also be interested in a three-element version of the antenna. (The "Tiny 2" utilizes two elements: the driven element is 1 foot, 7 inches for each side, and the director is 2 feet, 9-1/4 inches.)

As with any standard three-element design, this three-element direct connect antenna utilizes a reflector and a director to achieve gain. As in the case of the "Tiny 2" the front-to-back was sacrificed in order to squeeze as much gain as possible for the antenna. I managed to obtain 6.52 dB over a dipole in free space while still retaining a direct connect antenna.

Right up front you might ask, "Why build this antenna rather than some other design?" The first reason is the very fact that it *is* a direct connect antenna. The design allows you to hook your cable directly to the antenna without the time-consuming process of matching, yet the SWR is just 1.18 to 1. The 6-1/2 dB gain is, of course, a nice bonus. Another appealing feature of this design is the element diameter. Each of the elements is made from 1-inch diameter aluminum tubing. I like the fact that you don't have to play around sliding elements in and out trying to get to the proper lengths. You simply cut each to the lengths shown in Fig. 1 and position the elements on the boom. It is also easy to find 1-inch furniture tips at local hardware stores (they give the antenna a slick professional look).

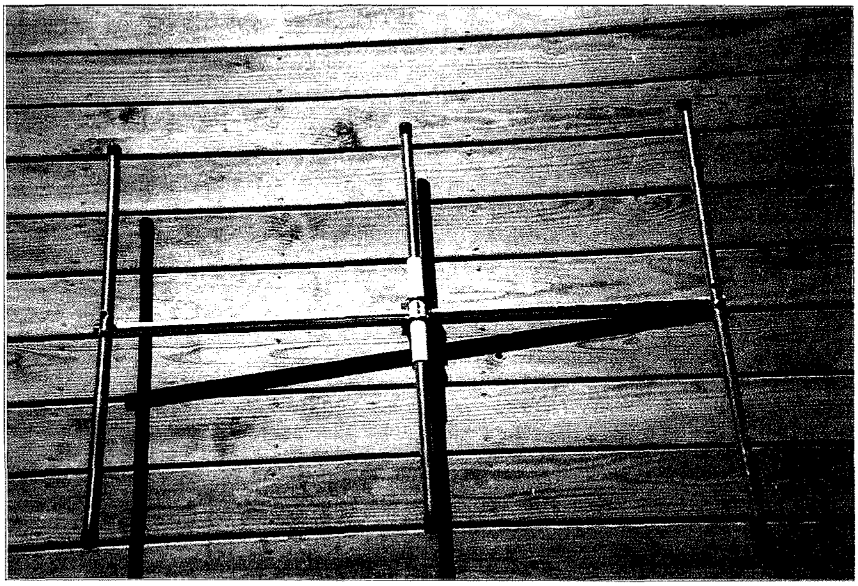

Photo A. It should look like this when you're done.

"Quick, slick — a good pick for first-timers!"

Construction Notes and Hints

You will need a boom length of about 4' 2" even though the distance between the reflector and the director is only 4 feet. The extra space is needed to allow for the use of mounting brackets to hold each element to the boom. As far as connecting the elements goes, any of the popular mounting techniques can be used to attach the elements; you can even use the double bracket clamp method from the "Tiny 2" design if you wish. Center each of the elements by using the center point column illustrated in the sidebar. When mounting the driven element, remember that it is split at the center and must be insulated from the boom; you can use PVC pipe to accomplish this. It helps to insulate the elements, and supports them at the same time.

To Build or Not To Build

There are so many antenna designs out there that it may be difficult to decide which one is worth your effort. The simplicity of this three-element direct connect antenna makes it perfect for clubs and organizations looking for a "first time" antenna project. The proper location for connecting the

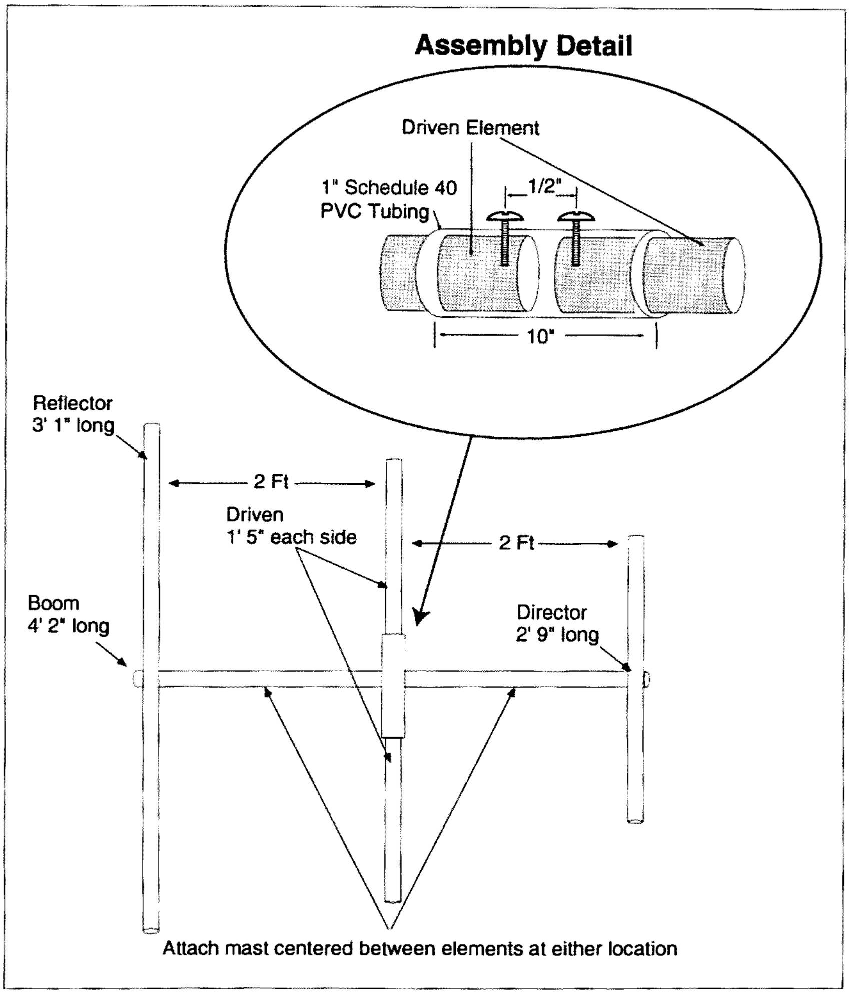

Fig. 1. Construction details.

mast is exactly center, either between the driven element and the director, or between the driven element and the reflector. Connecting a metallic mast any closer to the elements will detune the antenna causing a higher SWR. ■

NEVER SAY DIE

Continued from page 39

will expect to see you there with your entrepreneurial antenna raised. If you come across any newspaper articles you think I ought to know about, clip 'em and share them. Don't worry that someone else may have sent it too. I'd rather have five than none. I want to know what is going on in almost any new technology. I want to know about any really good ideas for helping to solve our social problems. And our health, education, and so on.

But you should be learning all you can about these things too. Long after you've forgotten a "Roseanne" episode or a ball game, your new knowledge will be with you.

My apologies. I'm probably boring you. I'm stupidly trying to change human nature. The optimist in me keeps making me forget how resistant almost everyone is to change. That's the reason I stopped doing Dianetic therapy back in 1951. I read about it in the book when it came out. It made sense, so I tried it. It worked beyond my highest expectations, so I quit my job, went to the Dianetic Research Foundation and got to be really good at it. And I cleaned out all of

HAM TO HAM

Your Input Welcome Here

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

In the December 1995 "Ham To Ham" column I wrote about using an IR detector diode across the mike input of a high gain audio amplifier in order to test the remote's operation — at least to determine if it's outputting pulses. Klaus Wolter N8NXF of Ann Arbor MI notes that another way to "view" IR LEDs is via a CCD television camera. Apparently, some CCD cameras have enough response in the infrared region to "see" these remotes pulsing when aimed at the camera's lens. Vidicon cameras probably won't. On the other hand, F.A. Bartlett W6OWP, and Erich Kern wrote in saying that all you really need to do is to hold the IR remote next to the tuning section of any AM broadcast receiver to "hear" the pulses. They're right, because these hand-held IR remotes put out a fair amount of digital pollution, they'll come over an AM receiver very nicely, proving that there is indeed room for too much engineering sometimes! For testing the operation of IR headphones and microphones, the IR detector/audio amp idea that I proposed is still perhaps the best way, but there are always other alternatives...which brings me to the purpose of this column; to provide a forum for your ideas, even if they may be "different." A good initial response has been received, but I still need many more tips, ideas, suggestions and better ways of doing things from all *73* readers. Don't worry about your writing skills, just include as much detail as you can and I'll put it together in the style of the column. Let's hear from you!

This month we begin a series of tips offered by Richard Measures AG6K, of Somis CA. Rich has done a tremendous amount of research into VHF parasitic oscillation suppression in amateur HF linear amplifiers, as well as fathering many practical servicing tips for some of the current amateur transceivers and accessories. With Rich's permission, I've condensed some of his best suggestions into the column's format, and over the coming months I'll include one of his tips in each column...be sure to watch for them.

One inoperative meter cure

From Richard Measures AG6K: An inoperative meter may not necessarily be bad, just in need of an overhaul. With time, humidity and the natural corrosive effects of the atmosphere, the meter used in the Heath SB-220 linear amplifier can appear to be unusable. But as in other areas of life, appearances can often be deceptive. The meter Heath used in the SB-220 is not unlike the meters used in many other pieces of ham gear, so the techniques I'll explain here aren't just for SB-220 owners by any means. Here's the reason: many meters are assembled using different types of metals for the various meter parts. These parts, which are then expected to conduct current to the meter's armature, are fastened together using machine screws at the joining points that act as the electrical conductors within the meter. As previously mentioned, time, and the effects of humidity and air pollutants, can result in electrolysis occurring at the junctions of these dissimilar metals — a perfectly natural phenomenon — but definitely not desirable within our meters! The increased resistance at these junctions can cause an intermittent or open connection at various points between its rear terminal and the meter's movement.

The problem can often be solved simply by prying off the plastic meter face cover, *carefully* removing the scale—usually held in place with two tiny screws—and then applying small dabs of conductive paint (such as GC Electronics Silver Print) to all of the dissimilar junctions that carry current to the meter's armature winding. The conductive paint can be applied with a straightened-out paper clip; it can also be thinned with ordinary acetone to facilitate penetration into any narrow areas between parts. However, be careful not to get it on anything that shouldn't conduct electricity! Also, it should be allowed to dry *thoroughly* before any reassembly takes place, since the fumes could cause problems of their own.

Be very careful when working inside one these little meters, a wrong slip could spell the end for it, but at least give it a try...chances are better than even that you'll be successful, which is a whole lot better than if you'd done nothing at all.

The silver conductive paint that Rich refers to can often be obtained from local electronic suppliers or by mail order from the larger supply houses. MCM Electronics (1-800-543-4330) stocks their catalog #21-1555 Silver Conductive Pen.

An "automatic" antenna disconnect suggestion

If you take advantage of a "master" station-power on/off switch, as do I, to disconnect all power from your station equipment to prevent "unauthorized little fingers" from turning on your ham gear, then here's an extension of that protection for your antenna circuit as well.

Disconnecting your outdoor antenna from your transceiver, when the equipment is not in use, is always a worthwhile safety precaution, in the event of a nearby lightning strike or other static buildup that might occur. It can be made "automatic" very easily, by simply installing a coil-actuated antenna relay in the path between your antenna's transmission line and the station transceiver. Coil-actuated antenna relays used to be quite common in the days of separate transmitter/receiver combinations, to switch the antenna between those two units, before the current trend of transceivers with built-in T/R (transmit/receive) switching. I've often seen them at hamfests, amid other "ancient gear," and at very reasonable prices. If the T/R relay has a 120 volt AC coil, you're all set, just put a cord and AC plug on it, and plug it into your "master" AC strip. If it has a 12 volt DC coil—as might have been used in a mobile set-up—then wire it to your station 12 volt DC power supply's output, as long as the 12 volt power supply is switched off with the "master" switch.

Make sure that the relay's contacts will handle your normal output power—most will—and clean the contacts with a thin strip of 3" x 5" index-file-card material, soaked in contact cleaner, via the relay's contact access port. The contact access port is usually covered with a removable cover plug, or in some cases, the whole cover of the relay itself may have to be removed. It's not usually a very difficult job. Don't file the contacts unless you've had lots of experience with relay maintenance though; they're usually silver (plated or solid) and you can do more harm than good by filing them—use only a paper file card, not a file! A special diamond-dust relay burnishing tool, with proper instructions, is normally used if filing is absolutely necessary.

Now cable the relay in series with your incoming antenna coax, so that your antenna system will be connected to your transceiver's output when the relay is "pulled up." Install a "shorted" coax connector into the leftover fitting, so that the antenna's transmission line is shorted when relay is relaxed—when the station AC power is "off." Finally, ground the body of the relay to a reliable earth-ground to "bleed" any static buildup safely away to the earth.

With your transceiver's antenna lead automatically disconnected, and the antenna itself shorted, you can sleep a bit more comfortably when spring thunderstorms approach. This won't completely protect your equipment from a direct hit (very little will) but it does help to protect your investment from nearby lightning hits and static build-up damage.

Dig out your mobile vertical!

From William Thim N1QVQ, of Broad Brook CT: A winterwise tip that may still have application this season for some. While you're in the process of cleaning that snow and ice off your car windows, don't forget to dig out your mobile antenna! A buildup of snow and ice around the base of your VHF or UHF mobile whip antenna can significantly raise your SWR, even to the point of forcing your transmitter to cut back on its power output. Check it with a good SWR bridge and

you'll see what I mean. Two or three inches of snow built up around the lower active portion of the antenna will often result in a noticeable SWR change.

Bill brings up a good point, though the bottom part of a 1/4-wave vertical is the high-current, low-impedance end of the antenna. Depending upon the amount of snow and ice and the operating frequency involved, the tuning of the antenna — and its losses — can be altered quite a bit. It's something we may not always think of when we're not hitting the repeater quite as well as we used to!

All-purpose probing tool from the Far East

From Herb Foster AD4UA of Melbourne FL comes this suggestion: Whenever I'm working on a piece of electronic equipment, I like to have an insulated tool in one hand to point, probe or gently tap a component or connection that might be suspect. This one is effective and, best of all, free!

Most Chinese restaurants give away bamboo chopsticks to their customers, to kind of get you into the spirit of eating out oriental style. So the next time you have the urge to take in one of these restaurants, save the chopsticks for your workbench tool inventory. When you get back home, wash them and carve one end of each into a point, a flat-blade screwdriver or even a hex-type of core-adjusting tool, and keep them handy on your bench. You can use them to poke around a crowded circuit board without fear of shorting anything out, or even use one to prop something open, if your transceiver is built into "layers" as so many are these days. And if your neck starts to itch, you can even use it to reach behind and scratch!

All you need do to obtain a supply of your own is to develop a liking for Chinese food, then take the wife and kids out for dinner. Even if you don't care to try manipulating your meal with the chopsticks, that's okay too, they'll loan you a fork and still let you keep the chopsticks...and you can't beat the fortune cookie at meal's end either!

Good idea, Herb. Bamboo keeps its shape better than many other woods, so whatever type of tip you might put on the end, chances are it will last longer than pine or other soft wood. By the way, if the fortune cookie says something like: "Avoid anything electronic today," better listen to it—you never know!

Airing taped telephone ham bulletins

From Mike Schroeder NØALJ of Rogers AR, several ideas for those of you who might be contemplating handling the airing of telephone-line originated amateur radio bulletin services for use on your local repeater's net-night get-together: I've been assigned to air the bulletin services—such as RAIN and Newsline—on our Monday night repeater net on 146.76 MHz, and I felt that I needed the best quality telephone audio possible, plus an easy-to-install record/playback system. Instead of a simple telephone inductive pick-up coil, the Radio Shack™ #43-228 does a much better job, has a built-in speaker, so it allows me to monitor what's being laid down on tape. I also use a multi-memory phone to make dialing easier and so that I can program in alternate numbers, just in case the ones I normally use are busy.

Another interesting method I've found to make quality recordings is to dial up the service you want to record on a cordless phone, then use a scanner to pick-up the radio frequency of your phone, and make a recording from the external speaker jack of that scanner.

As far as playback of the tapes over-the-air on net-night, if you want something simple, you might try an inductive pick-up coil backwards—such as the RS #44-533—if you have a dynamic or magnetic type of mike on your 2-meter transceiver. In other words, feed the tape machine's earphone/speaker audio output into the inductive pickup, and place the coil over your mike. This won't work on the new electret-condenser type microphones, but in that case, the easy to build interface box shown in Fig. 1 can be used.

Using an inexpensive digital timer (such as the Radio Shack

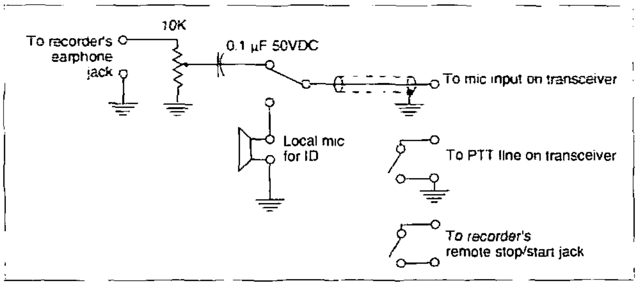

Fig. 1. NØALJ's Net Bulletin recorder controller.

#63-884) that's started when the tape is started will give you an elapsed time indicator, so that station IDs can be inserted at the proper times. The tape can be paused for the ID by simply having an SPST toggle switch on a cord, plugged into the tape machine's remote stop/start jack. If fact, all of these functions can be integrated into the one central control box (see Fig. 1) - recorder interface with its mike/tape switch, remote tape stop/start switch, transmitter PTT switch and a small digital timer—all equipped with the correct plugs to mate with your specific equipment. On net night then, it's almost an automatic few-second setup to get things going correctly, instead of a Murphy-prone chore!

Good tips, Mike. Building everything inside a metal box and using shielded cabling will help to reduce the possibility of RFI problems during the on-the-air phase of the operation. If you still have problems, try putting small ferrite beads on all the input/output leads, and/or .001 µF disc capacitors from the offending lead to ground. At 2 meters, sometimes a lead will inadvertently end up being either 19" or 38" long, acting as a resonant pick-up antenna for your own signal! Check for that too.

For your files

From Joel Masur AA5YA of DeLand FL: a few good suggestions for working aluminum sheet stock. What follows is an idea that you might want to try if you've ever had difficulty "squaring up" aluminum sheet stock for panels, etc. Try to locate an old time lead body file, mine is a New Britain #285; an auto parts store or older auto body shop might be a good place to start. Mount it on a husky wooden handle, so that it resembles a flattened wooden block plane. The half-moon shaped teeth in a file like this will eat-away at the soft aluminum very nicely, without the normal tooth-clog problem we're all familiar with in finer-tooth files.

Additionally, you might try Forstner wooden bit and power auger files for getting into the corners of the square or rectangular cutouts needed for snap-in switches, etc. The ones I have are 7" long, 1/8" thick and 7/16" at the widest part. They're shaped something like a diamond that's been stretched-out to the 7" length but with a 1/4" wide by 1-1/2" long connection strip. One end of it has teeth on the flat side and none on the edges; the other end is exactly opposite...no teeth on the flat side but teeth on the edges.

Now that you have the tools, what about the stock? Free is always nice, and here's an approach you might want to try. Make friends with the public works department foreman in your town and see if he has any salvaged road signs that he'd just as soon get rid of. They can make great electronics panels if they're not badly damaged. Leave any decals on until you've cut and finished the material for the project you're working on for protection of the under-finish.

Octagonal "stop" signs make nice 2 meter ground planes for a mag-mount antenna, providing they're made of steel. Other steel traffic control signs can be used for the same purpose if they're sized about right (roughly 40" by 40").

If the public works foreman has any outdated aluminum traffic control counter boxes taking up space, latch onto them; they're the boxes you'll sometimes see placed at the side of the road, chained to a tree, with a long rubber tube coming out of them and

onto the roadway. They count the number of cars using a particular road over a period of a few days, but the discarded ones also make great boxes for outdoor tuning units, power supplies, or even an entire mountain-topping QRP station! The air hose hole can serve as an input/output access. Just be sure to go through the right channels when helping them to get rid of their obsolete signs and boxes; you don't want to be operating portable from the police department's holding cell!

If the auto body shops you check with don't have the files that Joel is referring to, ask them where they purchase their supplies and try directly. You might also check with the W.W. Grainger outlet nearest you, as well as any other contractors' supply houses in your area.

Quick tip for testing transistors

From Peter Albright AA2AD of Lakewood NY: This suggestion for quickly testing out-of-circuit transistors. Here's an easy method of using a multimeter's "ohms" scale to reliably test transistors. The very few minor limitations are as follows:

1. It works best with an analog (needle style), rather than a digital meter.

2. It should only be relied upon when the transistor has been removed from circuit.

3. The test works on bipolar transistors only, not on FETs, SCRs, etc.

4. It doesn't yield any information on a transistor's gain or "beta."

The limitations, in my opinion, are more than offset by these advantages:

1. The test is fast and requires no specialized equipment.

2. You will get no false "defective" results.

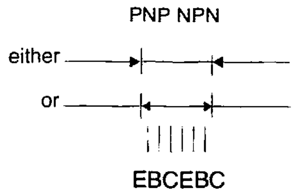
3. The only false "good" result might be from a thermally-sensitive transistor, i.e. if the transistor only shows a defect under the stress of heat during actual operation.

4. It can often be used as a first step in identifying lead configuration.

Here's the theory: There are two types of semiconductor material, "P" type and "N" type. A junction diode, such as a silicon power diode, consists of one layer of "P" material mated against one layer of "N" material, and this junction conducts current in one direction only.

Bipolar transistors, on the other hand, always consist of three alternating layers of these three materials — either "PNP" or "NPN" — with a wire connected to each of those three layers. To an ohmmeter, which has only two test leads, the transistor looks like two diodes, either back-to-back, or face-to-face. This concept alone takes a lot of the mystery out of transistors.

Regardless of which type of transistor is being tested, the wire to the center layer is the base, while the two outside layers are the emitter and the collector. So the configurations, when drawn as diodes, are:



In practice, it's really easy to test a diode with an ohmmeter. Set the meter to the R times 1K range. Measure the resistance, first in one direction and then in the other, by reversing the ohmmeter's test probes. Silicon diodes will measure virtually infinite resistance when the positive probe is connected to the diode's cathode (usually marked by a band). Conversely, they'll measure some continuity when the positive probe is connected to the anode. Note that not all multimeters apply a positive voltage to the red meter lead; you'll have to test your own meter with a known good diode first, then mark the meter as to which test lead is actually outputting a positive voltage. It need only be done once. Germanium and selenium diodes on the other hand, which are point-contact diodes, rather than junction diodes, may show some continuity in both directions, but the amount of continuity in one direction, will always be much higher than the other, if the device is good.

If you're still with me, you've probably already figured out how to test a transistor with an ohmmeter, thinking of it in terms of two diodes. Here's the procedure, in step-by-step format:

1. ALWAYS turn the equipment off, unplug it or remove the battery, and discharge any filter capacitors — usually identified as the physically larger capacitors.

2. Remove the suspected bad transistor by carefully unsoldering it from the circuit.

3. Set your ohmmeter to the R times 1K scale or higher. This limits the testing current, protecting the transistor from damage. Don't use the very low ranges on your meter for these tests.

4. Connect either lead of your ohmmeter to what you believe to be the base of the transistor.

5. Measure the resistance to each of the other two leads. The reading should be the same for both leads: either nearly infinite (open) or finite (some continuity).

6. Now switch probes: that is, connect the other probe tip to the base.

7. With the probes now reversed, measure the resistance to each of the leads once again.

The reading should again be the same for both leads.

a.) If your result the first time around was "infinite," then you should now see some continuity between base and emitter as well as between base and collector.

b.) If your first round results showed "continuity," then your measurement now should be nearly "infinite" resistance (open) to both emitter and collector.

8. If you get some result other than these, then assume that the transistor is defective.

Notes:

a.) As with germanium diodes, germanium transistors may show some continuity in both directions, but there will be a distinct difference in the resistance when you reverse the probes. You probably won't find many germanium transistors in equipment less than twenty years old, but you will find germanium diodes in more recent gear.

b.) If the transistor is bolted to a metal heat sink and has only two leads coming out of it, then the bolt tab or threaded stud will be the third connection. Bolt tabs and studs are always the collector.

c.) If you don't know the lead configuration of a device, you can use this technique, along with trial and error, to at least identify the base lead, provided the device isn't defective.

If you REALLY understand this technique, it can save a lot of time and trouble, as well as taking some of the mystery out of transistors and solid-state electronic troubleshooting in general.

Peter's suggestion is a good one to remember: it's a good "quick test." It might pay to clip this out and post it near your workbench, so that it's handy the next time you need it. It would also pay to practice on a few good transistors, now, just to get a "feel" for what he's saying and to overcome any reluctance you might feel toward solid-state troubleshooting. Hands-on learning is always worthwhile: after all, you can't do much harm...and it's good hand-to-eye coordination practice!

A Simple One-Hour
Continued from page 40

The few components can be mounted on a terminal strip. R1 is best attached to either the rear of the meter case or the interior of the enclosure, using epoxy, superglue or hot glue.

Calibration

Look at your meter scale. With luck there will be four main divisions. If not, carefully take the meter apart and divide the meter scale into four equal, 10-volt divisions, using a fine tip felt pen. Mark these points 90, 100, 110, 120, 130, starting at the zero end of the scale as follows: The space between 90 and 100 is one division; between 100 and 110 is division two; between 110 and 120 is the third division; and the final division is between 120 and 130 at full scale. Reassemble the meter and mount it in its enclosure.

If you are unfamiliar with disassembling meters, please see my article, "Use Those Surplus Meters," *73 Amateur Radio Today*, January 1992, page 42.

With your meter scale properly calibrated and all parts mounted in the enclosure, adjust R1 to maximum resistance. Using an accurate AC meter—a digital multimeter is preferred for accuracy, but a V-O-M can be used—measure the AC voltage at the nearest outlet, and note this value.

Plug in the Line Voltage Monitor. Being very careful not to touch any points carrying voltage, adjust R1 so the meter indicates the same voltage you measured previously. This completes calibration.

Operation is automatic. When this instrument is plugged into a live 117 VAC outlet it will continually monitor the level of voltage supplied by the power company.

Notes

Be sure the meter you use has a moving coil (D'Arsonval) movement. Do not use an iron vane meter. If you can't tell the difference at a glance, a good rule of thumb is: If it looks expensive, it probably is a D'Arsonval meter. If it is round or square and has a cheap-looking black painted metal case held together with bent metal tabs, it is probably an iron vane meter.

There are similar-looking line voltage meters commercially available costing about $20. Some of these appear to use an iron vane meter. You can build a better monitor for a lot less money.

A major disadvantage of using an iron vane meter to which a voltage is applied continuously is that they lose accuracy as the movement becomes magnetized. You'll find that, if you unplug one after a year in use, the needle will not return to the left end of the scale. Instead, it will indicate some level of voltage even though none is being applied.

An excellent and inexpensive source of surplus name-brand meters with D'Arsonval movements is Fair Radio Sales, Box 1105, Lima, OH 45802. A selection of five meters (their choice, not yours), Catalog No. 47-84, costs $10. Mostly basic 0-1-mA movements will be in each selection. Usually there will be one, possibly two meters with 100-µA movements. Some may have internal shunts, multiplier resistors, or rectifiers, but these are easy to eliminate, leaving you with the desired basic meter movement. This gets you your meter for only $2, and you still have four more nice meters for future projects!

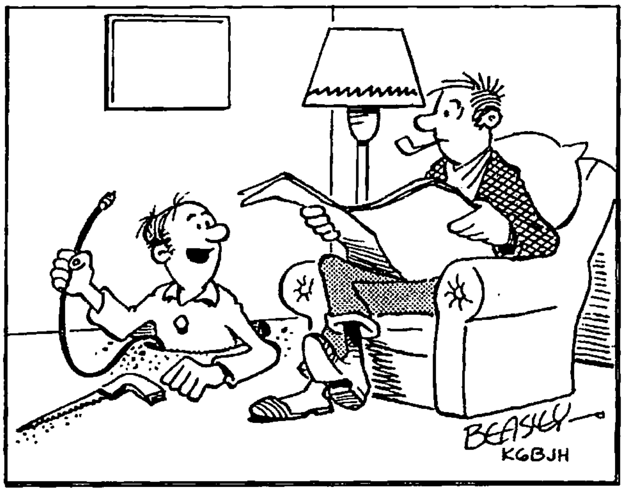
Calling Young Hams!

Carole Perry WB2MGP is looking for youngsters under the age of 18 who are enthusiastic about amateur radio to contact her about appearing at the DAYTON 96 HAMVENTION this year. Kids should have good speaking skills and be at ease in front of an audience.

Please write or phone at PO Box 131646, Staten Island NY 10313-0006; (718) 983-1416 **ASAP**. Have some fun, network with other hams, and wouldn't this look good on your college applicationss?



***Toon 2:** Hi, I'm the ham from downstairs—mind if I run my coax through here to the roof?*

A Little Hank of Wire

One of the problems in getting on the air, especially if you are short of cash, is the little matter of the antenna. One can spend anywhere from $29.95 to $5995.00 for an HF antenna for the ham bands, especially if one wants multi-band operation. In my early years of hamming I was perpetually broke, so learned first hand how to do things on the cheap. A couple hundred feet of wire and coaxial cable is not terribly expensive, but can make a dandy antenna.

Most of us are familiar with the half wavelength dipole, but it isn't the be-all and end-all of HF wire antennas. One of my favorites, and one of the earliest antennas that I used, was the Windom. The first Windom I saw was used by my mentor, the late Mac Parker W4II, although he wasn't enamored of it. We also had a Windom antenna on the roof of the Industrial Arts building of Washington-Lee High School (Arlington, VA) where K4BGA was the club call sign...and it worked a lot better.

The Windom antenna (Fig. 1) has been popular since the 1920s. Although Loren Windom is credited with the design, there were actually a number of contributors. Coworkers with Windom at the University of Illinois were John Byrne, E.F. Brooke, and W.L. Everett, and they are properly co-credited. The designation of Windom as the inventor was probably due to the publication of the idea (credited to Windom) in the July 1926 issue of *QST*. Additional (later) contributions were rendered by G2BI and GM11AA (Jim MacIntosh). We will continue the tradition of crediting Loren Windom, with the understanding that others also contributed to this antenna design.

The Windom is a roughly half-wavelength antenna that will also work on even harmonics of the fundamental frequency. The basic premise is that the antenna radiation resistance varies from about 50W, to about 5,000 W, depending upon the selected feedpoint. When fed in the exact center, a current node, the feedpoint impedance will be 50 W; similarly, end-feeding the antenna finds a feedpoint impedance of about 5,000 W. In Fig. 1 the feedpoint is tapped away from the center at a point that is about one-third (0.37L) the way from one end, at a point where the impedance is about 600 W.

The feedline for the basic Windom of Fig. 1 is an insulated length of wire. Of course, the size of the wire depends on the power level, but I suspect that #14 insulated stranded wire will do for most people who run less than 200 watts of power. Indeed, I wouldn't like to use a Windom at high power levels because of the "RF in the shack" problem.

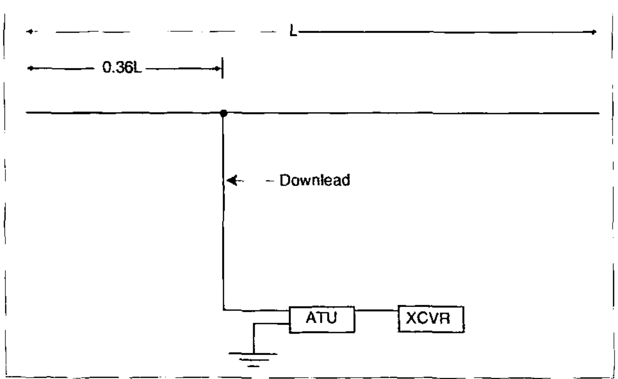

Fig. 1. The basic Windom antenna.

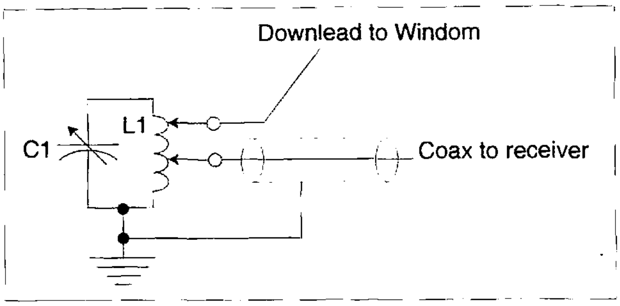

Fig. 2. Antenna tuning unit for Windom.

The Windom antenna works well....but with some serious caveats. For example, the antenna has a tendency to put "RF in the shack" because it is voltage-fed. Second, there is some radiation loss from the feedline. Finally, the antenna works poorly on add harmonics of the fundamental frequency.

The antenna tuning unit can be either a parallel resonant, link-coupled, LC tank circuit (see Fig. 2); or a reversed pi-network. In the case of the Windom, the pi-network is turned around backwards from the usual configuration: C1 is at the low impedance end of the network, so it is larger than C2. Design a pi-network to match 50 = on the transmitter end, and 600 = on the antenna end.

Note that a good ground should be used with this antenna (note the ground connection at the output of the antenna tuning unit). This means (for most people) an eight-foot ground rod, or a system of radials.

A reasonable compromise Windom, that reduces feedline radiation losses, is shown in Fig. 3. In this antenna a 4:1 balun transformer is placed at the feedpoint, and this in turn is connected to 75 W coaxial transmission line to the transmitter. A transmatch, or similar antenna tuner, is then connected between the transmitter and the transmission line.

An Old Myth Revived?

There are a number of myths that are widely held among radio communications hobbyists...and amateur radio is no less infested with some of these myths than others (CB, for example). Twenty-five years ago I worked in a CB shop in Virginia, and we kept hearing one old saw over and over again: you can cut your coax to reduce the VSWR to 1 (actually, they meant "1:1" but routinely called it 1). Hordes of CBers have cut the coax and watched the VSWR reduce to 1:1, so they cannot be talked out of the error. What actually happens in that case is a measurement difficulty that makes it appear to be true.

Of course, Hams are superior to CBers so don't believe that error, right? I'd like to think so; but having been in both the CB and the amateur worlds, and "Elmered" more than a few CBers studying for amateur licenses, I have to admit that at least as many amateurs believe the "cut-the-coax" error as CBers (sorry, fellows, but that's my observation). Recently, a couple questions on this topic arrived in my E-mail box (carrjj@aol.com).

The only really proper way to reduce the VSWR to 1:1, in my opinion, is to tune the antenna to resonance. For a center-fed half wavelength dipole, or a bottom-fed quarter wavelength vertical, the proper way to resonate the antenna is to adjust its length to the correct point. The formulas in the books and magazines only give approximate lengths...the real length is found from experimentation on the particular antenna after it is installed. Even commercial antennas are adjusted this way. On certain CB mobile antennas, for example, this trick is done by raising (or lowering) the radiator while watching the VSWR meter. On amateur antennas similar tuning procedures are used.

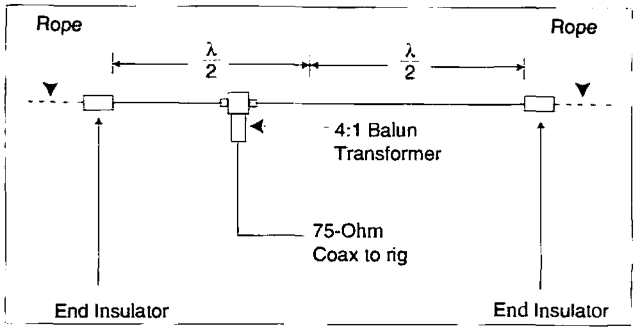

Fig. 3. 4:1 Balun

Another ploy used by amateurs (including myself) is to connect an antenna matching unit (tuner) at the output of the transmitter. For my Kenwood TS-430, I use either a Heath SA-2060A or an MFJ Differential Tuner to "tune-out" the VSWR presented by my Hustler 4BTV and 75 feet of coax. But I don't even pretend to be tuning the antenna. The TS-430 is a solid-state rig, and the finals are, therefore, not terribly tolerant of VSWR, and will shut down with a high VSWR. The purpose of the antenna tuner is to reduce the VSWR seen by the transmitter...and to heck with the actual antenna mismatch on the roof. The tuner also serves to reduce harmonics further, thereby helping to prevent TVI. The best form of antenna tuner is one that both reduces the VSWR (for the benefit of the transmitter), and also resonates to the antenna frequency, preventing harmonics from getting out (a dirty little secret is that many "line flattener" ATUs are actually variable high-pass filters, and must be used with a low-pass filter ahead of them if spurious signals are to be kept at home.

Clarification

I received a number of queries in my America On-line mail box about the "Quick 'n' Dirty Twin-Lead Antenna" discussed in this column a couple months ago. I still get feedback on that antenna, and have made at least one correction on it, but the questions continue, so here goes again. The two conductors at the far end of the twin-lead are shorted together. If you check the continuity of this antenna with an ohmmeter at the feedpoint end you will read a short circuit (or only a few ohms of DC resistance, depending on length). The antenna is not left open, or will not work.

Another requirement not made all that clear in my article is the fact that this is basically a form of Marconi antenna, so needs a very good ground to work effectively. As mentioned above, this means that you should get an eight-foot copper-clad steel ground rod, or lay in a system of radials. I should have mentioned that originally, but somehow it slipped my mind until a couple of experienced, sharp-eyed readers spotted the error. Sorry.

Connections...

I welcome your comments and questions, as well as ideas for this column. My snail mail address is P.O. Box 1099, Falls Church VA 22041, and my Internet E-mail address is carrjj@aol.com. 73

QRP

Number 62 on your Feedback card

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

Been there? Done it? Try life in the QRP lane.

There seems to be an increase in hams (re)discovering low power operation. Called QRP, it's an interesting way to get back into ham radio after you've done it all!

Several years ago, we looked at some of the frequently asked questions about QRP. There seemed to be a pattern, so I recently went through piles of letters and picked out some others. Here is an updated version with even more frequently asked questions answered—in no particular order. Enjoy!

What are the most popular QRP bands?

There really is no one band more popular than others. You'll find QRP operation from DC to light, but most QRP activity may be found on the 40-meter band around 7.040 MHz. Also check 7.035 MHz as well as 7.060 MHz for QRP operators. You'll find many of the European stations lurking around 7.030 to 7.035 MHz. Start with 28.060 (although it's not carved in stone) as the 10-meter QRP calling frequency. The 30-meter band is a QRPers delight! Try 10.106 and up for low power signals. There're lots of HF packet on the very high end of 30 meters. If you have a QRP rig that will operate SSB, give HF packet a try.

Let's not forget about the 20 meter band either. This is by far the most popular ham band when it comes to working DX. Low power operation used to be located around 14.060 MHz, but alas, other forms of digital signals have been moving down, overtaking the QRP calling frequency. Check the entire band for QRP operators; they're everywhere on 20. Fifteen meters is also quite popular, but with the current lack of sun spots, activity is a bit sparse. Always check the band, however, at or near 21.040-21.065 for QRP operators.

"I'm not 'into' CW. Can I still operate QRP?"

CW is by far the most popular mode of use for QRP operation, partly because CW transmitters are easier to build than SSB rigs. With CW, you get more bang for the watt too. But QRP is not only CW; it's any mode you want to use, be it FM or SSTV. Remember QRP means low power—not CW only.

There's been an increase in activity on 6 meters due to the influx of multiband mobile rigs. Don't let it throw you. A inexpensive 6 meter transverter is now available from TenTec at a very reasonable price.

The #1 absolute *must* on 6m is a good antenna. A wire between two bushes just won't do. A chopped up and converted CB beam antenna makes an ideal and inexpensive beam for six meters.

"Do I need to change rigs or equipment to operate QRP?"

Of course not! Most of today's rigs can be easily turned down from a front panel control. You'll end up with low transmitter efficiency, but you won't have to spend a dime either. The Index Lab rig covers all ham bands, plus a general coverage receiver. The rig operates on SSB and CW; it will set you back $700.

"How about antennas? All I have is a simple dipole."

No matter what the power level in an amateur radio station, the better the antenna, the better your signal will get out. Use a good grade of feedline and get the antenna as high as possible.

"I enjoy a good contest now and then. How can I compete with other stations if I run 2 watts?"

Most of the bigger contests such as the CQ World Wide DX contest, Sweepstakes and even Field Day have special low power sections. You only compete against others within the same power class.

"The bands are dead, as is my final; now what do I do?"

Surf the net! There are 700+ members on the Internet QRP-l group. To subscribe to the newsgroup do the following from your web browser or mailer: Send an E-mail to listserv@lehigh.edu in the body of the message type SUBSCRIBE QRP-L

Then follow with your name and call.

Yup! It's that time again!

The Dayton HamVention will be May 17-19 this year, so mark your calendars! The QRP ARCI will be hosting a weekend-long QRP session at the Day's Inn at the South Dayton Mall. Things begin Thursday and wind down Sunday afternoon. As usual, the QRP ARCI has several blocks of rooms reserved. If you want to stay with us, call Myron Koyle at (216) 477-5717 to reserve your room. If you were with us last year, and you filled out one of the yellow 1996 application forms, you're all set. However, if there should be a change in your plans, be sure to get in touch with Myron to update his files.

The QRP ARCI will also host several talks during the HamVention. Saturday night will be our awards banquet. There is always something to see or do at the hospitality suite before and after the banquet. Along with the QRP ARCI in Dayton will be the Michigan QRP club, the NorCal club, the G-QRP club and a boatful of others.

There are all kinds of things to do at Dayton for the QRP-challenged! Many of the companies that specialize in QRP equipment showcase their newest creations at Dayton. Dick GØBPS from Kanga always brings the cutest gizmos from G-land. So, if you want a whole weekend of QRP, then set aside a few days in May. Remember, the date has been changed! The Dayton HamVention is now the week ending May 19, 1996.

Bring your stories of the rarest DX—any time you're more than 25 miles from home, you're an expert! Bring a carrying pouch, so you can lug home your very own DX-100! Bring lots of money, for all those things you really don't need! And bring your wife; she'll keep you in line. Hope to see you there! 73

Continued from page 55

really good at it. And I cleaned out all of the crap in my mind that had been defeating me. That's when I started reading and learning. Not long after that I started my first entrepreneurial businesses and made my first million.

But what I found was that I had the key to helping anyone get rid of the mental baggage that was making them sick and keeping them from being successful. Only I also found that almost no one had any desire to change. I was able to help people get out of insane asylums and lead productive, happy lives. But most people in asylums fought change. So I said to hell with it and started manufacturing loudspeakers.

At these science conferences I meet lots of people with great ideas, but without the gumption to capitalize on them. Steve Jobs would have gone nowhere without Mike Markkula, who's the guy who really made Apple. If Jobs hadn't screwed things up many of us would be using Apple IIt computers zipping along at 250 MHz instead of IBM clones. Or even Macs. Unless you have a memory of my editorials you probably haven't heard of the 65816 and 65832 chips Wozniak wanted to use to update the IIc. And that was just the beginning.

Start reading some of the books I've been recommending. Start meeting me at some conferences. Hey, buy me a lunch! Or maybe, if that's too much trouble, get your hamfest chairman to bribe me to take off a couple days and give a talk so I can whip some life into the turkeys around you. I might be able to get them to lose some of that lard hanging over their belts and clouding their brains. I might get them to actually think. Maybe not. Can I get them to start reading? I keep asking you to let me know of any book "I'm crazy if I don't read." I don't want to hear about good books, interesting books, or fun books. I want to hear about truly great books...and don't forget the address of the publisher so I can get a review copy. You already know I'm thrifty (aka cheap). If you don't, then you haven't been enjoying my travel books. I suppose I should put all them together into one big book the way Michael Crichton did. Hey, I've got to add his "Travels" to my list of must-read books. I'd forgotten about it!

If I can fit it into my schedule I'll come and talk at any hamfest where you can get at least 300 people together. And then pay for me and Sherry to make the trip, plus help me sell some of my books and magazines? Get me there a day early and arrange for me to be on the local radio and TV news and interview shows to help build attendance for the hamfest. I talk about so many things that you'll have to buy a tape of my talk to remember everything. I usually get into health, longevity, how to make money, hamming, new technologies, education, and so on.

This is a hobby!

A whole sheaf of papers landed on my desk describing what appears to be a three year total waste of a whole lot of people's time and money battling over a Southern California repeater. The bottom line is that yes, we sure do have some remarkably stupid jerks with ham tickets and no practical way of getting rid of them. If only it were as easy

Above & Beyond

The Care and Feeding of a VHF-to-Microwave Enthusiast

C. L. Houghton WB6IGP
San Diego Microwave Group
6345 Badger Lake Ave
San Diego CA 92119

Who and what is the San Diego Microwave Group? Do you have a newsletter? Does your group charge membership dues? How many members interested in microwave do you have? How did you get started in microwave operations and how do you keep a group together? What is it like to start a group-interest forum based on microwave and related subjects? How do you manage to keep interest going in today's ever-changing world? What type of microwave equipment does your group use?

Well, these and a few other questions are the most often asked of the San Diego Microwave Group. First, ours is not the only group involved with microwave. There are many other groups, all of which promote microwave communications, interest in build-it-yourself, and operation on our VHF through microwave bands. The San Bernardino Microwave Society, the North Texas Microwave Society, and the Pack Rats in the Northeast are just a few.

All of these fine groups act in concert, and depend on amateurs' willingness to disseminate individual and group technical knowledge to other amateurs through newsletters and technical sessions. It is this spirit of cooperation and sharing that has promoted a new interest in microwave activity and a resurgence of home microwave construction projects. It is in this arena that I am able to explore my most rewarding amateur activities, home brewing or converting a surplus item to a usable device for our amateur microwave bands.

I'd like to describe the San Diego Microwave Group's position. We try to put our best efforts forward in methods and technologies for new microwave construction projects. Part of our goal is to explore new bands and populate them, and examine the different propagation effects on that band, be it microwave or laser technologies. Sometimes it seems that we expend a lot of effort to jump up to a new frequency. I assure you that it is difficult trying to locate new, usable pieces of microwave equipment. Quite possibly we do it for the "rush" we get locating and constructing these devices.

It might seem comical to some, but we enjoy the chase and construction aspects of this realm of frequencies. Our group has modified many different commercial satellite microwave devices, converting them for use on amateur bands. The components can be hard to locate, but once built into a usable system can provide a platform for state-of-the-art systems and testing different forms of propagation. It's kind of like operation in a new frontier where you can't just dash out to the store and buy the equipment. Almost all of the equipment required is home-constructed. The first axiom: You must have a very good relationship with your soldering iron, or at least be prepared to become attached to it.

If radio communication and operation is your thing, why go to remote hilltops and other locations when the same communication could be done easily on other, lower-frequency bands? This seems to be the biggest question presented to our respective microwave groups. See if this makes sense to you. You can *catch* fish with a net and be very successful, but if you enjoy *fishing*, you might want to try the cutting edge of the sport — fly-fishing. It might not be as successful as to quantity, but proficiency with your method means you make up the difference in personal satisfaction.

The pleasure gained from fly-fishing can be compared with the same feeling of accomplishment and success that has re-inspired and invigorated amateur radio construction. As for my personal microwave communications experience, it's like going back to my early years of excitement and enjoyment fabricating much simpler tube-type equipment scrounged from old (1960s) TV receivers, etc. Just as it was in the beginning (sounds like a fairy tale) the initial excitement of constructing a simple crystal radio in the 1950s is renewed through microwave construction in the 1990s.

The San Diego Microwave Group was formed by interested radio amateurs to promote and develop circuitry and equipment using microwave frequencies and various modes to communicate with other amateurs. We do not publish a newsletter or charge dues, although some day we might have a newsletter when we can get the energy off the workbench and onto the keyboard. Until that time, this column has been (and will continue to be) the sounding board for interesting new projects that have polished our abilities and operational skills. We have tried new methods of discovery and learned a lot in the school of hard knocks.

Hopefully we have smoothed out some different applications and equipment to improve our circuitry, making operation easier and more enjoyable. If I couldn't draw on the experience and resources of our group, using their excellent technical abilities, this column would be diminished. The constant sharing of initiative modifications, and technical upgrading of various microwave systems enables me to present them to you; it's what makes our group click.

Information is distributed to our group members via two methods: one is our monthly meeting on every third Monday at the home of N6IZW. It provides eyeball QSOs along with equipment adjustments and tests. Our meetings are informal gatherings around a table of new widgets to be described or tested at the beginning of the meeting. Later we adjourn to a group discussion.

The second way to keep our group together and distribute information is to have an informal roundtable on the 2 meter Palomar repeater at 9 PM every Monday evening except the 3rd Monday of each month. (The Palomar repeater is located in Southern California and operates on 146.73 MHz, 600 kHz down. It is located on Palomar Mountain near the Hale or Mt. Palomar 200 inch telescope.) Discussions on these Monday nights range the gauntlet from simple to very technical operations. The topics are usually left up to the individuals checking in to the net—questions or information on new equipment or apparatus to share.

That's the basic premise of the "nets" that our group and similar other groups of amateurs have started. The primary function of a "net" is to pull in interested amateurs from all aspects of the hobby to inform them on VHF and above related topics, and to pull them into our world if they are interested. As with any venture, be it business or otherwise, if you don't advertise you don't get exposure. Exposure—that's all it takes to set up your own Microwave Group.

The San Diego Microwave Group was started through the efforts of Red Truax W6BLK. Red was a long standing member in the San Bernardino Microwave Society and wanted to start a similar organization here in San Diego, because of the 80 or so miles separating eye-to-eye discussions, and the effort required to attend meetings in San Bernardino. In the very early days Red had some stationery printed with the SDMG's logo on it and had several plastic ID badges made with the same logo and our call signs. Kerry N6IZW and I were among the small original group.

The badges were a gift from Red for the SDMG's first members. I remember well going to swap meets with Kerry and making short distance Gunnplexer 10 GHz contacts from two different parking spots at a drive-in theater where the swap fest was held. The operation at the swap meet was our "net" and it assembled a large group of interested amateurs who did not know, at that time, how to contact others who had a similar

interest. The "net" or show-and-tell at the swap meets was very successful as we soon had about 20 interested amateurs, all with similar goals and construction interests, microwave. Wide band FM operation on 10 GHz was in full swing.

Red participated in many of these early contact sessions and attended many meetings, showing a great heart and compassion for construction, and diving into microwave circuitry. I'm grateful to Red, who nudged me into this field. Unfortunately, Red's health was not good and he became a silent key, but not before he saw the beginnings of our group flourish. He envisioned and urged us into this realm and we do not forget him. We still have the badges he presented to us in those early days to remind us of his influence.

Why did we select 10 GHz to function with as a primary frequency and not some lower frequency? Well, when your current equipment was up to 450 MHz, at that time the jump to 10 GHz was quite a leap. However it was not made without lots of thought. We envisioned that 1296 MHz was similar in operation to 450 MHz in practice. The equipment for 2304 MHz, 3456 MHz and 5760 MHz was hard to obtain; surplus Gunn oscillators were being dumped on the market for 10 GHz. We just took advantage of the availability of the 10 GHz Gunn Burglar alarms and garage door openers that were starting to appear on the swap meet circuit in large numbers. We used the inexpensive materials and developed it into a wide band FM transceiver operating full duplex.

Power output was in the 10 milliwatt range, frequency was a little drifty and difficult to set. Waveguide absorption wavemeters allowed frequency to be set on a field day hilltop to ± 3 MHz accuracy. Sure it was a fishing expedition, but an enjoyable one. The equipment was inexpensive and the outdoor activity was quite amazing, making contacts over 100 miles in distance with this flea power on microwave. The receiver, by the way, was a single 1N23 type diode in the transmitting waveguide, feeding a 30 MHz pre amp and IF single chip FM receiver. This chip receiver was sort of like Dick Tracy's wrist watch radio; a receiver in a single 16 pin plastic chip TDA-7000 device from Signetics.

There have been lots of developments and relevant circuitry changes since our beginnings in the late 1970s when we used wide band FM equipment exclusively; the TDA-7000 WBFM single chip receivers. We still have this equipment today. However it is not used, but is ready for action if there is a need. Generally we take it out for those who still operate WBFM in the ARRL 10 GHz contests held each year in September and October. While WBFM use is declining, it is still a beginner's low cost method to get on microwave operation. Our group still has this equipment ready for use, in keeping with our goal of helping anyone make a contact, whatever mode they might have to use, be it WBFM, SSB or CW. After all, a new mode and equipment for microwave operation is not the easiest to get running right for your first contact. Mastery takes time and experience.

The equipment that The San Diego Microwave Group uses today is a far cry from our modest beginnings and WBFM. I stress that point because we can get so wrapped up with our latest and greatest and forget that there are amateurs who have not developed a system similar to ours. If we become too narrowly focused we will lose sight of newcomers' interest levels; newcomers who can become just as involved as we are now, but first must learn some of the steps we've taken. In other words, don't leave someone behind in the dust. If you are going to form an interest group, be prepared to work at *many* levels of interest. Offer help and answer questions for all who show interest. After all, the primary goal is to have lots of fun with amateur radio.

I thought I would close with a brief description of our latest 10 GHz microwave transceiver club project. As far as I am concerned you can't do better, considering that this unit was converted from surplus material much like our earlier units that were capable of SSB / CW / narrow band FM operation. Our older units were a series of single boards connected with coax, and consisted of about 10 individual modules. The new unit is a single main module with an external synthesizer and power supply. The complete main PC board is 4" by 5 1/2" and less than 1" high. Quite a remarkable system.

The main board uses Gaas FETs for both receive and transmit amplifiers and has two onboard RF mixers, along with a local oscillator (LO) multiplier and LO distribution amplifiers; it's very sophisticated for amateur operation. Comparing the sensitivity and operational condition of this unit to WBFM is like comparing a skateboard (WBFM) to a Lincoln (SSB). With SSB systems our frequency is synthesizer controlled referenced to a stable quality 10 MHz TCXO time base. We have come to expect frequency errors on 10 GHz to be less than our SSB bandwidths of 2 to 3 kHz. In many instances frequency accuracy is in the hundreds of Hz.

This high accuracy frequency removes uncertainty and really helps make contacts. It's almost like 2 meter operation. Experimentation with bounce and reflection paths vs. direct path contacts are a joy to observe with their Doppler and other "special effects" that change the microwave signal. Home brewing, surplus conversion and other factors add enjoyment to our hobby that you can't get ready-made out of any box.

The difference in these new designs, as with any new circuitry, is that the old system must be either rebuilt or discarded for the newer mode of operation. In this case WBFM equipment is not usable or compatible with SSB operation and must exist by itself. The SSB equipment must be constructed from the ground floor and the real penalty is the added cost for circuitry improvements. Did we find that going to SSB was worth it? You bet! I believe if you are bitten by this microwave bug you'll go for it.

Well, that's it for this month. As always I will be glad to answer questions concerning this and other related topics (please send an SASE). I have also set up an Internet connection for questions, notes and updates in general. My Internet address for questions and news is: clhough@aol.com. Until next month, 73 Chuck WB6IGP.

Radio Fun

Communications Simplified, Part 4

by Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

Having looked at the types of signals we may want to communicate, let's next look at some methods for sending them through wires and fiberoptic cables. Some of the methods we will describe depend on ideas and concepts which we will not cover until later; hence this discussion will be fairly low-level. We will fill in some more detail later, as we learn more about the theory.

Wire communications

When you use a wire connection to send a signal from one place to another, you generally need a minimum of two wires to do it. That's because the wire will need to carry some current (even though that current may be tiny), and you need a complete circuit for the current to flow. So is it possible to communicate with just one wire? The answer is yes...sort of. Let me give you a rather interesting example.

When I was in college, I lived in a dormitory where many of us enjoyed listening to music. But this was in the days before compact discs and tapes could give us an hour or more of non-stop music, and many of us were too lazy to get up every 15 or 20 minutes to change the record. So some enterprising student came up with a scheme for wiring up the dorm so that anyone playing a record could feed that music to anyone else in the dorm who would like to listen to it. We had a 12-wire cable strung around the dorm which carried 12 channels of audio (this was before the days of stereo.) Whenever you wanted to listen to music, you'd first look at the 12 wires to see if someone was playing something you liked; only if you couldn't find something interesting would you need to play your own record; if there was an unused wire at that time, you would send your music into it for others to enjoy as well. In a sense, this was a great cooperative effort at community "broadcasting." (It was also fun to have 20 students all place their speakers in the window at midnight, and all play the same bugle call record at maximum volume at the same time. But that's another story.)

Fig. 1 shows how the system was wired. Each of us in the entire dorm would ground our hi-fi system to the radiator in our room. In addition to feeding the speaker, the output of the sender's hi-fi amp (which came from an output transformer) would also go through a 1/8-ampere fuse to one of the 12 wires in the cable; the purpose of the fuse was to protect the amplifier and speaker in case someone accidentally connected the wire to a power line. Anyone wanting to listen to that channel would then connect an AUX input on his system to that wire through a 100k-ohm resistor, which was also there for protection.

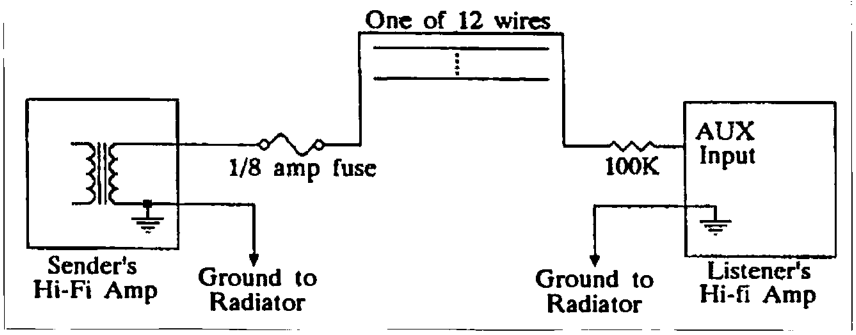

Fig. 1. College dorm music wiring system.

The system worked very well. Some of us connected to the cable with clip-leads, others of us had elaborate switching systems so we could scan or feed the wires just by flipping a switch. But let's look at the system more closely.

First, although this system could be advertised as using only one wire to carry the signal, that's not true. There is another connection that is not so obvious—the ground connection through the radiator pipes. We really had a two-wire system, with the water pipes being one of the two wires. Although we had six buildings tied into the cable, they were all close to each other and all shared the same heating system, so their radiators were all connected together somewhere.

Had the buildings been farther apart, the system might not have worked as well. Although all the radiator and water pipes were eventually grounded (by being connected to some intake pipe buried underground), the earth is not a perfect conductor. (Incidentally, don't count on plumbing being grounded these days—there are enough PVC and other plastic pipes being used that there may not be a connection to ground.) Moreover, there are often other currents flowing in the earth (due to defects or improper power wiring, etc.) which would have caused the grounds in different buildings to be at slightly different voltages. These voltages would have been added to the audio signal, and most likely would have caused hum.

Then too, the 12-wire cable was hundreds of feet long, and snaked on ledges

around the building, through hallways and ceilings, and through basement tunnels. Any time you have such a long wire hanging anywhere, it acts as an antenna and picks up all sorts of signals. Why was this not a problem?

The answer lay in the way each sender's amplifier was connected to the wire. Note that the audio did not come from a preamplifier output or tape output jack—it came straight from the speaker output. An audio amplifier's speaker output has a very low resistance—typically about 1 ohm—and is designed to drive a low-impedance speaker. If the wire picks up noise or hum, the amplifier is strong enough to overcome that and force the line voltage to be whatever the amp wants, not what the noise or hum source wants. In a sense, the sender's amplifier acted as a short on the line, forcing the line to its own voltage and preventing anyone else from affecting it. (For the purists among our readers, the fuse added some extra resistance, but not enough to affect the operation.)

Because of the low-resistance character of the output and wire, it was possible for many students to connect their 100k-ohm resistors to the line at the same time without loading down the line and causing the voltage to drop. As someone connected to the line or disconnected from it, none of us would hear any clicks or volume changes. This kind of a connection, where a high-resistance load is connected to a low-resistance line without any interference is called *bridging*.

Had the output come from a preamp or tape output jack or other "line-level" source, the line would have picked up so much noise and hum that it would have been impossible to use it without some changes.

Shielded wire

One way to prevent an audio signal from picking up interference and hum is to shield it. For example, all the audio cable commonly used between phonographs, tape recorders, and other home hi-fi components (except speakers) is normally shielded wire, such as shown in Fig. 2.

The shield serves three purposes: it prevents outside interference from getting to the inner wire (which carries the actual signal), it prevents the signal from leaking out and affecting other nearby circuits, and it also serves as the second or ground wire, needed to complete the circuit so current can flow.

Shielded wire is used for many purposes, from carrying audio signals to carrying radio frequency (RF) or microwave signals; in the latter case, it is often called *coax* or *coaxial cable*, rather than shielded wire, but the principle is the same. Fig. 3 shows several popular connectors for audio (the RCA phono plug and the phone jack) and for radio-frequency signals (the PL-255 RF connector and the BNC connector).

When properly used, shielded or coax wire does have the advantage of not picking up or releasing stray signals. But it has some disadvantages as well, one of them being that it loses some of the signal it carries. For example, it quite often happens that the signal coming out of such a cable is only half as strong as what went in (or even weaker.) In RF applications, much of this loss is caused by the inner insulator; hence many high-quality cables use air (or even an inert gas) as the insulator, with just a thin spiral-wound strip of insulator to separate the shield from the inner conductor.

"The test current just keeps going forever (at almost the speed of light), searching for a resistor that isn't there."

A second problem, especially in audio applications, is that the shield is so close to the center conductor that there is appreciable capacitance between the two. This tends to short out higher frequencies, so that the cable does not carry high-frequency signals as well as it does low-frequency ones. This reduction of treble response means that this kind of cable is seldom used in lengths over several hundred feet.

A third problem exists in long-distance audio circuits due to the presence of the grounded shield. Audio equipment often has three-wire AC plugs, which ground the cabinet of the equipment through the AC power system. When two pieces of equipment are located some distance apart, these grounds are not directly connected together, and so the cabinets of these two devices may be at a slightly different voltage. When a shielded wire is run between the two, the shield is a second connection between the two cabinets; because of the slight voltage differences, a small 60-Hz AC current flows through the shield and causes a voltage drop. Even though this voltage drop may be just a tiny fraction of a volt, this may not be much smaller than the audio voltage in the cable. This voltage along the shield is then added to the audio signal in the cable, and appears as a hum signal.

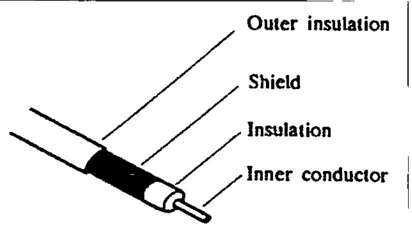

Fig. 2. Construction of a shielded wire.

This isn't much of a problem in a home hi-fi installation, since most home hi-fi components are close together and usually plugged into the same outlet. But it is a major problem in recording and broadcast studios, where signals may have to travel from room to room, or even from one side of town to the other.

Balanced line

Recording and broadcast studios solve many of their wire problems by using *balanced* line, which may be shielded as well, but where shielding is often not even needed.

Fig. 4 shows how a balanced line was used before the days of modern solid-state equipment. With vacuum tubes, the connections to and from balanced lines were usually done with transformers. A center-tapped output transformer would feed the line, and another center-tapped transformer would take the signal from the line. Neither of the two wires in the line was grounded; instead, the ground was connected to the center taps of the two transformers.

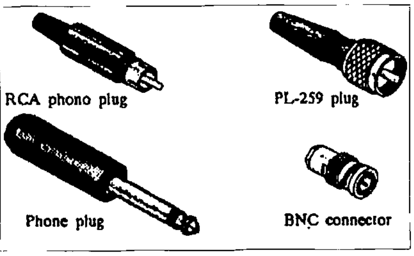

Fig. 3. Several connectors for shielded wire.

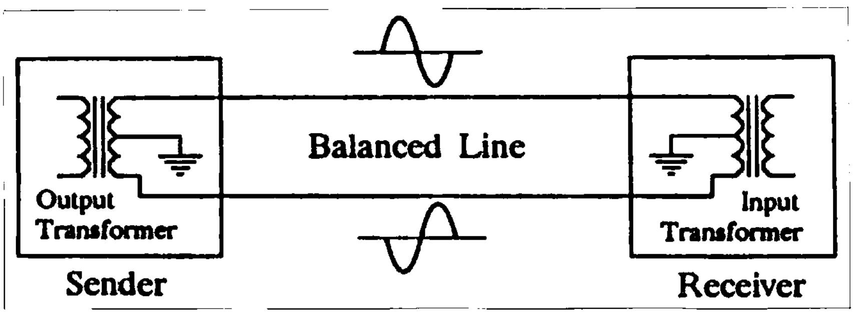

Fig. 4. A balanced audio line.

As Fig. 4 shows, the signals on the two wires are exact opposites of each other—whenever one wire goes plus, the other goes minus by the exact same amount. You can think of this as a seesaw—whenever one end of the seesaw goes up, the other end goes down by the same amount, and the center (where the hinge is—physicists would call it the fulcrum) never moves up or down. We call this type of line a balanced line because the voltages on the two wires are exactly equal (but opposite), so they cancel each other out. (The shielded or coax line, on the other hand, has the signal on the inside lead only, and is therefore called *unbalanced*.)

The input transformer on the right looks only at the difference voltage between the two wires.

Now suppose that there is some external source of electrical noise, which is picked up by the two wires. If the two wires are close enough to each other, they will pick up the same amount of noise. But if both wires pick up the same noise, this doesn't change the voltage difference between them, which means that the input transformer in the receiver doesn't see that noise at all. Shielding is therefore not always needed to keep noise and interference out of a balanced line.

The trick, of course, is to make sure that both wires pick up the noise or interference in exactly the same way. To make sure that this happens, the two wires are usually twisted together, which gives this sort of line the name *twisted pair*. (In fact, one of the favorite buzzwords in modern local area networks is UTP, which simply means unshielded twisted pair.) Sometimes it's interesting to look at some old telephone poles out in the country (or along an old railroad track) and see how they arranged the twisted pair in the old days—see Fig. 5.

There are, of course, some cases where shielding is used in addition to the balanced line. Although the use of a two-wire balanced system cancels out noise and hum, it is not perfect. If the signal is small enough, the noise and hum might still be significant. Thus the microphone cables in recording and broadcast studios are always both shielded and balanced. (Microphone cables in home-type equipment are generally shielded but unbalanced. That's because home-type microphones generally have short cables, whereas professional mikes might be used with very long cables.)

Characteristic impedance

We will look at characteristic impedance in greater detail later, so we will just do it "once over lightly" right now. Think for a moment about how an ohmmeter works. Inside every ohmmeter is a small battery. When you connect the ohmmeter across a resistor, the meter connects that battery across the resistor. Current starts to flow through the resistor, the meter measures how much current there is, and computes the resistance from Ohm's Law:

$$\text{resistance} = \frac{\text{voltage across resistor}}{\text{current through it}}$$

A digital meter computes the resistance in some integrated circuits; an analog meter does it by properly calibrating the meter scale.

Now, imagine (you need a big imagination for this!) that you have an infinitely long length of some cable, such as the flat twin-lead cable used for TV antennas, and you connect the ohmmeter between the two wires at your end. What will you measure?

When you first think about this, you may think that you will measure an infinite resistance—an open circuit. After all, the two wires never touch, so there is no connection between them and therefore no current can flow, right?

Wrong. Connecting the ohmmeter to the end of your cable connects its battery across the two wires. The ohmmeter of course doesn't know whether there is an inch, a foot, or a mile of wire there, so it sends some current out its test leads, hoping eventually to reach a resistor at the end. Normally, the current would reach a resistor after going through just a few feet of wire, and settle down to whatever current Ohm's Law wants. In this case, however, that test current just keeps going forever (at almost the speed of light), searching for a resistor that isn't there. The ohmmeter, however, doesn't know that this test current never reached a resistor; it happily measures the current and voltage, and displays a value of resistance anyway.

The amount of current that flows depends on the kind of cable. Actually, its resistance has fairly little to do with it; it's the capacitance between the two wires, and the inductance of the wires, that mainly determine how much current flows down the cable. The resistance the meter measures therefore depends on the type of cable; we call it Z_0, or the characteristic impedance of the cable.

Different cables have different characteristic impedances—the TV twin-lead is 300 ohms, the coaxial cable used for TV antennas is 75 ohms, while the coax generally used for transmitting antennas is 50 ohms. And the twisted-pair cable generally used for audio and telephone circuits would measure 600 ohms.

Since actually measuring the Z_0 with an ohmmeter requires an infinitely long length of cable, it's not a very practical procedure. But even in shorter lengths, knowing the Z_0 is important because it affects what happens when the cable is connected to a load.

As mentioned above, when we connect an ohmmeter to the end of a cable, the meter sends a test voltage and current down the cable. If the cable were really infinitely long, that current would continue forever. But suppose you cut the cable after some distance, and connect some resistor across the cut end—what happens to that test current when it gets to the resistor?

If the resistor just happens to equal the Z_0 of the cable, then the test voltage and current just flow through the resistor,

and that's the end of the story. The ohmmeter continues indicating the value of Z_0, which is what you'd expect, and that's it.

But suppose the resistor is not equal to Z_0—it is either larger or smaller. Then the test current and voltage eventually hit the resistor, but their values are wrong. From Ohm's Law, the current and voltage would be perfect for a value of Z_0, but the resistance is different and so something has to change. A strange thing now happens—some of the voltage and current bounce off the resistor and start to travel backward on the cable. The resistor is reflecting the voltage and current, and telling the ohmmeter, "Hey, you sent me the wrong values of current and voltage—try again!"

This sort of reflection will always happen if the load at the end of the cable is different from the Z_0 of the cable. This is why engineers often say, "Make sure to terminate (end) the cable in its characteristic impedance." This is the only way to avoid reflections.

DETOUR

Another way to state this is "If the line is more than about 1/100 wavelength long, it should be terminated if you don't want reflections."

The distance a signal travels in the time for one cycle is called a wavelength, and is equal to

$$\text{wavelength} = \frac{\text{speed of the signal}}{\text{frequency of the signal}}$$

The symbol for wavelength is the Greek letter λ. So lines longer than about 1/100 λ can cause problems.

Electric signals in cables travel at somewhere between 65% and 95% of the speed of light, depending on the cable, so about 150,000 miles per second makes a good approximation. If you consider a telephone line carrying audio up to about 3500 Hz, the wavelength is

$$\lambda = \frac{150{,}000 \text{ miles per second}}{3500 \text{ Hz}}$$

which is about 42 miles. So a line longer than about 42/100 miles, or about 0.4 miles, should be terminated. If, on the other hand, the frequency was 100 MHz, then anything longer than a few inches should be terminated.

END OF DETOUR

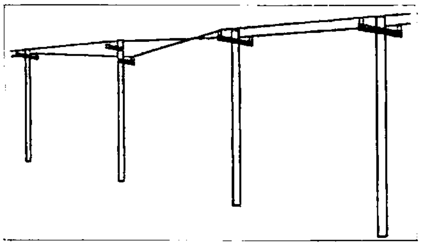

Fig. 5. An old twisted-pair telephone line.

But note that if the cable is short, the reflection may occur so soon that it does not interfere with the original signal. What do we mean by "short"? That depends on the frequencies that are used.

For instance, suppose the signal being carried is a simple 1-volt peak, 1-Hz sine wave signal; that is, a signal which starts at 0 volts, takes 1/4 second to get to its peak of +1 volt, another 1/4 second to get back to 0 volts, another 1/4 second to go to -1 volt, and then 1/4 second to return back to 0 volts. And suppose it takes 1/2 second for the signal to go to the end and the reflection to return to the beginning. Then, just as the +1-volt peak comes reflected back, the input is at -1 volt. The +1-volt reflection and the -1-volt outgoing signal will then fight each other, and this will cause a problem. On the other hand, if the reflection took only 1/1000 second to return, then the outgoing signal would still be pretty much the same, and the reflected signal would not interfere as much. But if the signal was at 500 Hz, then the 1/1000 second delay for the reflection would come at just the wrong time, and there would again be a problem.

The basic rule of thumb is that, if the round-trip time for the signal to get to the end and come back as a reflection is more than a small fraction—1/50 or so would be a rough approximation—of the time for one cycle, reflections can be a problem, and then the line must be properly terminated to stop the reflections. This means that if the one-way time for a signal to get from one end to the other is more than about 1/100 of the time for one cycle, reflections can be a problem, and then the line should be terminated with a resistance equal to its characteristic impedance Z_0.

So let us next discuss the types of cables normally used in communications.

Audio Equipment

Home audio equipment uses plain shielded wire, except to connect the speaker, where the signal is so big that noise pickup is not a problem. Likewise, most cables are short enough that terminating the cables is not important.

Years ago, professional recording and broadcast studio equipment used 600-ohm balanced cables almost exclusively (except for 50-ohm cables for microphones, and unshielded wires for speaker connections.) Broadcast stations still tend to stick with 600-ohm balanced cables, partially because they still use old equipment, but also because they need the benefits of balanced cables. Not only do they tend to send signals longer distances, but many stations also place their studios close to their transmitters, and have the additional problem of having to keep the high-power transmitted signals out of their audio circuits.

But recording studios have gotten somewhat lax about it. There are two reasons for this. One is that the best way to get a balanced line is with a transformer; but recording studios try to stay away from transformers because they degrade the audio quality slightly. The second reason is that there are many small-time studios which operate on a budget; unbalanced equipment and connections are cheaper, especially since home equipment has gotten so good that many studios use a mixture of professional and home equipment. 73

The Tech Side: More Adapters

Michael Geier KB1UM
c/o 73 Magazine
70 Route 202 North
Peterborough NH 03458

Last time, in *Radio Fun*, we were exploring the subject of AC adapters, and looking at how you mate an adapter to an unrelated gadget. Let's continue:

Voltage and current

You've ascertained the proper polarity, and now it's time to deal with the voltage issue. Can't you just match the voltage stated on the adapter to the device's required voltage and be done with it? Sometimes that works fine. Other times, though, you can wind up with problems.

Let's say you have a 6 volt device. How can you be sure it takes 6 volts? Usually, the required voltage will be stated on the case, next to the DC input jack, or it may be on the back, somewhere near the battery door. If there is no marking, count the number of batteries and multiply by each battery's voltage. So, if the device takes four AA cells, you know that's 6 volts because 4 times 1.5 (an AA cell's voltage) equals 6.

Occasionally, you may run into something that requires a higher voltage at the DC input jack than would be given by the number of batteries the gadget uses. I've seen some products that operate from 6 volts' worth of batteries but take 9 volts at the input jack. (Although I've never seen it the other way around, I suppose it is possible.) In most cases, such a device will still work on the lower voltage, but not always. Knowing this, however, is *not* a license to try higher voltages if your hookup refuses to work. Excess voltage can quickly ruin your device! Usually, failure is due to other problems, anyway. But, if you can't get the AC adapter to work, and you've tried all the techniques I'll be describing here, then try and get some service data on the equipment from the manufacturer or others who own the same product, to be sure of the input requirements. Don't just crank up the voltage and keep trying, or you may very well be sorry. There's nothing like that sinking feeling when the unit's lights go out and the first wisp of smoke appears. Remember, electronic circuits operate on smoke: once you let it out, they don't work anymore!

Assuming that you *do* know the correct voltage, here's where the fun begins. Logic would suggest that you could simply match the voltage with the one printed on the adapter, verify the polarity and plug it in. Logic would be wrong. The problem with this scenario is that the printed voltage on the adapter isn't a constant. Almost all AC wall cubes are unregulated. That is, they don't really produce their stated voltage except when at their rated current load. So, if your adapter is rated to deliver 6 volts at 700 mA (milliamps), it may deliver 8 or even 10 volts at significantly lesser load. While you don't need to get the input voltage exactly right, being 50 percent too high is asking for trouble! And, being too low by such a significant amount will probably cause the unit to malfunction, if it'll work at all. In order to get it all working right, you need to know the approximate current demand of your device. Chances are, that value will *not* be printed on the case!

Test it

There are various ways around that problem. If you have a current scale on your VOM (volt-ohm-milliammeter) and a variable power supply, you can simply feed the gadget the correct voltage and measure its current draw. Remember, the meter's leads go in series with the power supply, not in parallel across it. Although it usually won't matter which lead you choose to interrupt for your current measurement, use the ungrounded one, usually the positive, to be sure you don't cause a ground loop (an unwanted flow through an alternate path), which could confuse your reading and, in rare circumstances, even cause damage to your device.

If your shop is not so blessed with gear, there are some other things you can try. Take an adapter rated for the required voltage, with the smallest current capability you can find. Hook it up and try it, remembering to observe the polarity. Most likely, it won't put out too much voltage; it'll probably be too low. If the device works fine, you're home free, as long as the adapter doesn't seem to be heating up a great deal. If, though, it exhibits AC hum or seems weak in some way, it has given you a valuable piece of information: Your device requires more current than this adapter can deliver! Make a note of the adapter's current rating and try another one, this time with a higher current capacity.

Eventually, you'll get to one that works. Or, if you don't have any others, you can use your measurements to deduce how to use what you have. If, for instance, you need 9 volts but have only 7.5 volt adapters, try using one with a fairly high current rating. That way, it may put out something around the 9 volts you need, because it can supply more current than is required, raising its voltage above the rating.

Going the other way, though, is asking for trouble. *Don't* use a 9 volt adapter with a small current rating to power a 6 volt device, with the idea that the excess current demand will lower the adapter's voltage. It will, but it'll also cause AC hum and, more seriously, heat up the

Welcome Newcomers!

Wayne Green W2NSD/1

With the facts of life telling me that around 95% of ham newcomers these days are dead-ending on 2m, maybe you can give me an idea of how to get them excited enough to upgrade and join us old timers down on the DC bands. I've tried pointing to the adventures that hamming has provided for me. "Oh, there goes old Wayne blowing his horn again."

On the other hand, if the spirit of adventure has either been blown out, or has never been kindled in their minds, I'm wasting both my time and theirs. Almost anyone can learn the stupid code and get the Advanced Class ticket and enjoy everything hamming has to offer.

Yes, of course it takes money to go on DXpeditions, but if you have a spirit of adventure and the ability to work for a goal, making money is a snap. It's this spirit that gets a treasured few hams to be active on our satellites, helping packet grow and speed up, winning contests, and so on. It's the spirit that gets people to read and learn. It's this spirit, according to Ray Kroc, the chap who gave us McDonald's, that determines winners and losers in life.

I've spent a lot of time up here on my soapbox, waving my arms and trying to get hams to take advantage of the world of adventure hamming provides. Eyes glaze over. Yawns. I want to get as many people to share the excitement and adventures I've experienced, so I talk at conventions and write about the things that have helped make my life so interesting. The fun of hearing your voice come back from a ham satellite, delayed a little by the distance. The thrill of downhill skiing when you're good at it. The indescribable feeling of scuba diving on a coral reef. The exhilaration of beating down a pileup from some weird country. The feeling of making a 10 GHz contact in another state while freezing your fingers on top of a mountain. The joy of hearing ragtime piano played by an expert. The rapture of reading a book and learning something new.

These are feelings that movies and TV can't evoke. Oh, there have been a few darned good movies, but even the best don't compare with the feeling you get from working country number 330 or making that slow scan contact with the Canary Islands. Or an aurora contact on 2m a thousand miles away. Or a moonbounce contact with VK3ATN or HB9RF.

The code? Sure, let's keep plugging at getting rid of that obstacle, but in the meanwhile stop using it as an excuse. Yes, I know, you have dyslexia or some other stupid excuse. Just shut up and use my method to learn the code. If you're too cheap to buy my code tapes, then get a program for your computer that will send the code at 13 or 20 per and save the $7.

No, I'm not at all in favor of lowering the standards, just in getting rid of an artificial barrier which these days has nothing to do with technology. This is a high-tech hobby. We should be using it as a gateway for kids to get started learning the fundamentals of electronics and communications. The 21st century is going to be unforgiving of people who are not high-tech literate. And what more fun way to learn than by amateur radio?

In the past all of the major discoveries and pioneering in radio communications was done by amateurs. We pretty much stopped doing that 30 years ago, thereby abrogating the lease requirements for our ham frequencies. Fortunately our landlord hasn't noticed that we've stopped paying the rent. But the increased pressure from commercial interests who want our bands may eventually get through. Money talks, and we're beggars, living on past glories.

1200 baud packet? Give me a break! 28,800 baud is getting to be the standard on the Internet and 56k is coming along fast. So what have you done to help get us up to speed? Yes, I know, you have an HT on your belt. Well, I did that back in 1969. Heck, I had my own repeater on Pack Monadnock Mountain in 1969, providing contacts over almost all of New England. And that's almost 30 years ago. More than a generation.

If you put your mind to it you could be an expert on packet in a few days. Weeks, at the worst. If they can cram 56k baud over a crummy phone line, you should be able to zip it over the air without dropping a baud, and never mind tropospheric multi-path distortion.

Quiz: how many words per minute are 56k bauds? Now where's my trusty old hand key? With some decent baudy work a DXpedition could flatten a pileup in seconds.

I've done some research that you haven't bothered to yet, so I know how to cure almost every human illness and to live to 120 or so in good health, so if by some magic we manage to hold on to some ham bands, I expect to be one of the pioneers who helps us develop a system where we'll be able to work every licensed ham in the Callbook in one day. And they'll all be reachable, too. Or at least their stations will be.

I've been writing about health in my editorials. How about an antibiotic which microbes can't mutate to avoid? One that you can make at home for fractions of a cent? The medical industry is going to go bananas if word of this gets out.

How about a cure for any blood-carried illness that costs pennies to use? One that'll wipe out any virus, bacteria, fungus, or parasite in the blood? I'll be writing more about all that. You'll still be able to fall off your tower or get across the final plate voltage and expire, but it won't be the slow, lingering death most people are suffering.

Well, that's just one of my recent interests. I'll tell you more about all that on 20m, or if I get invited (all expenses paid) to talk at a hamfest near you. Yes, of course I'll talk about amateur radio too.

Radio Magic

by Michael Bryce WB8VGE

Troubleshooting Your New Kit

What do you do when the darned thing doesn't work?

Still can't find out what is wrong with your new kit? Often another person can spot something you have been passing over. However, if even that doesn't work, then let's dig out the test gear and see what we can find. Here's the drill. Say the project is not entirely dead, but just not working like it should be. Really "dead" kits are usually easy to fix.

The first place to check is the power source. It may be as simple as a 9 volt battery, or as complex as a switching-regulator supply. Let's check to see if there is voltage coming out of the source and if that voltage is enough to operate the unit. A digital VOM comes in real handy here. If you don't have one in your tool box, it's time you did.

Attach the black lead of your VOM to the ground side of your unit with a clip lead. Radio Shack™ carries a nice selection of clip leads, so pick up a bag or two. The ground is normally the negative side of the battery/power supply or the common ground bus around the PC board.

Now, with your VOM's positive probe, touch the positive side of the battery or power source. Let's use our example of a 9 volt battery. Your VOM should read at least 8 volts or higher with a fresh battery. Now, turn your kit on. Did the battery voltage drop way down to, say, 5 or 7 volts? It did? Well then, either you need a fresher battery, or you need to take a closer look at the current flowing to the unit. To do this we need to switch our VOM to display current and insert the VOM in *series* between the battery and our kit. This is simple to do when you're using clip leads. As our project is running from a 9 volt battery, it's easy to snap off one battery clip and give it a slight turn to expose the now bare battery terminal. It makes no difference which battery terminal we use—the digital VOM will read the current either way. If we connect the VOM up backwards it will display a "-" to the left of the display. This of course only works with a digital VOM and not the older analog types.

Attach one clip to the bare battery terminal and another to the battery clip. Select current with the VOM switch and then select the proper current range. Since this device is running from a 9 volt battery, select one of the lower current ranges. It is good practice to select the highest current range and then reduce the setting until a valid reading is obtained. A 500 to 200 mA range is a good start. It's only a 9 volt battery, so your unit shouldn't draw a lot of current.

Turn on the power switch and note the current being drawn on the VOM's display. Hmm, the meter reads 80 mA, so now we can see why the voltage dropped. That's a lot of juice for a single 9 volt battery. They are designed for loads of just a few mAs to maybe 20 mA on the high end. But 80 mA? Nah, that's way too much current. And that means you have something drawing all this current. All you have to do is find what's doing it. You've got about a 112 ohm resistance from B+ to ground in there somewhere instead of 450 ohms or more.

Some possible causes are a shorted output device, audio amp, or RF amplifier; electrolytic capacitor(s) installed backwards; leaky electrolytic capacitor(s); IC chip(s) installed backwards or in the wrong location; the voltage regulator installed backwards or in wrong location; a solder bridge between two or more PC traces; or even the battery installed backwards.

"Even with the simplest test gear, we have been able to determine several causes and their fixes."

Or let's say we measured the battery voltage and it did not change when we turned on the unit. We connected our VOM to read current and the current displayed was zero. So what's wrong? There must be a break in *series* with the supply. Let's look for some possible causes such as a broken battery connector, a reverse-polarity protection diode installed backwards, a bad battery wire solder junction to the PC board, a solder flux insulator around the plus supply wire on PC board, a defective crimp on connector, or the battery connected backwards.

Of course, in both cases, it is possible to have another problem causing either excessive current or no current. But check out these quick fixes first.

When there's excessive current flowing, there is a good chance you can feel for the defective part. Even at only 60 mA, something is going to get warm. So, with your fingertip, carefully touch each part to see if it is running warm or even hot. *Don't do this test with any piece of gear running from a 110 volt supply or one with high-voltage circuits inside.*

If you come by a component that is hot to the touch, then turn off the project and take a closer look at that section. Remember, the hot part may not be the fault. It may be running hot because of something else down the road.

It's very easy to swap a small three-terminal voltage regulator with a transistor. They look the same, but are hardly interchangeable! If this fate befalls you, then you can bet the farm that the regulator is cooked. Luckily, they're not very expensive. You have to remove the one already installed backwards, so you may as well replace it with a brand-new device. The lesson here is: If you hook up a solid state device backwards or install it incorrectly, it's more than likely bad. Just replace it and put the whole mess down to experience!

The above examples point to two fundamental facts about current and voltage. Even with the simplest test gear, we have been able to determine several causes and their fixes. 73

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

When OSCAR-1 was launched nearly 35 years ago, amateur radio operators didn't have computers for orbit predictions. The chore was attacked with slide rules and pencils. With a few pieces of information, it was possible to predict when the satellite would be within range, but the process was tedious.

During the next decade special maps and clear overlays were used to predict satellite positions. Using an OSCAR-LOCATOR kit and a few simple pieces of data (equator crossing time and longitude of crossing), tracking was relatively easy and inexpensive.

The late 1970s and early 1980s marked the arrival of the home computer for satellite pursuits. While many new owners of Radio Shack TRS-80s and early Apple computers were wondering what to do with their new and expensive toys, hams were tracking satellites with ease and incredible accuracy. Even Sinclair ZX-81 fans could plot the paths of complex orbits.

Today's PCs make satellite tracking a simple task. Many software packages exist that not only predict access times, but provide real-time simultaneous tracking of many satellites with graphical earth views and automatic antenna pointing. Most ham radio BBSs and ham-oriented Internet sites (try ftp.amsat.org or http://www.amsat.org) have some shareware and freeware programs that will do the job.

The numbers

One thing that all satellite tracking methods have in common is the need for orbital data to characterize a particular satellite's position in space at a given time. This data is commonly referred to as "Keplerian elements" or just "element sets."

Due to atmospheric drag and other effects and inaccuracies that accumulate with time, new element sets are needed to maintain the prediction accuracy of the software. Some satellites with high, stable orbits may only need new data once a year, while other low orbit objects with changing orbits, like the MIR space station, could use a new set every week.

Table 1 shows an element set for AMSAT-OSCAR-13 presented in standard "AMSAT" format. Many satellite enthusiasts get element sets for all the satellites they wish to track from packet radio, BBSs or the Internet, usually the same sites where tracking software is found. The element sets are in a standard text file that can be placed in the same directory as the tracking program. The program typically has a menu choice allowing automatic updating of its satellite database from the element-set file.

With such an effortless process to get new data running, it's understandable that many users are not aware of the meaning of the numbers. It's not necessary to have a degree in mathematics to work with element sets, but some knowledge of their significance is useful. Sometimes blatantly bad element sets are released, or satellites are given the wrong identifier shortly after launch. A quick look at the element set may reveal a ridiculous Decay rate or impossible Mean motion.

The set in Table 1 describes an orbit that is elliptical with a high apogee occurring over the northern hemisphere. There is very little atmospheric drag and the time to make one orbit is just under 12 hours. A description of the individual elements can explain these quick observations and more.

Epoch rev							5	8	0	1					
Checksum								3	0	6					

Table 1. AMSAT-format Satellite AO-13 element set.

Satellite:

The first entry is an informal name that is distinct to this satellite. AO-13 is also known as A-O-13 or AMSAT-OSCAR 13. The "OSCAR" part of the name dates back to the first ham radio satellite, OSCAR-1, and stands for Orbiting Satellite Carrying Amateur Radio.

Catalog number:

NASA assigns formal identification numbers to all man-made orbiting objects. Vanguard 1, launched on March 17, 1958, is still in orbit and has Catalog number 5. AO-13 was launched on June 15, 1988 and is listed as Catalog number 19216. The Catalog number should not be confused with the International Designation number which specifies year of launch, launch number since the beginning of the year and object letter identifier. AO-13's "ID" is 1988-051B.

Epoch time:

Note the example in Table 1. The Epoch time is 96011.38475840, defining the moment when all of the numbers in the element set were measured or derived. This corresponds to year 1996, day 11, followed by the "decimal day" of 0.38475840. Using the fact that there are 24 hours in a day, 60 minutes in an hour and 60 seconds in a minute, the "normal" time format can be found as 9 hours, 14 minutes and 3.126 seconds. Thus 96011.38475840 is the same as January 14, 1996, at 9:14:03 UTC. UTC stands for Universal Coordinated Time. If you are not already logging your ham activities in UTC (same as GMT), working with satellites will provide the needed boost. All satellite predictions use UTC. Conversion to local time zones is a feature incorporated in most software.

Element set:

This entry identifies the element set. Set number 134 is obviously more recent than set

130. Sometimes the set number may include other clues as to its origin. James Miller G3RUH has been releasing "smoothed" element sets for AO-13 and AO-10 that represent averages of several NORAD/NASA sets. The G3RUH sets' accuracy over time is better than the NORAD/NASA sets' and have names like RUH8-95, for a G3RUH set done in August 1995. Space Shuttle sets may also have letters in with the numbers, depending on their origin.

Inclination:

The inclination of a satellite's orbit is the angle of the path of the orbit as it crosses the equator of the earth while moving south to north. A polar orbit that travels from pole to pole will have an inclination near 90°, while a satellite that follows the equator will have an inclination near zero.

RA of node:

The RA of node or RAAN is the Right Ascension of Ascending Node. This element is one of the most difficult to understand. A simple definition describes RAAN as an angle that specifies the orientation of a satellite's orbital plane with respect to the fixed stars. The satellite's orbital plane is relatively easy to visualize. The difficult part is to envision the creation of an angle between this orbital plane and the "fixed stars." In the case of the NASA element sets, the line to the "stars" is drawn from the center of the earth to a star in the constellation Aries. The angle defined by the intersection of this line and the satellite's orbital plane at the time of the Epoch is the RA of node.

Eccentricity:

The Eccentricity term refers to the shape of the orbit. No orbit is exactly circular. If it were, this element would have a value of zero. The Eccentricity of AO-13 for the element set in Table 1 is 0.7366043. This shows that the orbit is highly elliptical. Due to the influence of the moon, AO-13's orbit is becoming more elliptical every day. Most tracking programs cannot predict this change due to their inability to handle gravitational forces beyond the earth-satellite interaction. For most ham pursuits, this is not a serious problem, except when a satellite crashes to the earth, like AO-13 will, in December of this year. Updating the element sets each month until the end will at least provide accurate tracking predictions for making contacts and enjoying this orbiting resource as long as possible.

Arg of perigee:

The Argument of perigee is another "difficult" element. It describes where the perigee (or low point) of the orbit is located in the satellite's orbital plane. If the perigee occurs when the satellite is crossing the equator on a south-to-north pass, the angle from the equator to the perigee point is obviously zero (they are occurring at the same place), therefore the Argument of perigee would be zero. The apogee, or high point of the orbit, would occur 180° (half an orbit) later, also on the equator.

For the example in Table 1, we have an Argument of perigee of 28.7607°. This means that AO-13's perigee is occurring 28.7607° after crossing the equator while headed north. The apogee is thus occurring below the equator, half an orbit later.

Mean anomaly:

Mean anomaly locates the satellite in its orbital plane at the time of the epoch. All programs use standard astronomical convention for this element. The satellite is at 0° or 360° at perigee and 180° at apogee. In our example the value of 356.7587° is very near perigee for AO-13 at the Epoch time noted.

Mean motion:

This element simply specifies the number of orbits (perigee to perigee) the satellite makes in one solar day (1440 minutes). In the example, AO-13 is making slightly more than two orbits per day, thus each orbit is a little less than 12 hours.

Decay rate:

The Decay rate of a satellite's orbit is also defined as the rate of change of Mean motion, the first derivative of Mean motion, or as the drag factor. It provides a correction to the Mean motion that accumulates with time after the Epoch of the element set. Satellites with high orbits have very little orbital decay, while objects like the Space Shuttle or MIR have significant values associated with this element due to their low orbits and corresponding atmospheric drag. The Decay rate in the example is a very small negative number shown in scientific notation. The -4.44e-06 value can also be written as - 0.00000444 rev/day/day (orbits per day squared). The negative value in this element set for Decay rate is not typical but may be a result of gravity pumping or caused by the method of data collection by NORAD.

Epoch rev:

This is the orbit number. While satellite enthusiasts used to keep close accounting of orbit numbers for QSL cards and logs, this is no longer the case. In many instances, the orbit number shown in the NORAD/NASA element sets will differ from calculated values. Differences occur due to the definition of orbit number 1, or is it orbit number 0? The question of when the orbit increments also comes up. Do we increase the count by one when the satellite passes through perigee or when it crosses the equator on a south-to-north pass?

Checksum:

This is simply a math function to verify the validity of the numbers in the element set. It is the total of all the individual digits in the set. Some programs use the checksum. If the checksum value and the total of the digits match, the element set is assumed to be correct, at least the data is assumed to be the same as when it was first calculated.

The Tech Side: More

Continued from page 70

adapter, possibly to the failure or meltdown point! It's normal for AC wall cubes to get warm with use, but they shouldn't get hot. Lots of heat is a dead giveaway that you're trying to pull too much current from an underrated adapter.

Wrap it up

Once you've matched the current capacity of the adapter to the device you want to power, you should be all set. Connect it up (don't forget that polarity!) and it ought to work fine. While it's running, measure the voltage across the DC plug; it should be within a volt or so of what the product needs. I prefer to err on the low side, because of the lessened chance for harming my gadget, but, as long as you're close, you should be OK. Remember, the original adapter probably wasn't any closer! I've taken measurements on plenty of circuits, and I've seen many original-equipment adapters off by as much as two volts. As far as I'm concerned, though, that's a lot, especially if it's on the high side.

I hope you've enjoyed this look at AC adapters. If you're at all like me, you'll use this information often; I can't count the number of AC adapters I've rigged up. With this in mind, look around at the next hamfest for cheap adapters for your junque box. I always keep a good supply, and I always wind up using them! Until next time, 73 from KB1UM.

NEVER SAY DIE
Continued from page 63

to de-license the reason-challenged hams (oops, I slipped and used the word "challenged." The last time I used the term "reason-challenged" I got angry letters from several crippled hams who went ballistic over my using the term "-challenged" and claiming that, just as they suspected, I was anti-crippled hams) as it is for them to get their license, we might be able to clean up our bands. But when we have hams who cause three years of aggravation, who force the ham clubs to go to court to get a restraining order, and then harass the repeater anyway, and to hell with the court order, it's time to see if we can get the FCC to make it easier to take ham tickets away than to give someone the death penalty.

I suppose you're going to sit and nod. Yep, Wayne's right again. Well, how about sitting down and going to work to get Part 97 changed so we can get rid of the scum, even if they can copy the code real good.

We seem to be able to get enough idiots licensed so that ring-leader jerks are able to recruit others of even lower mentality. We had a whole set of scum busy wasting 14313 for us, doing everything in their power to shorten the life of the hobby for all of us. Well, we deserve every hit we get if we're not smart enough to shut these turkeys down by ourselves, instead of going mewling to the FCC for help, which has more than enough to do without wiping our tushes for us. Hey, shouldn't our national organization be *doing* something for us?

And we seem to be able to endlessly put up with the hot air and self-promotion emanating from Maine all hours of the day and night. Can't we get him to settle for a web page? Somehow I think the pioneering spirit that founded this country got killed by our 60s school system, leaving us with almost no one who will stand up and fight for what's best for us.

I suppose the Viet Nam war did a lot of that too. In WWII we knew what we were fighting for and we all pitched in. As I've mentioned a few times, 80% of the hams joined the military.

Grumble.

Instead of wasting all that time and money with a repeater war, why not shut the darned thing down, take up some other hobby and stop screwing things up for everyone? And that goes for both the bad guys and the righteous. A pox on both your houses.

A Limbaugh limiter

Reader Louis Burkhardt N5LTP, of Los Alamos NM, suggested a product which might sell like burritos. It's something any dyed-in-the-wool ham should be able to put together. It's a radio talk show commercial filter. By the time you sift out the commercials, Rush's three hours will boil down to almost listening length. Ditto Liddy, and anyone else you're addicted to.

The hard way would be to sense the louder voice from commercials, but I suspect if you check the clock you'll find that the commercial and news breaks are fairly consistent day to day. If you time the Limbaugh breaks for one day the pattern will probably hold pretty well for months. That's how the stations carrying his program know when to run their commercials.

There's an outfit making a tape recorder to capture three hours of voice quality on one tape, but the price is high. I think it was around $200, which I'd rather spend on a 30-day pass to fly around the Caribbean. How about a circuit to cut a three hour radio talk show down to 90 minutes so I can set a C-90 cassette going and build a library of Art Bell shows? Or Laura Lee? Or anyone else that's running shows I shouldn't miss, but which you negligently have failed to let me know about.

Once you invent these, I'll bet there'll be a good market for them.

XYL maintenance

Many perfectly nice but näive women marry hams with no idea of what they are getting into. Sure, there are a few hams who can take it or leave the hobby. But many more are far more interested in amateur radio than in their marriages. Or even their families. I remember running a cover cartoon on *CQ* when I was the editor showing a ham sitting in front of many relay racks of equipment while his wife and baby were standing behind him in rags.

Sure, it was funny because it was an exaggeration. But a good part of the humor was the underlying truth of the situation. Hey, guys, try to remember that amateur radio is a hobby. It's for *fun*! You'll have a lot more support for your hobby if it isn't perceived as a competitor for your wife's affections.

Several hams I've known personally were divorced by their wives with ham radio named as the corespondent.

When's the last time you took the XYL out to dinner and a movie? Or, if you're thrifty like me, to a matinee and then dinner? Or maybe read the non-ham parts of my editorial to her? When's the last time you took her dancing? I have a secret I'm going to share with you: wives love romance, not rigs or nifty HTs. And nothing says romance like dancing.

Oh, you've forgotten how to dance? Then get a how-to-dance video, put it on, grab her and you'll soon have a very happy wife, with a sparkle in her eye and the bedroom in mind. The effect has been known to last for days. No fair doing this just before trying to get her to agree that you really should have a new rig. But after you've taken her out to a couple of dances she might bring up the new rig subject on her own.

Where do you get dance videos? I thought you'd never ask! They're one hour lessons and cost $42.95pp from Butterfly Video, Box 184, Antrim NH 03440. Call 800-43 DANCE for a catalog showing the nearly 100 different kinds of dances available. They even have some for kids. They've got 'em for rank beginners right on up to competition dancers. In this way you can romance your wife at home while you're learning, practicing when it's handy for you instead of going out to a class (which usually costs a lot more). And you can brush up when you've forgotten something.

I've several friends whose wives hate hams. None of them ever take their wives out dancing. Bet on it. Our hobby should be seen as that and not as a competitor for your wife's and kids' affections.

I recommend the Butterfly Videos because they're so outstanding, and I've seen 'em all. Kathy Blake is the teacher and she's won all sorts of prizes. But most important, she knows exactly what questions you're going to have and what problems, so she makes it simple and fun to learn.

Okay, now you can go back to your shack and find a pileup to molest.

Like to make some money?

I'm looking for a few go-getters to sell *73* subscriptions at hamfests. There are tons of hamfests, picnics, auctions, flea markets and other ham events where you could set up a table and make a few bucks on a Saturday. You should be able to pick up from $100 to $500 a Saturday. Remember, far too many hams aren't yet subscribing to *73*, and every one of 'em should be...and might, if you get after 'em.

Plus you can sell some of my books too (on commission). My list of "73 books you're crazy if you don't read" is selling like Big Macs. Well, at $3, even if they only buy one of the books I recommend, they'll get their money's worth just finding out about it. Then there's my "Declare War" book, subscriptions to *Cold Fusion*, and the booklet describing how to make a blood purifier which Bob Beck claims will not only completely cure AIDS, but also any blood-borne disease such as herpes, cause your body to get rid of excess weight with no dieting, and even regrow hair for male pattern baldness people.

The midwest territory is taken, but I could use energetic help in the Northwest, Northern and Southern California, the mountain states, the Southwest, the South, the Eastern Seaboard, and the Northeast.

There's quite a lot of interest in a $5 booklet I wrote recently as a result of requests from listeners to Art Bell's (W6OBB) talk radio show. This is "How To Make Money, A Beginner's Guide." Well, once you know the secret you can get out of the rut that 99.99% of the people are in, a rut of thinking that results in your never having very much money. It's a rut that is deeply engraved in our subconscious by our blessed school system and media. The more rich hams we have, the more clout we'll have with the FCC and congress.

I'm looking for hams who will get out there and not miss a hamfest within driving distance. Anyone want to help shake the money tree on Saturdays for me?

Falling behind

I can remember when we hams were in there first with new technologies instead of following far behind commercial developments. We hams invented FM and then NBFM. We invented practical sideband. But now the world is going digital and we're still fighting over CW.

Our telephones are going digital. Our hi-fi went digital over ten years ago. Now broadcast stations are going digital in one country after another. Blaupunkt, Grundig, Philips, Sony, Pioneer and Kenwood all either have receivers on the market or will have soon. No, no American companies.

With digital, each transmitter can broadcast five programs of CD-quality sound, plus data such as a newspaper. The conversion of AM and FM to digital will, I expect, happen faster than anyone imagines, just as we saw the LP become almost extinct overnight when the CD was introduced.

Some digital tests are being conducted in San Francisco, so we'll see how they go. The early tests in England ran circles around both AM and FM broadcasting in quality and coverage, as I reported several years ago.

There must be some readers who are working in this field who can help the rest of us come up to speed. Maybe with ideas on how we hams can start experimenting with digital voice communications. I'd like to see articles submitted for me to publish so we won't keep falling further and further behind the commercial state of the art. After all, it says in the lease for our ham bands that we're supposed to be leading in technology, not kicking and heel-dragging to stay 40 years behind the commercial world.

Meanwhile, people in Britain, Denmark and Sweden are already enjoying digital broadcasting, with France, Hungary, Australia, Netherlands, Canada and Mexico not far behind.

A dying breed?

With under half of our surviving hams (45.5% now) having better than entry level licenses, and with the majority of "hams" having no apparent interest in ever upgrading so they can work the low bands, perhaps you can understand why I've been researching more and more into ways to help us aging survivors add a few more years to our lives. The politically correct, who can go jump in the lake, can call me elitist, for feeling sorry for the 54.5% of our licensees who have isolated themselves into what is increasingly being called an HT-CB band.

Sure 2m and repeaters are fun. But when I started promoting repeaters in 1969 I never thought that this activity would eventually dominate the hobby. My aim was to revive a dying hobby. What I hadn't recognized was that the almost complete elimination of our school radio club infrastructure by the ARRL's 1964 "Incentive Licensing" proposal to the FCC would permanently end our ability to attract youngsters into the hobby in any real numbers.

So, in between hectoring you to get the Techs to come to your club meetings and encourage them to upgrade, and getting on 2m yourself to help inculcate these new arrivals with our ham culture, I've been finding out all I can about how what's left of us can lead longer, healthier, and yes, maybe even happier lives.

As I've researched more and more about health, I've been recommending you read the most important books I've found. The more I've looked into this health thing, the more I'm convinced that if we can change some destructive eating and living habit patterns, we have the potential for living healthily to 120-150 years. But the obstacles are monumental and at times discouraging. Habits run deep. It seems like most people would rather enjoy a Big Mac now and endure years of chronic illnesses than live 75 more healthy years later on. How do you convince a 13-year old that starting a smoking habit now can lead in about 40 or 50 years to a nursing home with an oxygen bottle always at hand. How do you get people to stop drinking fluoridated tap water which may eventually turn them into Alzheimer veggies in nursing homes, not even able to recognize their own children or spouses?

If you read some of the books I'm recommending I think you'll find that every chronic illness can be attributed to either a nutritional deficiency or to our slowly poisoning ourselves one way or another. And with the average age of the General and above class licensees getting up into the 60s, unless I can convince them to break their destructive habits, we're goners. Pity, too, now that the short waves are increasingly being deserted for the microwaves and satellite communications. Pretty soon, what few are left of us will be about the only ones using the 3-30 MHz part of the spectrum. We might eventually get back our 7-8 MHz and 14-15 MHz bands. And then everything else except perhaps the WWV and CHU channels.

Of course, like the 13-year-old smoker, we're ignoring the inevitable loss of our most valuable future bands. Well, that's our legacy to the coming generations, like the national debt and the using up of coal, oil and other natural resources. Who really cares what happens to our 10 and 24 GHz bands? Our vision ends either tomorrow or next week some time, as it does with our health.

When the Bob Beck blood purifier turned out to cause people to lose weight without changing their eating habits, there was a rush to build and use these simple electrical gadgets. The key point was that then an eating habit didn't have to be changed. Yes, I agree, it takes a lot of determination to change habits.

I was a skinny kid until I got vaccinated. Then suddenly I developed a whole range of allergies and got fat. And I stayed fat until I was 50, when I finally decided to break that habit. I cut back to a 1500 calorie a day diet and took off over 85 pounds over nine months. 23 years later it's still off. I broke that damned habit. My approach was much like that used by Alcoholics Anonymous. Don't break your determination for anything. Not once. None of that "I'll eat that chocolate sundae today and diet tomorrow" crap.

Once you have discovered that under all that moss back there is a backbone, you can exercise it more. Use it to get you out every day for a couple miles of brisk walking. Use it to break away from the deadly pattern of always working for someone else. It takes real guts to break away from the protection of a weekly paycheck. Until the company downsizes and you're suddenly on your own. Then you blame everyone but yourself for the fix you're in.

Big companies downsize to get rid of older employees, replacing them with much less expensive and more flexible younger people. Or computers. Smaller companies go out of business. The steady lowering of communications and shipping costs puts you in more and more direct competition with a worker in Taiwan or Pakistan. And these competitors for your job work cheaper, and are better educated than you, since you've allowed your school system to sink to the worst in the developed world. You're unlikely to have either security or make much money working for others. But it's a powerful habit to break. I've been there, done that, so I know how it feels.

Even if you can't wean yourself from the comfort of a company paycheck, you can at least start breaking some eating habits and have a better shot at living in poverty on Social Security.

To the moon, Alice!

The hot fusion scientist welfare crowd is almost getting panicky over their lack of progress. They've wasted billions on fruitless attempts to fuse lighter weight atoms, thus generating energy. Indeed, I've published some papers in *Cold Fusion* showing that not only has there been almost no hot fusion progress, but that the future seems just as grim.

But now these poor old guys have a straw to grasp. Thanks N3RF for faxing me news of the fusion conference where they are looking hopefully to fuse deuterium with helium-3 (^3He) to make lithium. The only drawbacks seem to be the cost of deuterium, which ain't cheap, and the lack of ^3He. Hey, no problem! It turns out that there's tons of ^3He on the moon. So they're working on plans to ship helium back from the moon. Now that's a great Alice In Wonderland project and well worthy of our federal welfare scientists.

Yes, we do have a serious need to find a new energy source. Our fossil fuels are going to run out within a hundred years and there seems to be some small element of guilt about doing that to our grandchildren. And fission does generate some awful byproducts, for which we have no good plans other than to dump them on our grandchildren and let them worry about it.

Meanwhile, Japan has increased their national investment in cold fusion research from \$7.5 to \$100 million a year! Indeed, I'm getting most of my papers for *Cold Fusion* magazine from Japanese researchers. Our Department Of Energy is still doing its very best to prevent any American research in this field, while pouring billions into hot fusion research via a few chosen universities. Another testament to lobbying power on congress. When can

I get you to sign on to the new NRA? That's Never Re-elect Anyone! Please help flush that stinking Washington toilet you've let clog up.

We're doing pretty well, considering. We're on track to use up hundreds of millions of years worth of fossil fuels in around 150 years. My great-great grandfathers were alive 150 years ago. My father was around when the first cars got going. And I remember my family's Model T. It looks as if my grandchildren will see coal, oil and gas as rare, expensive resources. Wiped out in a cosmic blink of the eye.

Fluoridation - II

In my February editorial I reviewed a book on the dangers of fluoridation. Well, there's poor old Wayne, crying about the sky falling again, right? Maybe you shouldn't bet your life on it. Hey, I thought I was wrong once, but I found out that I was in error.

Yes, fluoride does help children's teeth. But what about the downside toxic effects the ingestion of this poison has, such as hardening of the arteries, increased brittleness of the bones, and the effects on the brain? A recent study from the Department of Toxicology, Forsyth Research Institute, the Department of Pediatric Dentistry, Eastman Dental Center and Veterinary Diagnostic Laboratory, Iowa State University have confirmed the public health malpractice and quackery many doctors have been concerned about for years.

The report cites Chinese scientists who found that a fluoride dose of only 3-11 parts per million (ppm) could effect the nervous system directly. This is well within the amount of fluoride millions of us are getting in our municipal water supplies. Add to that fluoride in toothpaste and mouth rinses, and in our cola drinks, commercial beverages, dietary supplements and even in everyday food.

Another Chinese study showed that fluoride affects our attention spans. American researchers had to make do with rats for their experiments, but they found that fluorides caused behavioral disruption in rats. Prenatal exposure caused cognitive thinking and drug-induced types of behavioral defects. Worse, they now suspect that fluorides, possibly in conjunction with aluminum, could be the root cause for the recent enormous increase in Alzheimer's disease. Right now about one old person in three can look forward to that horror!

The study concluded that fluoride levels acceptable to health departments and dental organizations can cause motor dysfunction, IQ deficits and learning difficulties in humans. Just what we need to add to our worst in the developed world school system and endless child debraining via television.

What to do? Avoid fluoride toothpastes, drink only certified fluoride-free bottled, or better yet, distilled water, put filters on your showers (call 800-728-2288), and get busy starting a political action group...or joining one, if you've got one already. Oh yes, one more thing, if it's too much trouble for you to avoid fluoridated water, then please stay the hell off 20m. We have far too many addled brains on there already. And, one more thing, better start looking around for the nursing home of your choice for when Alzheimer's sets in and turns you into a veggie.

If you think I'm exaggerating, look it up in Vol. 17, #2 1995, *Neurotoxicology and Teratology*. Well, at least get the book I recommended in February. If you've thrown the issue out you can send $3 for my list of "books you're crazy if you don't read."

I got tired of spending 79¢ a gallon for distilled water and bought a small still from Damark ($200). Then I lower the surface tension so my body will better absorb it with Flanagan's Crystal Energy. Wetter water. I suppose I should become a distributor for that stuff. One teaspoon per gallon of water is all it takes. Eddie Albert is using about six times as much in his drinking water and swears by it.

Whither cold fusion?

1995 was one heck of a year for the cold fusion people. In addition to cold fusion conferences in Boston (MIT), Monaco, Bombay, Tokyo, Sochi (Russia) and Molise (Italy), there were some demonstrations of cold fusion cells as a fusion conference at the University of Illinois, and another at Power Gen in Anaheim, where the heads of power companies saw their worst fears confirmed.

Cold fusion first popped up in 1989 when Professors Pons and Fleischmann of the University of Utah announced that when they passed an electric current through a lithium and deuterium electrolyte with a palladium cathode, after a while the cell started generating a whole lot more heat, by thousands of times, than could be accounted for by any known chemical reaction.

The media jumped on this new energy source with headlines.

The chemists and physicists were skeptical. Cold fusion? Ridiculous! Impossible. So they went to their labs, pulled out an old chunk of palladium from a drawer, and tried it out. Nothing happened, so they called in the reporters for their 15-minutes in the news. The fact that most of the universities checking out the cold fusion reaction had millions to lose if they lost funding for their hot fusion work I'm sure didn't affect their diligence one whit.

The head of the DOE published a book on "Cold Fusion, The Fiasco of the Century."

Meanwhile several laboratories did confirm the P&F reaction, but they found it required a very good grade of palladium and days to weeks for the excess heat reaction to start.

Word of the successes leaked out, despite the refusal of any scientific journals to publish any submitted papers or the Patent Office to even look at patent applications. Perpetual motion rubbish.

So the work on cold fusion progressed mainly in Japan as new hydrogen energy, and in Russia, India and Italy. Pons and Fleischmann were so angry over their humiliation that, when a branch of Toyota came along and offered to build them the laboratory of their dreams anywhere in the world, they ended up with a $25m lab on the French Riviera.

The reality

How real is the dream of a non-polluting new energy source that can provide power at less than 10% the cost of fossil fuels such as coal, oil and gasoline? And what will something like this do to the world economy?

One inventor, Dr. Patterson of Sarasota (FL) came up with a new approach to cold fusion. He made microspheres of plastic and then flash coated them with palladium in order to provide a maximum of surface area per unit volume. With hundreds of these tiny spheres in a lithium solution in plain water instead of the more expensive deuterium used by P&F, in April, at the 5th International Cold Fusion Conference in Monaco, his cell was demonstrated producing up to 600% more heat out than the energy required to trigger the reaction.

By October at a University of Illinois fusion conference his demonstration was putting out over 100 watts of heat with only one watt of drive. Scientists from 35 countries checked the instrumentation.

In December, at the Power Gen conference in Anaheim, a scaled-up version of the cell was demonstrated, just in case there were any questions about whether a larger version would work. This cell generated 1,300 watts of heat with but 1.4 watts of drive! This created quite a storm and resulted in a flurry of power company subscriptions to my *Cold Fusion* magazine.

Indeed, there seem to be no major problems to scaling the system up for megawatts of power or down to power wrist-watches. But we're still just barely out of year one when it comes to practical cold fusion power.

There is a need for much more research. Experimenters will be testing various metals such as nickel, rhodium, rubidium, platinum and combinations of them. They'll be testing various electrolytes, temperatures, pressures, excitation voltages, frequencies, RF assistance at the hydrogen and other frequencies, vibration at various frequencies and so on. We're in a scientific no-man's land here, so most of the work is empirical.

The theory

In fact I've been getting more and more papers submitted for publication in *Cold Fusion* proposing explanations for why the cold fusion reaction is turning out so much anomalous heat. The physics establishment hates the whole business since it's "impossible." At first they said that everyone claiming to have produced excess heat had made stupid experimental errors. "They're all mistaken." Why? Because the current standard model for the atom doesn't permit it.

When I first got involved in all this I didn't know anything more about muons and leptons than you probably do. What I did know was that here was another new technology that needed some support to bring it from a laboratory curiosity into a new industry. So two years ago I started reading and asking endless dumb questions, just as I had done back in 1975 when the first microcomputer kit was announced. And in 1983 when the compact disc was introduced. And when I got interested in ham teletype in 1949, and then repeaters in 1969.

Hey, I haven't done anything you couldn't have done, if you'd made the effort. It has little to do with brains, and if you are using that excuse I suggest you invite yourself to a local Mensa meeting and find out how little big brains do for most people. No, it's just plain hard work. That's the prescription Edison gave when they asked him about genius. 99% perspiration and 1% inspiration.

So I've read a pile of books, but coming at the field from a new direction, I haven't been so totally tied down by the work of past geniuses, who may or may not have been right. There's something to be said for starting dumb. Since I have no ego tied up in needing to be right in this new field, I shrugged and proposed my model for the atom. In formulating my model I drew upon a new model for how the solar system evolved as proposed by Eric Lerner. This also explains to formation of galaxies, and even, on the next level of abstraction, why we have super-galaxies. I also drew on the 1908 book by Besant and Leadbeater on their clairvoyant visions of atoms.

Can I explain how an atom is made up in simple language? Of course.

We know from blowing atoms apart in super-colliders that they're made up of quarks. And quarks are made up of sub-quarks. And we know that all of this stuff has spin. Now, please picture a sub-quark made up of a small ball of energy. It probably looks something like a ball of yarn, with the energy that makes it up spinning around the ball, rising to the top, zipping down the middle in a tight vortex, out the bottom, and around maybe seven times again and fwoop down the vortex again.

These little energy balls are held together by the suction of the energy in the vortex. But this also tends to attract nearby balls of energy.

Think of quarks being made up of strings of these little spinning balls, which in turn make a larger spinning quark.

You may not have delved into physics far enough to know that scientists have had no good explanation for inertia. Nor have they had a reasonable explanation for why we have gravity. Einstein proposed gravity as being the result of the deformation of the space-time continuum. Sure.

Now let's suppose we have a box full of spinning gyroscopes. If we try to push the box, the gyroscopes are going to resist, right? And once you start them moving they're going to tend to continue to move in the same direction. Voilà, you have inertia.

The collective attraction of these energy balls for one another we sense as gravity.

I've proposed this theory in my *Cold Fusion* editorials, fully expecting to be dumped

on for being so dumb. A couple of scientists have called, naming the energy balls "Green Balls." Well, at least they didn't suggest Green's Big Balls. But though the readership of the publication includes some of the world's top physicists, no one has dumped on me yet. They probably will.

Why cold fusion?

Not satisfied with going way out on a limb with my proposed solutions for inertia and gravity, I've been reading more books, looking for clues to what's happening to produce all that heat. The power of the vortices in my little energy balls could explain how the dread Coulomb barrier is overcome. This is a force that keeps two protons apart.

In my January editorial I had a section on alchemy today, recommending the book, "The Philosopher's Stone." Well, the more I thought about it, the more likely it seemed to me that what was happening in the cold fusion cells was hydrogen changing to helium, though lab tests have confirmed that not enough helium is produced to explain all of the heat generated. Okay, perhaps the lithium in the electrolyte is combining with two hydrogens to form beryllium and/or with four hydrogens to form boron. And why not also check and see if the palladium is combining with two hydrogens to form silver? It won't hurt to check for sodium too, which might be the result of lithium combining with one oxygen. Or palladium with oxygen to produce antimony. The universities of Illinois and Missouri are checking some used cell microspheres with mass spectrometers to see if there are signs of element transmutation. I'll be surprised and disappointed if they don't find I'm right on what's happening.

Each of these proposed transmutations would tend to release heat, easily explaining the excess heat generated by the reaction.

The media

The first sign of serious media attention to the recent cold fusion developments was the airing of a segment on Dr. Patterson on "Good Morning America." This was followed that evening on "Nightline" by a full half hour devoted to the Patterson cell. The main critic of cold fusion has been Prof. Huezinga of the University of Rochester, who put his scientific reputation on the line by publishing a book, "Cold Fusion, the Fiasco of the Century." The poor professor, faced with Dr. Patterson's success, sat there with his eyes closed or blinking most of the time, apparently wanting to hide, and stuttering about there being no detected radioactive products, so it couldn't be fusion. No, since it was impossible, he hadn't bothered to look into it. Figures.

Cover Photos

If you're handy with a camera, show me what you can do—let's see some interesting photos I might be able to use on the cover. Sure, antennas can be fascinating, and a hamshack with a zillion dollars worth of equipment can make us envious, so I'm not discouraging the tried and true. But that just tends to make *73* like the other ham rags, and we're *not*.

As old Uncle Don used to say, "Let's put on our thinking caps." You remember Uncle Don, right? Every night for years on the Mutual Network at 6 pm. Of course, he's better known today for something else he said. Anyway, let's see what you can

Debunking Some Myths

Continued from page 59

9. Impedance mismatches cause power reflections on the feedline. Assuming a loss-less feedline, a) all reflected power will be returned to and radiated by the antenna, and b) all received signal power will be returned to the receiver. However, if a mismatch between the receiver and feedline exists, the reflected signal power will be returned and re-radiated by the antenna.

10. High SWR in a coaxial transmission line does not create RF currents to flow on the surface of the outer braid. When the currents are of equal amplitude, even open-wire feedline will not radiate due to high SWR. The currents must remain balanced.

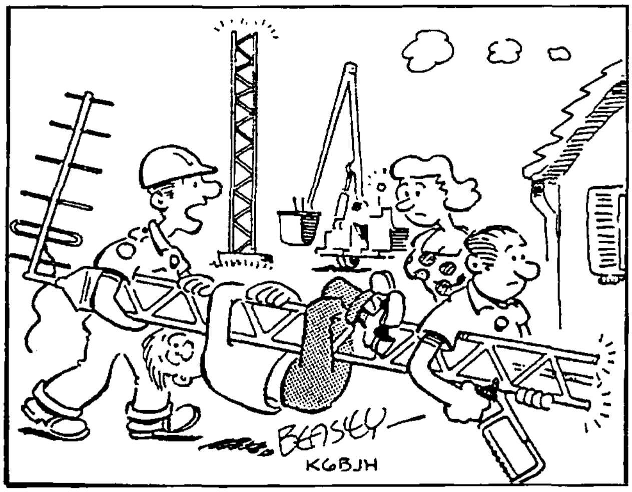
11. Loading coils (used to shorten antennas) provide the necessary inductive reactance to cancel the capacitive reactance. It is very easy, and very wrong, to believe that the coil is replacing the missing "length."

12. Using a balun transformer to transform (change) impedances to a transmitting antenna is often desirable. However, the balun must be operated within its power rating, or the ferrite core material may become saturated. A heated balun is the result of wasted, non-radiated RF energy.

13. A big antenna does not radiate more power than a small antenna. However, large antennas do confine the radiation into a much more directional pattern than a small antenna. The larger antennas, due to the concentrated directional capability, also receive or capture more signal than the smaller antennas.

14. When using a frequency meter to find the resonant frequency of an antenna, the meter should be connected at the antenna. Connecting the meter after a length of feedline measures the resonant frequency of the combination.

While it is fun to discuss antenna systems, we all need to make a conscious effort not to propagate falsehood—one operator was overheard telling another radio operator that his transmission line must have a 1:1 SWR because it lay perfectly flat on the ground and didn't have any bumps in it. I think he may have been equating impedance bumps to speed bumps!



Toon 3: *Sorry about the tower, ma'am—we couldn't pry your husband loose.*

Edison—The Fabulous Drone

by J.L. Elkhorne

Was Edison really the great genius schoolbooks tell us he was? Or was he simply very diligent and hardworking?

The Great Man confided that he tried "everything" while working on inventions. When 10,000 experiments with a storage battery went down to failure, he said: "I have not failed. I have just found 10,000 ways that won't work."

He argued with Nikola Tesla, the brilliant Serbian engineer and scientist, telling him that AC electricity was a "waste of effort and money."

"Looks like a bunch of Chinese laundry markings," he remarked of his hired mathematicians' worksheets.

He said: "Genius is one percent inspiration and 99 per cent perspiration."

Most people think Thomas Alva Edison was perhaps the world's greatest inventor. But in comparison to his contemporaries, he was an inveterate fiddler, who scorned abstract work to tinker about with one failure after another.

Tesla observed of Edison's work methods: "If Edison had a needle to find in a haystack, he would proceed at once with the diligence of the bee to examine straw after straw until he found the object of his search." Tesla said further: "I was a sorry witness of such doings, knowing that a little theory and calculation would have saved him ninety per cent of his labor." Edison plodded along, content to improve on existing ideas, insistent on hand work over brain work, and often completely blind to the uses of his own great and original work. Of his first phonograph, he said: "Maybe we could use it for some sort of telephone repeater."

In later years he said of its first successful test: "I was never so taken aback in all my life. Everybody was astonished. *I was always afraid of things that worked the first time.*"

Even after patent rights were issued to manufacturers, Edison claimed it was "just a fad, and would be completely forgotten in five years." As late as 1925 he would not concede that electronic phonographs were superior and maintained that T.A. Edison, Inc. would make an improved mechanical phonograph for long playing records.

Also in 1925 he noted that the 'radio craze' would soon pass. "The present radio...is certainly a lemon. It will in time cure the dealer of any desire to handle any kind of radio." He also insisted that the public would not stand still for having to listen to the programming the broadcasters provided.

In 1926, though very hard of hearing, Edison tested an electronic phonograph perfected by Bertil Hauffman, a Swedish engineer, at the Edison Laboratory. Edison found the reproduction 'distorted and terrible' and ordered that Hauffman be fired. Son Theodore, director of the works, arranged for Hauffman to work thereafter in a part of the laboratory that Edison was not likely to visit.

Edison once said that he enjoyed his deafness because it permitted him to concentrate. Though his progressive deafness made him almost stone deaf in elder years, one wonders if the affliction also allowed him to ignore criticism in earlier times.

Another facet of the Edison myth is the famous story of his sleeping only four hours a night. John J. O'Neill reports in his biography of Tesla: "It was a regular practice with Edison to sit down in his laboratory and doze off into a three-hour nap about twice a day."

Edison was strangely averse to theoretical work himself; as a thinker, he was second rate—as an administrator, second to none. The 'Wizard of Menlo Park' hired batteries of mathematicians and physicists, laughed at their theoretical approach, but utilized their results.

When the young genius Nikola Tesla came to this country, he had a letter of introduction to Thomas Edison, four cents in his pockets, and the key to alternating current electricity—today's housepower—locked in his mind. Edison offered him a meager eighteen dollars a week, providing he never spoke of AC.

Tesla proved himself an able engineer and inventor, regularly submitting improvements for Edison equipment. When Tesla suggested research toward improved dynamo manufacture, Edison told him: "There's fifty thousand dollars for you in it—if it works." Inside the week, Tesla presented the design. When he finally had to ask about the money, Edison grinned and said: "I guess you just don't understand our Yankee humor."

Tesla quit. Some months later, he had interested investors in his ideas for AC, constructed working models, and applied for a patent. The U.S. Patent Office responded that the ideas contained in the original patent application were so far-reaching that no less than forty would cover them!

George Westinghouse, industrialist and inventor himself, offered Tesla one million dollars for the rights and the Westinghouse Electric Company was formed. This was prologue to the biggest battle of the 19th century: a technological war in which Thomas Alva Edison was the prime antagonist.

Edison had recently spent two million dollars with his DC system in New York City. The financial threat posed by Westinghouse and Tesla could not be ignored. Although Edison had said AC was "a waste of effort and money," he found his system impractical to produce voltages higher than 220, as the dynamo commutators heated badly. Too, line losses necessitated either large, expensive conductors or power stations spaced every mile or so.

DC power left the generating plant at about 120 volts. the users closest to the plant had the brightest lights, sometimes so much so that bulbs burned out frequently. Conversely. those at the end of the line had light hardly better than candlepower. because of the voltage drop along the line. With Tesla's AC system. alternating current could be transmitted equally to home or factory. with negligible power loss in the lines.

Edison wrote: "Just as certain as death Westinghouse will kill a customer within six months after he puts in a system of any size...it will never be free from danger."

Westinghouse argued that of thirty deaths by electricity in 'recent' years. sixteen were from 'safe' DC circuits. and none from Westinghouse equipment. During one period Edison lost about a workman a month with 'safe' direct current and almost burned down the fashionable Vanderbilt home on Fifth Ave. A fire started when metallic-threaded draperies shorted out the wiring which had been placed behind it. Mrs. Vanderbilt returned home to find a confusion of firemen. assistants and Edison himself. Learning that there was a generating plant in her cellar. she became 'hysterical' and declared she could not live over a boiler. "We had to take the whole thing out," Edison ruefully remarked.

To sway public opinion in the "battle of the currents," Edison and Charles Batchellor—ironically the man who gave Tesla the letter of introduction to Edison—demonstrated the horrible danger of alternating currents by electrocuting cats and dogs. using a one kilovolt generator. They paid eager schoolboys twenty-five cents a head for all the animals they could deliver. It is said that the house pet population around West Orange stood in danger of being annihilated. During one of these edifying illustrations for guests. Batchellor lost his hold on the dog he was about to electrify and himself received the shock. As he put it later: "The sensation was of an immense rough file thrust through the quivering fibers of the body."

After this. Edison published an article saying in part: "I have not failed to seek practical demonstration...I have taken life—not human life—in the belief that the end justifies the means." Yet in the final battle of this strange war. Edison seemingly reversed his opinions and requested permission to install AC equipment in upstate New York. Westinghouse hastily agreed.

It might be said that the news of the installation came as a shock to Westinghouse—it was the first electric chair. The New York State Legislature had adopted a statute in 1888 to provide for capital punishment by electrocution. H. P. Brown. a former research expert for Edison. supervised the installation of the 'hot squat' for the Edison General Electric Company.

On August 6. 1890. convicted murderer William Kemmler was to be executed. The first attempt at death by legal electrocution was a failure. as the electric force was too weak. The unfortunate man was led away. After quick modifications to the chair, "The miserable work was perforce done again, resulting in a spectacle much worse than hanging."

A frantic Westinghouse recouped by obtaining the contract to provide power for the Columbian Exposition of 1893. Tesla had his own exhibit there. where he mystified fairgoers with his scientific marvels. The climax of the many performances was the passing of one million volts of AC through his body to melt a copper plate. It was not high voltage that killed. he maintained. but the destructive heating of high currents. High amperage DC could and did kill as readily as AC. While working up his demonstrations. he discovered the medical principle of diathermy.

The public was won over to AC and in 1895. Tesla harnessed Niagara Falls. His powerhouse was completed. providing AC for Buffalo. New York. twenty-two miles away. It was hailed as the greatest engineering achievement in the world to that date.

In 1896. a mysterious cigar-shaped airship was seen by hundreds of people over San Francisco Bay. and subsequently was reported in successive eastward sightings. A New York *Herald* reporter obtained this statement from Edison. who disclaimed any knowledge of the never-identified craft: "I prefer to devote my time to objects of commercial value. At best airships would only be toys." A few years later. he was congratulating Alberto Santos-Dumont for inventing powered flight. not recognizing the achievement of the Wright brothers.

The Edison Effect—the expulsion of particles from a heated filament—grew from experiments with the light bulb. Edison found that bulb life was shortened by the deposit of carbon from the filament. He sketched in his notebook the first two-element vacuum tube as a solution to the problem, having found that current would flow into the second element. This forerunner of today's diode was patented but never used, and the patent lapsed.

With the diode, his discovery of the 'etheric force' and a subsequent patent of wireless transmission based on electrostatic induction. he had in his grasp the elements of a complete radio system several years before Hertz demonstrated the existence of radio waves. Later in life, he said that it was a pity he had not seen any connection between them.

His first major invention. the carbon button microphone. is virtually the same today; it improved an existing idea. the Bell device. Edison came, as it were, into a technological vacuum, purifying existing and imperfect concepts, and applying much of the random electrical science accumulated over fifty years. He did enough that he could well say in later years his productivity brought him "awards by the quart." He patented over 1.100 inventions and gained a vast reputation while his more brilliant and less understood contemporaries are all but forgotten.

George Westinghouse himself patented over 400 inventions in his lifetime and founded 60 companies.

Charles Proteus Steinmetz, whom Edison liked "because he never spoke of mathematics to me," published the law of hysteresis when he was only 27. went on to produce artificial lightning and delve into higher mysteries. He is little known today.

Nikola Tesla. besides giving the world AC. demonstrated radio control before the turn of the century, developed a working system of broadcast power, lighted his laboratories with wireless fluorescent lights in 1889, and had over 700 patents to his credit when he died in 1943. Yet he is the forgotten man of electrical science.

Edison. the Great Man, reigns supreme.

SPECIAL EVENTS

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the April issue, we should receive it by January 31. Provide a clear, concise summary of the essential details about your Special Event.

APR 6

AIKEN, SC The Aiken Contest Club will sponsor the 2nd Annual Aiken Hamfest and Computer Show at Aiken County Jaycee Fairgrounds. US Hwy. 1 North. 4 mi. South of I-20. Doors open Sat. at 9 AM. Box DX, Genoa CO 80818-0119.* 73

Barter 'n' Buy

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The 73 Flea Market, Barter 'n' Buy, costs you peanuts (almost)--comes to 35 cents a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham sure It still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to: *73 Magazine*, Barter 'n' Buy, 70 Rt. 202N, Peterborough NH 03458 and get set for the phone calls. The deadline for the June 1996 classified ad section is April 12, 1996.

Payson AZ 85541

April is expected to provide some very interesting conditions for DXers. The Poorest days (P) are expected to be the 8th and 21st–22nd. The Best days (G) are expected to be the 1st, 4th–5th, and 25th–27th. The 10th–13th, 16th–17th, and 29th are expected to provide only Fair (F) conditions, while the remaining days should be trending, as shown on the chart. Sunspot activity may also be increasing with the imminent onset of Cycle 23.

Intermittent daytime thunderstorms will provide the occasional QRN to wipe out weak signals just when you need confirmation of a report or call sign! However, you'll note that Good, Fair, Fair-to-Good, and Good-to-Fair conditions should be present on 23 days, leaving only 7 days to worry about. You should be able to score big-time DX in April, particularly in view of the overall seasonal improvement in solar flux levels. Good luck!

'here 10m is shown, also check 12m. Where 15m is shown, check 17m o. Where 20m is shown, be sure to look at 17 as well. Always check the unds above and below the indicated bands for possible openings to the eas shown. Remember that DX is where you find it, and not always 'iere it is predicted to be.

10–12m

Occasional trans-equatorial F-2 layer openings during daylight hours, with 12 meters to show greater signal strengths.

15–17m

Circuits from the northern hemisphere to Africa and South America should open on *good* days, and daytime short-skip openings will also be present on *good* days. Performance of these bands will be sporadic, but on some days will sparkle.

20m

This will be your most consistent band of choice for DX opportunities from sunrise until after sunset. Expect DX from northern to southern hemispheres with decent signal strengths on most days, and short-skip openings to 2,000 miles as well.

30–40m

DX from just before sunset until shortly after sunrise will provide enjoyment on the *good* days. However, be aware of seasonal QRN interfering with weak signals. Signals peak to the east before midnight and peak to the west before dawn. Daytime short-skip will be good out to 1,000 miles or so.

80 and 160m

DX during hours of darkness will be available, but not as prevalent as during the winter months. QRN may become a problem for weak signal reception. Some daylight short-skip on 80 will be present, but none at all on 160. 73

UPDATES

Sunrayce

Oops!

We hope you enjoyed "Satellites, Weather Imagery, and Sunrayce '95" by James R. Buchanan K8WPI. We do have a couple of things to clear up—the specter mentioned on page 10 was Rod *Serling*, not Sterling; (##25) should have been (>25); and the 2 wavelengths at which the author tailgated the tractor-trailer should actually have been .2; quite a difference in anxiety ratio there!

IMPORTANT SAFETY NOTICE

Alert reader Calvin Hashi N6SSW sends this warning of possible Fire Hazard:

In "Simple Mobile Protection" published in January's *73* the author states "...the relay I used is one commonly used in mobile two-way radio installations." He adds "I've seen similar relays for sale at auto accessory shops as horn-relay replacements."

DO NOT USE HORN-RELAY REPLACEMENTS!

In Calvin's own words, "A horn-relay is designed for an intermittent (not continuous) duty-cycle. A few years ago, I tried to use a horn-relay for continuous duty, only to have it overheat (the relay actually started smoking). A much better choice (for about $5.00) would be to use a 20–amp continuous-duty relay that is used for auxiliary automotive lamps (like fog lights) that you might find in a four-wheel drive accessory shop. *The important thing is to use a relay that has a continuous current rating of 20 amps or more.*

We join Calvin N6SSW in hoping no one's car has caught fire because of a horn-relay!

do in the way of some creative ideas for the *73* covers. Surprise me.

When you're planning the shot I hope you'll remember that the cover is vertically polarized, in case you've missed noticing it. And don't forget to leave some unimportant (picturewise) space along the top for the magazine logo and space for a few article teasers somewhere.

Yes, of course, despite the incredible fame your amazingly creative photo will achieve, I will still manage to eke out some reward money. And just to make sure your fellow hams will be in proper awe of your genius, I'll include your photo and credit on the table of contents page.

One note: the family dog with earphones, sitting at your ham rig and captioned "CW Hound," will not the mustard cut. Another note: 35mm, if you use a tripod, can hack it, but you'll get much better results with a 6x7 cm camera. 73

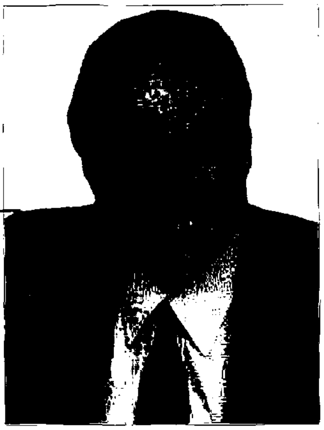
NEVER SAY DIE



Wayne Green W2NSD/1

Well, here we go with another of Wayne's editorials...starting off with a call for you to get elected to your state legislature—to help save amateur radio, if nothing else. Then I start teaching Making Money 101. I push (again) for you to give outstanding hams recognition before they die of poor nutrition and dehydration like the rest of us. I'll bring you up to date on the exciting recent cold fusion developments, plus some ideas on biological transmutation. Stuff like that.

I really should stop taking showers! That's when all of my better ideas hit. And this morning's brainstorm is a corker. It's a way we can turn our hobby into a national movement.

I've been fussing at you for years about getting youngsters back into the hobby, endlessly griping about how our beloved ARRL, then controlled by millionaire Mort Kahn W2KR, wiped out 95% of the school radio clubs 30 years ago, destroying the infrastructure which had been feeding hams into our hobby for the 17 years after World War II. Indeed, school radio clubs provided 80% of our newcomers up until 1964, and we had a steady 11% growth per year. Just thought I'd remind my Alzheimer's readers.

How would you like to help to not just keep amateur radio alive for the next generation, but to help make it grow again? How would you, at the same time, like to help a few million youngsters have a better chance at high-paying high-tech jobs? We hams, more than most people, know how important it is to understand the fundamentals of electronics and communications.

The electronic genie has been let out of the bottle and no amount of protectionism is going to stop the changes it's making in the world. Cellular phones, faxes, a new generation of personal communicators, computer networks, beepers, and so on have changed how business is run. Low cost communications and transportation has put workers almost anywhere in the world in direct competition for many of our jobs.

Our manufacturing plants are in competition with those in Korea and Pakistan, where their wages are not only a fraction of ours, but their educational systems are vastly better, and their degree of automation is enough to scare the hell out of any American manufacturer. I've written about a Korean factory I visited that turns out color TV sets by the millions. It is so totally automated that their labor per set is under 15 minutes, including packing and shipping!

More than ever before, it's either work smart or you don't work. Computers and communications are thinning the administrative ranks as well as the factory work forces. Most machines are now numerically controlled, with robots replacing workers without demanding vacations, sick pay, health insurance, unemployment insurance, coffee breaks, smoking breaks, or overtime.

I hope it is no news flash for you, but our worse-than-Third-World school system is *not* preparing our kids to cope with technology. And that's where *you* come in.

Yes, I know, the country is being run by politicians whose foresight is limited to their next reelection campaign. But that's not only a problem, it's one hell of an opportunity. And, with few exceptions (I hope), our politicians are being controlled by their major campaign donors. And that ain't us. The whole existence of amateur radio today depends on our being invisible instead of on what we're contributing to society.

Okay, here we are with around 700,000 licensed hams. That's a pretty good group to work with, but only if we can get 'em all headed in the same direction.

The plan

One of the biggest favors we amateurs could do for our states, our country, and our hobby, would be to get an eight-year course in electronics, communications, and computers into every grade school in the country. And I'll tell you exactly how we can do it, if you're game.

The key is to start locally and work upward. It doesn't cost a lot to run for the state legislature. What kind of an impact could we have if only 1% of the hams could get elected to state legislatures? That's 7,000. I don't think there are that many state legislators. Here in New Hampshire we have the largest state legislature in the country, with 400 representatives. Now that's local representation! But then New Hampshire is such a small state that I know all of my senators and representatives personally. And the governor. The president of the University of New Hampshire has been a good friend for over 35 years. And so on.

The main promise you can make to the voters is that you are going to work to improve our school system. By getting our kids a better education we'll help them make better incomes and be more able to compete with workers anywhere in the world. An eight-year course (grades 5-12) in technology isn't going to solve every educational problem, but it'll probably be better than any other single change we could make. If you can get the ball rolling in your state, we'll see this becoming a national movement. This isn't something that can be organized by Washington bureaucrats. This has to start locally.

Of course, one of the r oblems in teaching electronics is the speed of change. By the time a new textbook can be produced and accepted it's two or three generations of chips behind. Teaching kids 1990 technology in 1996 is stupid. The simple and logical answer to that is a monthly magazine for each of the eight grades. It would cover the material for the month, have a special encyclopedic section on one specific technology, and columns on high-tech hobbies such as ham radio, computer hacking, science fairs, and so on. The idea would be not only to teach the kids, but to get them personally involved so they would enjoy learning and go out of their way to learn as much as they could.

But, you probably argue, if you are a true-blue negative thinker, a magazine like that would cost around $25 a year per student and that might be prohibitive for many low income families. So how about allowing advertising to pay the freight? Would you really be upset if Sears, Nike, et al helped make a world-class education possible for your kids? Or grandkids?

I'll bet there would be a bunch of electronic and other science kits advertised too. Heck, with enough advertising, each issue could include a small parts kit or a CD-ROM. We might be able to wean the next generation away from Nintendo and TV.

A course like this would get a lot of kids interested in science, bringing us many more scientists and engineers. If we're going to get back our consumer electronics industries from Japan we're going to need 'em. Of course, we're only losing a few tens of billions of dollars in revenues, so who cares, right?

And I have a sneaky plan for making it possible for colleges to run tuition-free, without government or even alumni subsidization. And they'd graduate kids in three years instead of four, learning maybe double or triple what today's grads do. As a legislator you'll be in a position

LETTERS

From the Ham Shack

Eleanor Schlan K6LGZ. You asked about good public speakers. I heard Jerry Freeman K9AAH, who just retired from the FCC. He gave a *fantastic* talk to our ham group.

You're right! I've known Jerry for 30 years or so, and he's got a wealth of great FCC-ham stories to draw on...Wayne.

Guy A Matzinger KB7PNQ. The hobby of amateur radio is showing some classic symptoms of hypersensitivity to suggestions that code testing speeds should be eliminated or reduced to not more than 5 wpm. The latest drumbeat from pro-code advocates who adamantly oppose the relaxation of Morse code tests is, "Standards will fall." Test speeds of 5, 13, and 20 wpm could be considered standard speeds for test purposes, but how does the day-to-day operation of anyone's station tie into these undefined standards? Even the FCC avoids defining their standards. Western Union had a minimum code speed (standard) for their telegraphy operators— so did the Armed Services. Amateur radio is not a private activity or a professional telegraphy service and those using CW should be able to operate at their own speed. Why, then, are 13 and 20 wpm code tests jammed down amateurs' throats?

Pro-code advocates expend enormous amounts of ego-driven energy with their self-centered views that those who cannot demonstrate "high speed code proficiency" should not be entitled to enjoy the hobby and, with bureaucratic pandering, they have put up legal barriers to limit participation. These rampant egos, with their lingering "standards" paranoia and their total disregard for technical advancements, make it impossible for mature amateurs to respect any organization that contends they represent amateur interests. Fearlessly soliciting meaningful feedback from the majority of amateurs, not just from those who have convinced themselves that limiting participation is a virtue, will drive improvements and, with rational collaboration, will create the future of the hobby. Political action will then achieve results that support the desires of the majority—perhaps in a manner similar to that which changed apartheid—with or without approval of hard-line opponents.

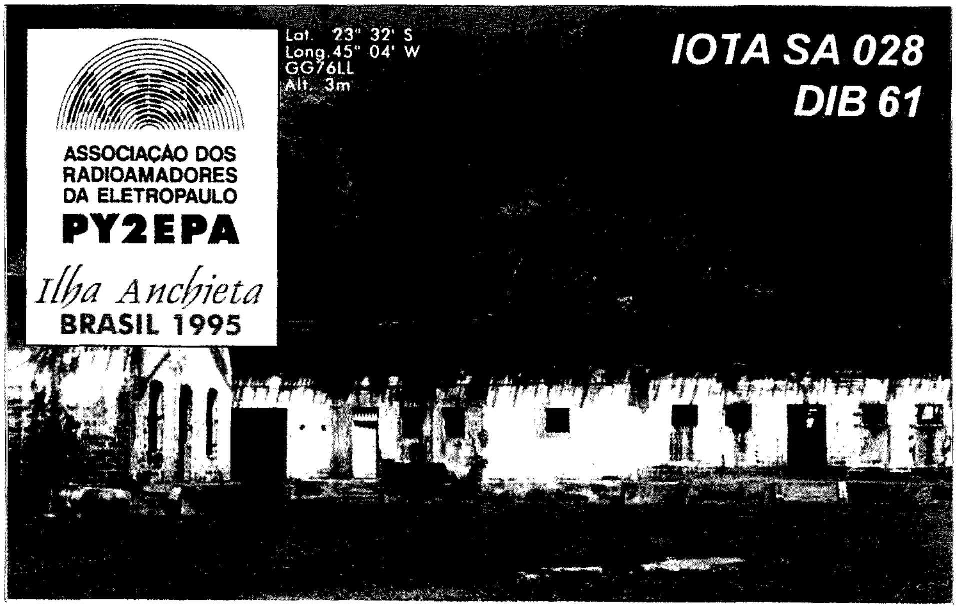
Radio spectrum is owned by the citizens of this country and both the use of that spectrum and amateur licenses are subsidized by taxpayers. Most counties charge amateurs annual licensing fees, but pro-code advocates contend that amateur operators are entitled to these "freebies" because of the "services" rendered to the community. This delusion is constantly being generated by those who want something for nothing. Occasionally some public service may be provided, but, as police from across the country have reported, cell phones are the preferred choice for emergency communications.

The constant babble that this is a technical hobby may have had some merit 60 years ago, but considering the "plug and play" technology of today's equipment, anyone who can read can assemble the necessary components to operate an amateur station. It is doubtful that 1% (7000+) of the amateur population constructs their own equipment or makes significant modifications to existing gear. The majority of amateurs are not even interested in how—technically speaking—their hardware achieves results. Continuing technological improvements can't be stopped, but improved operating could, and should, be provided to ensure an enjoyable hobby experience for the majority of amateurs.

Current testing practices no longer facilitate the society of amateur radio operators. Old ways may have been adequate years ago, but, to survive in the future, amateur radio must face the reality of today's communications technology and be responsive to the innovations and ingenuity that, even now, is evolving around the world. Recognizing the need to change is essential for any activity that wishes to avoid obsolescence—and just fading away.

Troublemaker...Wayne

Carlos Carneiro PY1CC. Here's the QSL that was sent to the stations who contacted ZW2EPA on Ilha Anchieta during a four-day DXpedition. It's a small island about five miles off the coast of São Paulo. It was once run by pirates, then by slave traders, next it was a prison, and now it's a park run by the Forrest Institute for tourists. The operators were PY2CL, PP5LL, PY2PA, PY2AH, PY2EVW, PY2FAR, and PU2NMA. The QSLs are handled by PY2YW. The best band was 15m, where almost 900 contacts were made. And almost 600 on 20m. Well, band conditions were poor. It's not a new country, but it was a new island for the Islands Of The Air (IOTA) and Brazilian Islands Awards (DIB).



Walter Rawle VE1AWS/W5. The article Crystal "Controlled Audio Generator" by J. Frank Brumbaugh KB4ZGC, Nov. 1995, issue 422, was very well done except for a significant flaw in the schematic diagram. C11, the output coupling for the Q3 emitter follower stage, is connected to the positive supply rail. The accompanying text indicates that the Q3 stage output is connected to the Q2 mixer stage. This error motivates an interesting question: Does the mixer work better with both signals applied to the base with the transistor driven into saturation, or does the mixer work better with one signal applied to the base and the other signal applied to the emitter with the transistor operating in its linear region? It would be beneficial to have the author reply on this item.

On a second topic, I would be interested in reading your opinion on what I refer to as the "high price" of ham radio equipment. Despite the avalanching price of RF components resulting from the upward swing in the commercial wireless industry, ham radio equipment prices remain at levels consistent with those five years ago. As an RF engineer working for a company involved in the commercial spread spectrum systems market, I

QRX . . .

Four Days In May — The QRP Event of 1996

QRP Amateur Radio Club, International (QRP-ARCI) proudly announces the first annual QRP Symposium to be held on Thursday, May 16 1995 - the first day of four festive days of 1996 Dayton Hamvention QRP activities. Mark your calendars and get your hotel reservations in early for this not-to-be missed QRP event of the year.

Conference presentations, meetings and workshops on everything you wanted to know about amateur radio QRP will all be part of this full day Thursday event to be held at the Days Inn Dayton South (513-847-8422). QRP-ARCI Symposium attendees will start their day with a wake-up coffee social and then plunge into a morning of multimedia QRP presentations by renowned QRPers and QRP equipment manufacturers. A short break for a catered lunch and some special QRP door prizes and then back to an afternoon of more exciting QRP technical presentations. And if that is not enough, then come join us for a Thursday evening of QRP break-out session tutorials. The 1996 QRP-ARCI Symposium will be the talk of the Dayton Hamvention.

QRP-ARCI continues the "Four Days in May" QRP extravaganza with nightly hospitality suite sessions, where QRP projects from around the world are displayed with a pride that only a QRPer could appreciate. "Four Days in May" QRP-ARCI week culminates with the annual QRP-ARCI Friday Night Banquet honoring QRP dignitaries for their service to the amateur radio community.

Registration for the QRP Symposium will be $30 if prepaid by May 1, 1996 and $35 if paid after that date or at the door. Please send your $30 (US check, money order) QRP Symposium Registration fee made out to Paulette Quick, N9OUH at the address below.

Paulette Quick, N9OUH, Registration Chairman (plquick@facstaff.wisc.edu): P.O. Box 145, Madison WI 53701-0145: (608) 263-9326 (work phone)

Happy Birthday 6 Meters

An important anniversary took place in March of 1996—it marked fifty years that US radio amateurs have been on 6 meters. This means that other than the WARC bands of 10, 18 and 24 MHz, 6 meters is one of the newer Amateur Radio bands. It remains as one of our most interesting ham bands and is seeing rapid growth in several areas of the world.

U.S. amateurs were first assigned the 6 meter band in March of 1946, when they were moved off the 5 meter (56MHz) band. This reallocation took place in order to accommodate a new block of VHF TV channels by the FCC. There was little commercial gear available at that time, so many hams on 6 meters homebrewed their own 6 meter gear. During the 1950s and 1960s, commercial gear that could be converted for 6 meter, AM operation was manufactured. Six meter AM was thought of as a good local communication mode for line-of-sight work. In addition, it was used as part of the Civil Defense emergency network by hams involved in public service. Six meters was particularly popular with the Technician Class hams and this led to the label "Technician's band." From L'Anse Creuse Amateur Radio Club newsletter.

Computers vs. Automobiles

Here's a quote from Robert Cringley, "InfoWorld", "If the automobile had followed the same development as the computer, a Rolls-Royce would today cost $100, get a million miles per gallon, and explode once a year killing everyone inside."

HamVention Forum News

The forums at the 1996 Dayton HamVention will continue the tradition of offering more information than you could ever absorb in three short days, but you're up to the challenge, right?

On Friday there will be a special presentation on the role amateur radio played in the aftermath of the Oklahoma City bombing, along with presentations on AMSAT, TAPR Digital Radio, Antennas, Using Ham Radio in the Classroom, County Hunters, and the Electrical Safety Demo.

On Saturday, things get really busy because several forums from Friday and Sunday have been switched to allow improvement in the facilities. Some of you may have experienced the limitations of Room 7 during the last few years. You'll be pleased to know that Room 7 has been eliminated. Arrangements have been made for three forum rooms at the Meadowdale High School, which is located just a half mile from HARA. MHS is where the alternative activities are held, along with the license exams, and is regularly served by free buses. This year, there are seven forums scheduled at MHS on Saturday only, and bus coverage has been beefed up to assure that those who want to attend the forums at MHS will have the quickest trip that we can provide, both coming and going. The forums at MHS include: Combined QRP, Media and Ham Radio, Firebirds, Operating Techniques for New Hams, International Hungarian ARC, OSSBN, and Logging Programs. The alternate activities, including a luncheon, and the license exams will also be at MHS on Saturday.

Saturday has always been the big day for forums at HamVention, and it may take some planning to get to all of the ones that interest you. Forums at HARA include: DX, Contesting, MARS, Amplitude Modulation, YLRL, Amateur Radio and the Internet, Weather Satellites, Gerltol Net, SSTV, ATV, ARES, Youth in Amateur Radio, PACTOR, Direction Finding, VHF/UHF/Microwave, Digital Digest, AMSAT, Tech Talks, and the Electrical Safety Demonstration.

Then on Sunday the choices include: FCC, ARRL, Amateur Radio and the Law, Amateur Radio Repeater Operation, Mobile Radio Installation Tips, 10-10 Electrical Safety Demo.

There is so much to take in just from the forums you might be tempted to skip the vendors and the flea market! *From the RF-Carrier, DARA.*

JY1: Strong on MidEast Peace

On the international scene, Jordan's King Hussein JY1, is in the news once again. His Majesty was in Washington in March, where he joined the U.S.-led battle to prevent a wave of terrorist bombings in Israel from destroying chances for peace in the Middle East. In a meeting on Thursday, March 14th, with President Bill Clinton, the King said the bombings, which have killed 57 people, were the work of a small group acting against an overwhelming majority of people in the Middle East who are seeking a lasting peace.

According to several newspaper reports, King Hussein's powerful words helped to strengthen a United States-led drive to isolate the militants behind the bombing campaign and keep the Middle East peace process alive.

While JY1 has condemned the bombings previously, his presence at the White House alongside President Clinton gives a much higher profile to his own anti-terror stand.

Vanity, Vanity...

If you are wondering why the vanity callsign program is still on hold, look to some of your fellow hams for the answer. Several are still petitioning the FCC for last-minute changes in the program. Those petitions, coupled with a mandate from Congress to implement the Telecommunications Rewrite Act, have put vanity calls on hold at least until mid-year.

Still awaiting FCC action are Petitions for Reconsideration filed last fall by Charnelle H. Summers W4IJE; David B. Popkin W2CC; Robert Nelson, on behalf of the Hill Country Amateur Radio Club; and Christine M. Gill, on behalf of the Southern California Repeater and Remote Base Association.

As noted, it appears as if the FCC will not even begin to look at any of these petitions until early this summer. How long after that it will take to dispose of them is not known. And there is always the possibility that more Petitions for Reconsideration could arrive. By law, each must be addressed.

Even worse, some of the current crop of petitioners might take their cause further if the commission does not give them a decision favorable to a given position. This means appeals before the full Commission and maybe even taking the matter into federal court, if they have the money and the desire to do so.

Meantime, the FCC vanity callsign application Form 610V is now available, but the FCC will not accept completed forms until the appropriate filing gates are opened.

Build the Bioelectrifier

Heal yourself and take a poke at the medical establishment at the same time!

Thomas M. Miller WA8YKN
314 South 9th Street
Richmond IN 47374

One of the first things a new amateur learns is that electricity and biology are not very compatible. A brush with the AC line can be a painful experience, and accidental contact with the high-voltage supply of a large transmitting tube can be fatal. Because of this early training, occasionally reinforced by an unpleasant accidental jolt, it might surprise some hams that tiny electrical currents can be beneficial to the human body.

For some time, doctors have known that passing a small current through a broken bone will cause it to heal faster. Damaged tendons and nerves also seem to respond to this treatment. Exactly why this works is not known, although a doctor once explained to me that it seemed to focus the body's attention on the area.

Recently, doctors at the Albert Einstein College of Medicine reported discovering that passing a current of only 50 microamps through the blood can prevent certain viruses, notably the HIV virus, from replicating. The current became even more effective when the polarity was reversed several times a second. The implications are enormous.

Unfortunately, there has been very little interest in this phenomenon by the medical community. Those of us who read Wayne Green's editorials have become aware of a simple device which introduces a small electrical current through the legs by placing electrodes on the ankles. Since the arteries in the legs are large, and the blood has less electrical resistance than the surrounding tissue, this technique results in most of the current flowing through the blood. This is an ideal approach for amateur experimentation, since it is totally external, and the required voltage and current levels are so tiny as to pose no danger. I decided to design such a device, using a simple printed circuit board, and easily obtained parts, so that it could be duplicated by other amateurs.

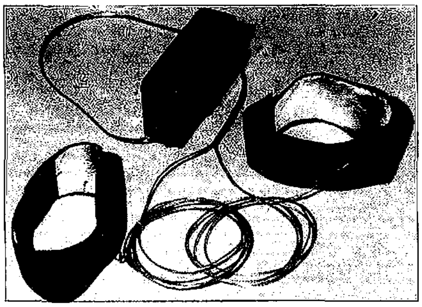

Photo A. The Bioelectrifier with belt clip and ankle electrodes.

At this point, let me state that I make no medical claims for this device. To paraphrase a famous Chief Medical Officer, I'm an engineer, not a doctor. Since very few doctors are electronics experts, there are many who would love to research the possibilities of this approach to eliminating vires in the blood, but are unable to build the needed experimental device. They need your help.

So I present this circuit for those wishing to help doctors experiment in an unknown field, and also as an interesting study in design and construction.

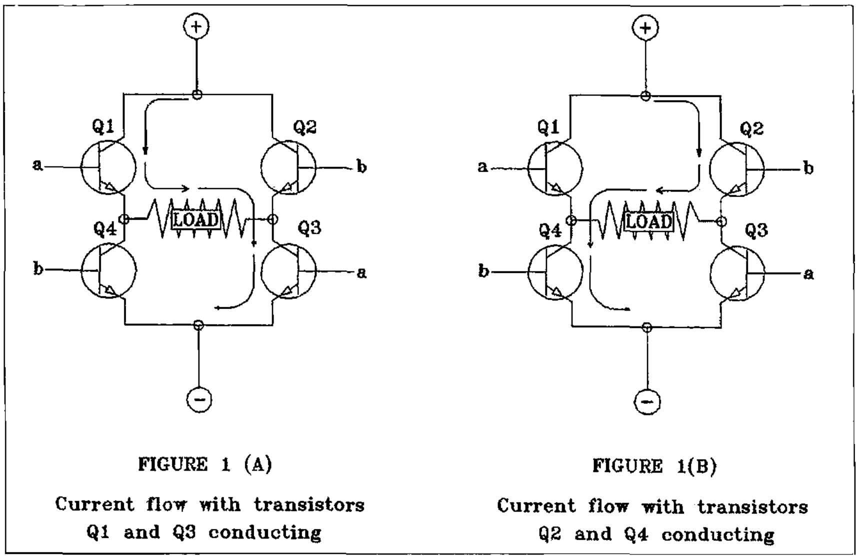

Fig. 1. Four transistors are used to reverse the current flow by energizing them in pairs.

Designing a Bioelectrifier

Before attempting to design any device, it's a good idea to make a list of goals. In this case, it's a simple list:

(1) The device should produce a current flow of 50 microamps from one ankle to the other. Experimentation has shown that this requires 30 to 35 volts.

(2) It must be capable of reversing the current flow several times per second. This rate should be adjustable.

(3) It must be all solid-state—no DPDT relays clacking away, eating up the batteries.

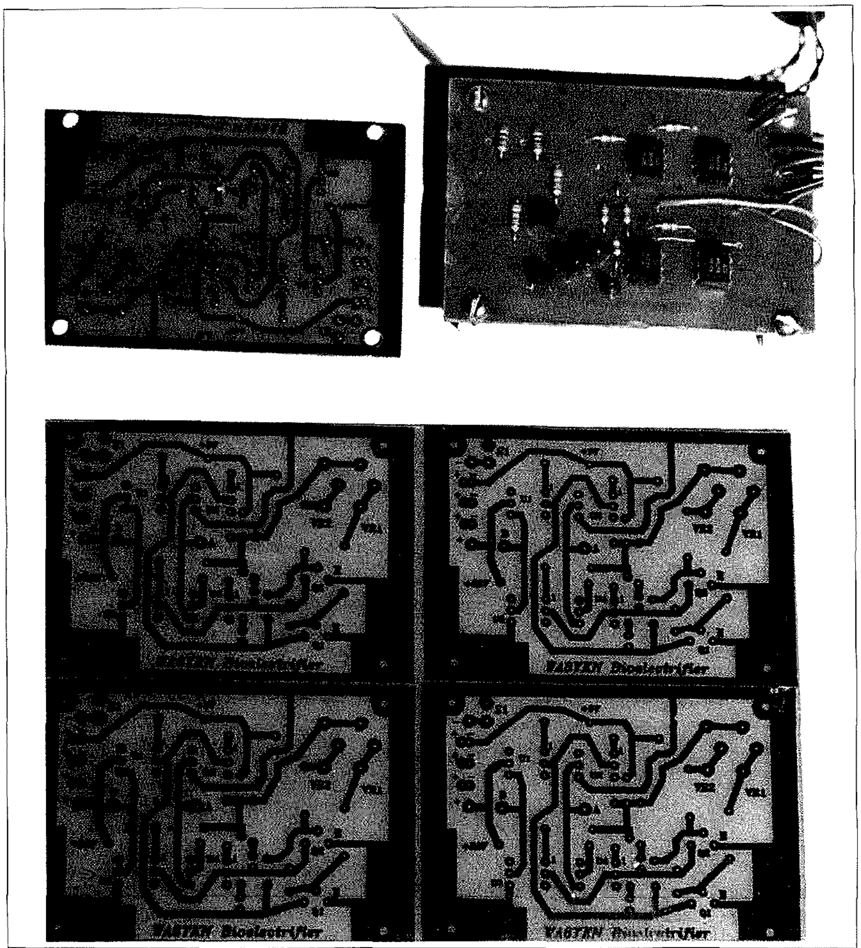

Photo B. Four circuit boards are etched on a single piece of copperclad and are cut apart after drilling.

(4) It must be small, light, and easy to carry. The ideal form would look like a pocket pager.

(5) It must have a low current drain for long life from small batteries.

(6) It must be as simple and inexpensive as possible, so that it may be easily reproduced.

This last goal is one of the most important in designing any device or circuit. It is, in fact, Occam's Razor, a corollary which states that when there are many ways to solve a problem, the best solution is the simplest one.

At first glance, it would be tempting to use logic chips, or perhaps a 555 timer and a flip-flop to get a variable timebase with an equal on-off ratio. However, this direction leads to a regulated power supply, high current drain, and a complex circuit. Also, logic chips will not switch 35 volts without an additional driver stage. Remember rule number six... the simplest way!

Maybe we'd be better off starting from the other end. Reversing polarity requires the solid-state equivalent of the DPDT relay. As it turns out, there is just such a circuit commonly used to drive and reverse DC motors. It uses four transistors in an "H" configuration, the load being in the center (see Fig. 1). When transistors 1 and 3 conduct, the current flows in one direction, while energizing transistors 2 and 4 reverse the flow. Most small switching transistors will stand up to our requirement of 35 volts at 50 microamps, but here we run into a new problem. For each direction, two transistors are in series, with the load in the middle. This creates a difficult bias arrangement to drive both transistor bases equally. Fortunately, there is a neat solution—the optocoupler. This invaluable device contains an LED and a phototransistor in one package. Energizing the LED produces light, which causes the phototransistor to conduct. No base voltage is required, therefore there are no bias requirements. Optocouplers are usually used to drive another device, but our requirements are so small that we can use them as output transistors.

The cheapest optoisolators cost less than a dollar and will withstand over 30 volts with current ratings in the hundreds of milliamps. For a few cents more, optocouplers are available that will withstand 80 volts or more.

With four optocouplers in the output of our device, all that remains is to alternately drive them in pairs. The simplest circuit to accomplish this is the multivibrator—nothing more than two general-purpose transistors, two resistors, and two capacitors. Voltage is not at all critical, and since we will be connecting batteries in series to get 35 volts, we can tap off at the 9 volt point to power the circuit. While we're at it, adding two more resistors and two tiny LEDs will give a visible indication of circuit operation and warn us when the battery goes dead.

Varying the frequency of a multivibrator requires that two resistors be varied

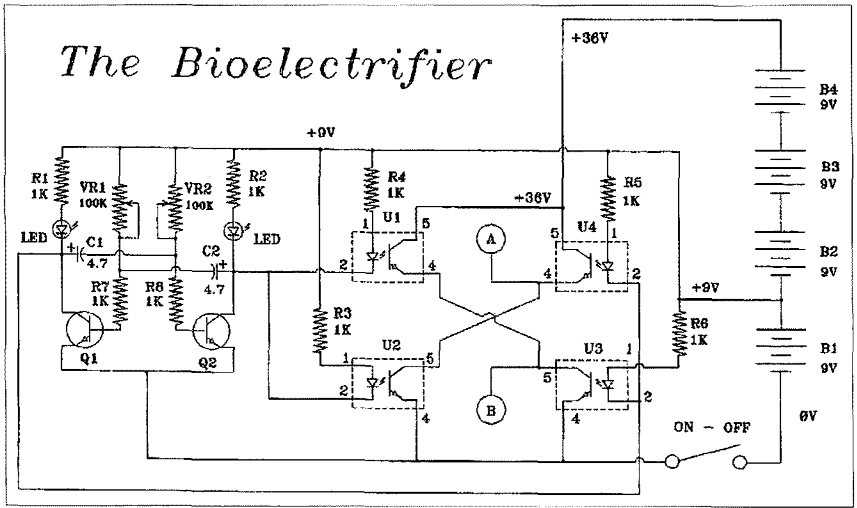

Fig. 2. Schematic diagram of the Bioelectrifier.

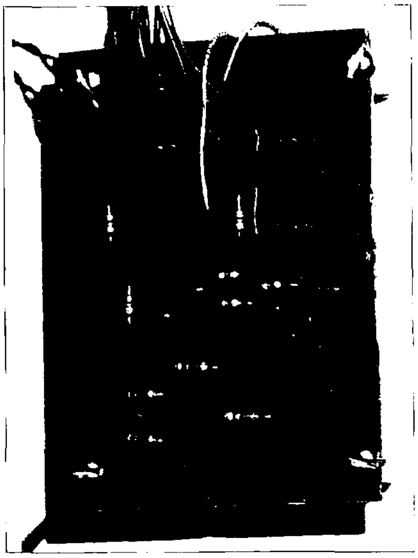

Photo C. The Bioelectrifier – component side of the board.

together...no big deal. Two-gang potentiometers are ideal for this. In fact, our design goals do not specify that an equal duty cycle is required, or even desired. Two trim pots will give independent adjustment of the two states if this is needed. A fixed resistor in series with each pot will establish a maximum frequency limit, preventing the circuit from dropping out of oscillation when the pot is adjusted all the way.

We now have the basis of a simple, practical design: four optocouplers, two transistors, one dual pot, two capacitors, two LEDs, and eight resistors, all of the same value! The schematic diagram is shown in **Fig. 2.** Of course, we will have to add a box, switch, and batteries, and some sort of electrodes. We also need a name. Since we are experimenting in bioelectrics, let's call it the Bioelectrifier!

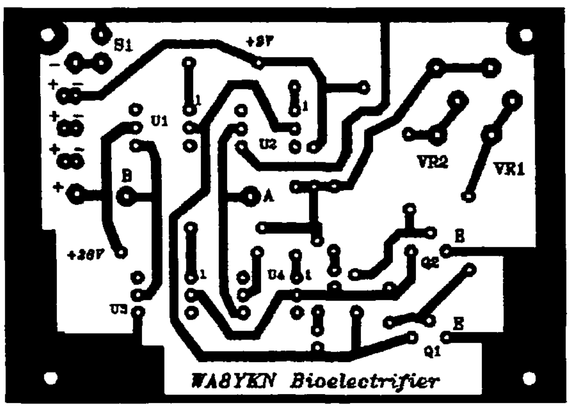

Fig. 3. The circuit board pattern, shown actual size.

The printed circuit board

When designing a printed circuit board for this type of project, a compromise must be made between size and ease of construction. The board should be single-sided with as few jumpers as possible, and there should be enough room for 1/4 watt resistors, in case the smaller 1/8 watt are not available. The final design is shown in **Fig. 3.**

In my work, I design and build a lot of prototype circuits, and I've settled on an easy technique for circuit board fabrication. I use a Computer Aided Design (CAD) program to create the actual pattern, and then use the computer to generate a mirror image. If the board is small, as in this case, I will then copy this mirrored pattern to get the maximum number of circuits from a standard positive pre-sensitized copperclad board. This mirrored array is shown in **Fig. 4.** After printing this pattern, I copy it with a standard copy machine and inspect the copy for places where the toner is less than pure black. These areas, if any, are touched up with a felt-tip marker. When I've got a pattern that will give a good, pure black copy, I run two or three copies to warm up the drum, then make a final copy on clear Mylar, sold in office supply stores for making overhead projector displays. It may be necessary to set the copy machine one step darker than normal, since machines tend to vary in how well they work with Mylar. This copy can be used as a positive for printing the circuit board.

Using a standard (4.5" by 6.5") pre-sensitized board, place the Mylar sheet with the circuit board pattern *toner-side down* on top of the board. (The writing should be correct—not reversed!) Place a piece of glass over the Mylar to hold it in contact with the board, and expose it for three and a half to four minutes using an Ultra Violet sunlamp 12 inches above the board. Be sure to protect your eyes during the exposure!

After the board is exposed, dunk it in the developer until all the copper between the traces is shiny and clean; this usually takes around two minutes, but you really can't overdo it. Rinse the board with cold water, and it's ready to etch.

I etch my boards with ferric chloride solution in a tall, thin plastic tank that allows the board to stand up vertically. The use of an aquarium heater and air pump will cut the etching time in half. Do *not* get the etching solution on anything made of metal—it will corrode badly. It also stains everything, so wear rubber gloves and be careful!

After etching, clean the etch resist from the board, polish with steel wool, and drill the holes. The individual patterns can be cut from the board using a bandsaw, jigsaw, or even by hand with a hacksaw if that's all you have. You now have not one, but four circuit boards ready for construction.

Building the Bioelectrifier

Fig. 5 shows the parts layout for the Bioelectrifier. Be sure to install the optocouplers correctly. Also, the very small LEDs often do not have a flat spot to indicate the cathode, but instead have one lead shorter than the other. Check before cutting the leads! The *long* lead connects to the dropping resistor.

There are two ways that this circuit can be built. For experimentation, the device can be mounted in a larger box, potentiometers used to vary the frequency and current, and perhaps even a microammeter to monitor the current. However, I've discovered that it's not always wise to give a device with many controls to a non-technical person, especially if changing any of the adjustments would nullify the experiment. Also, we want a pocket-sized device, or one that can be clipped to the belt. Once the operating parameters are established, the resistance of the potentiometers can be measured and the pots replaced with fixed resistors (I used 68K). This makes a much smaller package possible, with only a single on/off switch and two tiny LEDs on the outside. I built one in a 2 7/16" by 5 1/16" plastic box (Radio Shack 270-233) and mounted the switch and LEDs in the end. Four 9 volt batteries would not fit in this box, but one 9 volt and two 12 volt "N" batteries will fit with no problem, and produce 33 volts. Radio Shack sells 12 volt alkaline "N" batteries in a package of two, (23-154) and "N" battery holders (270-405).

I made a belt clip from a strip of steel banding material and glued it to the back. I also glued a two-pole terminal strip to the end of the box to connect the electrode leads, although a plug and jack would be fine. I used what I had on hand.

Electrodes for the prototype were simply strips of aluminum foil, folded to form two strips several layers thick, 2 inches wide and 12 inches long. Wrapped around each ankle, the foil was held in place by rolling the socks up over it. Later, a better electrode was made by gluing aluminum foil to strips of cloth-backed vinyl upholstery material, with hook-and-loop fastener material glued to the ends.

In either case, connect two 36-inch lengths of hookup wire to the Bioelectrifier's output terminals, and solder a paper clip to the other end of each wire. Slip one paper clip over each electrode, clip the Bioelectrifier to the patient's belt, and your doctor is ready to go.

OK, it's done. Now what?

Even if your doctor doesn't know anyone with the HIV virus, there are many experiments he can try with the Bioelectrifier. If it works on the HIV virus, what about others, such as those responsible for herpes, Epstein-Barr, colds, and flu? Will a few minutes a day actually *prevent* colds and flu? What effect will different frequencies have? The long-term benefits can only be determined by experimenting and recording the data.

It is interesting to note that all animal life on earth has evolved in the magnetic field of the planet. Blood, being mostly water and containing salts and iron, must generate a tiny voltage as it moves through this field. Is this voltage necessary for good health, and can it be disrupted by exposure to much more intense 60 Hz electromagnetic fields?

I've often wondered, as we think about manned missions to other planets, if we will one day discover that we cannot live for a great length of time without the Earth's magnetic field. So far, only a few people have ever left the planet, and only for a short time. These astronauts, however, have found that after a few days in space, the immune system starts to shut down! No one has yet found a good explanation for this. Perhaps a small application of bioelectrics is in order!

One interesting result reported by Wayne Green was that when his friend Beck used a similar device for two hours a day instead of the usual 20 minutes, just to see if there might be any harmful effects, he started losing weight! The weight loss continued until he reached his normal weight, then stopped. Since, as Wayne has repeatedly noted, many hams appear to be "eleven months pregnant," this could be the biggest thing since FM! Perhaps this device will open new fields of communication. Just adjust the frequency to match the 7 Hz resonant frequency of the Earth and tune your brainwaves to Dr. Jung's Universal Consciousness!

All kidding aside, there have been enough results from experiments to date to warrant serious study, and, as usual, mainstream science will continue to ignore it, while sucking up government funds for expensive and ineffective research. But breaking new ground is the amateur's forte. We have the technical skills and the manpower. Keep in mind that *every* new field is pioneered by

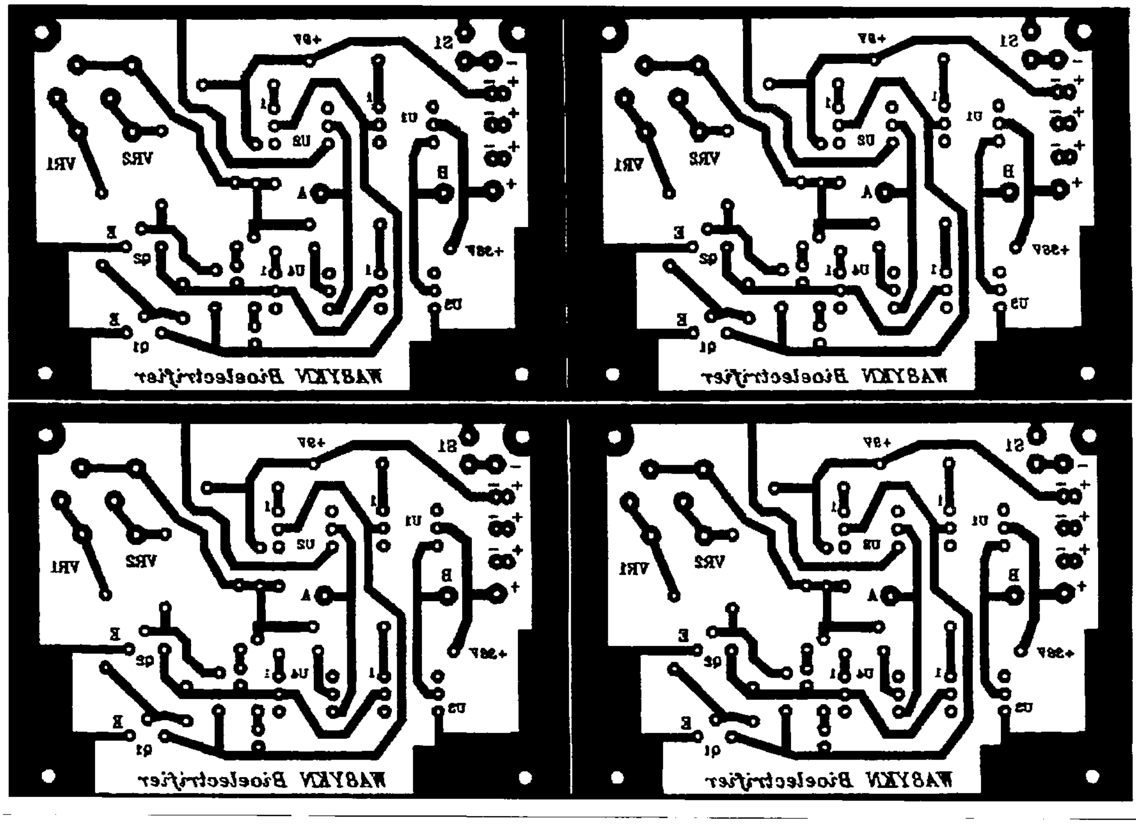

Fig. 4. Make your own "positive" by copying this mirrored pattern onto clear Mylar. Shown actual size.

NEVER SAY DIE

Continued from page 4

to help force your state university, with the professors kicking and screaming in protest, into the 21st century.

Self interest

It's about time you got involved in politics instead of griping about family values, the deficit, crime, drugs, welfare, and so on. If we can get our kids learning about electronics and other high-tech fields, we may even be able to help keep some kids from being suckered into dropping out of school and going into the crime or drug business. This will be good for everyone, including you and your family.

For my part, I can easily turn out the needed magazine. I've put out big magazines before, and I suspect this one, with a circulation of 20 million or so, would probably run several hundred pages a month, with eight editions, one for each of the eight grades. No problem, though I'd probably have to get a couple more Macintoshes for production. And I'd draw on you for the articles, encyclopedia of electronics series, and so on. The material has to be fun to read, as well as simple to understand. Right up the alley of several good ham writers.

Will we be seeing a million-ham day at Dayton? Why not? We might have to move

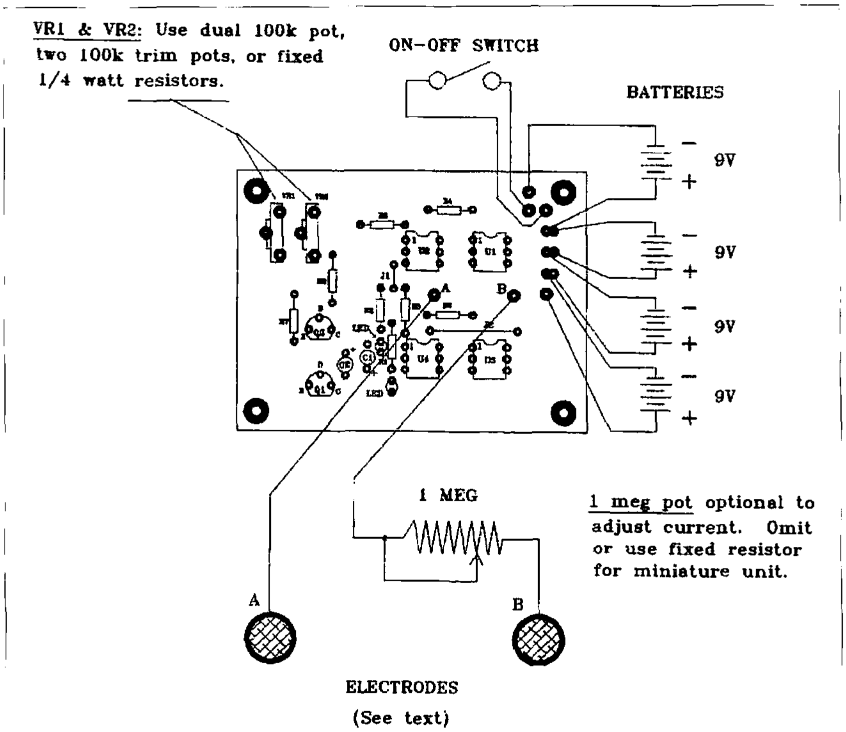

Fig. 5. Component side of the board, showing the component locations and connections.

amateurs—since the professionals do not yet exist!

One final caveat... *do not* build Bioelectrifiers and sell them as medical devices! This will surely bring unwanted attention from the wrong people. After all, these days even the U.S. Department of Health and Human Services has a S.W.A.T. team! So build it, work with a doctor to experiment, and make sure to keep careful records. Don't even give one away to someone who wants to try it but doesn't have the skills to build it, unless you have no qualms about opening yourself to almost unlimited liability. Remember, the FDA and several other government agencies have unlimited funds to persecute you, and they love nothing better than the slightest excuse to appear to be working. The last thing you need is to get the attention of the bureaucrats, who would probably protect the interests of the pharmaceutical cartels by outlawing bioelectricity, requiring us all to wear grounding straps on our behinds.

I would be interested in hearing about your results with the Bioelectrifier. Those with Internet access can send me E-mail at THOMIL@delphi.com.

A Note From El Supremo: *I highly recommend the inclusion of the 1 meg pot in series with the electrodes so that the current can be kept comfortable for the user. I adjust it so I can feel a throb, but no pain. Also, as I mentioned in my editorial, I find it easier to put the electrodes on one wrist, where there are two arteries, and keep them in place with an elastic strap. There is still a need to blast hiding critters out of the lymph glands with a coil in series with a flash gun. Then the Bioelectrifier will take care of 'em!*

I like Bob Beck's latest approach, labeling the device as a "plant growth stimulator." A commercial model, which I've been using to stimulate the degrowth of any possible viruses, bacteria, fungi, or parasites in my own aging body, is clearly marked as an experimental plant growth stimulator, not to be used on humans. I also liked Bob's sheaf of before and after lab reports of people who had had the HIV virus, which I looked over at the Global Sciences Congress in Tampa a few weeks ago (which you didn't bother to attend).

I would make a lot more noise about this except for two things. Make that three. First, I'm not an MD, so the medical industry will probably have no interest in anything I have to offer. Second, efforts to try and bring down the costs of medical treatments could easily trigger an FDA attack and prison. Ask anyone who's read about what happened to Wilhelm Reich, Raymond Rife, Gaston Naessens, and hundreds of others. Third, I'd sure like to have some people come out and say that they were dying of AIDS and a blood purifier saved their lives. Or even a few of the people to whom I've sent circuits to call or write and say they used it with success. I've never had anyone write and say they had tried it and it didn't work. I've had phone calls saying it did, but no written proof.

So, is this one of the biggest medical discoveries of the century and Bob Beck in line for a Nobel Prize? ignoring it, as the NIH and WHO have, isn't the answer. Trying to stamp it out, the FDA's approach, isn't either.

Can it really wipe out parasites and viruses in your or your pet's blood, or is it only good for stimulating your hemp growth?

Belcher Islands DXpedition

Take off to the Great White North.

Winston Seeney VE3WFS
224 Cornwallis Court
Oshawa, Ontario L1H 8E8 Canada

If my wife could have seen me at that moment, she would have written me off as a madman. What teacher in his right mind would begin his summer vacation standing with a friend atop the airport garage at Sanikiluaq? The arctic wind whipped our pant legs like flags. The coax and guy ropes danced to their own senseless rhythm. From moment to moment, the precipitation switched back and forth from rain to snow to rain... seemingly unable to decide which torment we most deserved. John Harden VE3VGI shouted through chattering teeth, "What a contrast! When we put this thing up four days ago, it was 82 degrees and we were wearing shorts."

Al Griffin, our pilot, watched from the warmth of the nearby pre-fab airport. His face mirrored his concern; which one of us would be blown over the edge? Was our struggle worth it all? Al hadn't read John's sense of determination well. John is an athlete, and for years he has boxed, run marathons, and driven his body to the limits of endurance in cross-country ski races. For John, this marked the end of months of hard work. Our Belcher Islands DXpedition was in the books, another of a lengthy list of accomplishments in the story of a unique man.

"Thanks, guys. I'm a handicapped operator—you make it easy for me to travel the world."

It seemed like yesterday when John, Laird Solomon VE3LKS, and I sat in a Tim Horton's in Oshawa, on the eastern edge of Toronto, discussing a possible DXpedition. As I stirred my coffee, I quietly commented, "This is every ham's dream, but how many do it? If we say we will do it, we will."

The gauntlet was thrown. From that moment on, we agreed to a goal that had to be met. Unfortunately, the end came for Laird four months early when his wife, Connie, entered her final term of pregnancy. Laird had to withdraw from the team, but at that time, when doughnuts, coffee, and idle conversation came easily, we dared to dream.

Where would we go? Our trip had to be remote, yet affordable and attractive enough for both local and distant hams. If we were lucky, we would provide a first-time activation. At first, we thought of the High Arctic. Names like Ellesmere Island and Alert Bay rolled off our tongues, but when a local pilot suggested a fee of $10,000 to transport us and our gear to Calumet, a large community on Baffin Island, we decided to change our destination to a more affordable, southern location.

After much consideration, we decided upon Sanikiluaq, in the Belcher Islands of Hudson Bay. John discussed the problem with a friend who worked with him at General Motors. John's friend was a pilot and, although he liked the sound of the trip, he was unable to make it because his health failed. He passed us along to his brother, who was also a pilot, and who also liked the idea. We had the green light.

For our pilot, Allan Griffin, an air controller at Toronto's Lester B. Pearson International Airport, our trip to the Belchers fulfilled his long-held dream of flying to the north. His plane was a hardworking

Photo A. *Winston Seeney VE3WFS and John Harden VE3VGI*

little PL 30 Twin Comanche. It had been flown for years by Henry Shannon, traffic's voice in the sky for radio station CFRB, Toronto. Allan provided us with an affordable DX opportunity by sponsoring us with a return flight from Oshawa to Sanikiluaq for the cost of fuel.

Having overcome the transportation hurdle, we were faced with the problem of siting a station in an unfamiliar town. To save expenses, we decided to establish a base with tents and portable camping gear. We also decided to huddle as close to the airport as possible. With that in mind, we contacted Bob McLean, an airport employee at Sanikiluaq. We needed whatever support he could offer from the airport: electricity, toilet facilities, a refrigerator, and protection from bad weather. When we arrived at Sanikiluaq and learned that the airport wasn't very busy, we asked Bob if we could work from inside the building. Bob's response was a laid-back, "No problem, help yourselves, guys."

After arrival, John and I took a quick overview of the terrain around the airport. The airport and adjacent garage sat on a hill about 1,500 feet high and two miles outside of town. John, who had constructed and tested our rotating quad antenna, knew exactly how much space it required. The flat garage roof, some 30 feet off the ground, was ideal.

The skyline was magnificent. To the north, we could see the ice floes which had broken away from arctic glaciers and floated up to the island's shore. Below us, Sanikiluaq huddled around a small inland harbor. Surrounding us were hills and tundra. We set to work, snapping the telescopic sections of mast pipe in place. Then came the supporting guy wires, followed by the large triangle-shaped driver and reflector wires. After we had completed the familiar ritual of untangling wires, the structure was drawn tight.

Our next problem was feeding the coax into the room which served as our shack in the airport. We couldn't keep the outside door propped open because the temperatures dropped too low at night, and during the days the mosquitoes drifted off the tundra in raiding parties. John spotted three holes in the wall that were stuffed with packing and appeared to have been used at one time as an entrance for cable. As luck would have it, they were in a wall of the room that we had selected for our shack and, with Bob's OK, we reamed the caulking out and shoved in the coax. Within hours the radios were fired up. We made a few test contacts and our initial reports were solid. After dinner, VE8RAC was up and running.

Our station consisted of three rigs: John's Kenwood 440, my Kenwood TS 50, and our sponsor, Durham Radio Sales and Service's Alinco DX 70. It had been our plan to rotate around the rigs, with one man having time free for himself. Allan, our pilot, respectfully declined to man a station. "Sorry, guys, this is a break for me from work. I talk on a microphone for a living." John and I found ourselves caught in a situation we hadn't counted on. Allan had been good enough to fly us north for the cost of fuel. We felt that we couldn't leave him to wander alone for three days while we DXed, so we decided that we would keep one radio operating full-time and we would spell each other off. This would provide Allan with a companion. We would double-team our station whenever we had the chance. For much of the time, this was a sensible decision. It meant that we could adequately rest, and combine our trip with the opportunity to explore the area and to fish.

On the air

VE8RAC went on the air on the evening of June 29th. We moved onto the 20m IOTA frequency and were immediately swamped with calls. We were pumped up. To work the receiving end of a pile-up brought into play all the art and skill of a thousand hams I had heard over the five years that I been a ham. I came into the situation determined to give everyone a fair chance, although there were times that this wasn't possible. The Voice of Texas demanded to be heard by covering weaker signals. "Answer him. Get him out of the way," was our feeling. Unfortunately, he was usually replaced by another 10-gallon operation. I suspected, though, that for every one mega-station, there were a dozen average barefoot hams in the background who were waiting patiently for their opportunity. We were thankful for the many hams who expressed their appreciation for our efforts. "Thanks, guys. I'm a handicapped operator. You make it easy for me to travel the world."

Occasionally, I would stop and invite QRP stations to take a shot. When we were operating above 14,500, I would sometimes give Canadian stations a chance to take a break for it. The frustration of untangling dozens of interwoven callsigns was heightened by the carriers of stations tuning up on frequency.

It soon became apparent that our choice of islands was a good one. For three days we were a hot commodity. At times, we moved down onto the 40 and 20 meter subbands to shake off the large demand by American hams, and to make international and national contacts possible. The constraints of time defined our operating practices. One evening I called into the Sandbox Net on 7063 kcs and spoke to Stephen VE3DP in Thunder Bay. Stephen had a nice signal into the north. A few stations in southern Ontario and the Maritimes were workable. Most of the stations on the net were quite low. Although I am a Sandbox Net regular, I found myself in a dilemma — trying to decide whether I should devote two hours to having hams try to wring out a contact with me at the expense of the very real possibility of working a couple hundred hams elsewhere. DXpeditions exist for multiple contacts, so I had to move on. The log

Photo B. Main Street, Sanikiluaq

became a monster which had to be fed, and it had a huge appetite.

Exploring the island

During our off times, we explored Sanikiluaq. It's an Inuit town of some 400 people, a cluster of small bungalows sitting nakedly on blocks above the rock-strewn ground. Most of them had multicolored beasts of indeterminate but wild lineage chained outside. Those dogs eyed us from their perches on top of snowmobiles, umiaks, and packing crates. As we walked along the streets, miniature all-terrain vehicles bombed past in clouds of dust. Smiling Inuit men and women waved.

John tuned the boom box, which sat on a desktop in our makeshift shack, to the Inuit-language local radio station. "Listen to this," he said. I expected chanting, drums, and the cry of a people thousands of years old, weaving in and out of the night like northern lights. Instead of mystery and poetry, the shriek of an alternative rock band violated the northern night.

During my off times, Allan and I fished in the harbor. My catch was humble—a cod twice the size of my hand. The locals claimed that a Spanish fleet had beaten us to the punch. Allan drew in three grotesque fish with fins like fans, and bodies covered with knobs, spines, and bumps. I told Allan that he fished ugly and he laughed. The natives call that species Offish (ugly fish).

When we weren't fishing for DX contacts or casting into the harbor, we fished for soapstone carvings. We made our best contacts at the Northern Store. I suspect that the prices we paid, while modest by southern standards, were attractive enough to encourage the local artisans to sell to us instead of the local co-op. Bartering is part of the game.

All of the villagers speak Inuit, most speak some English, and English is the first language for the kids in school, so they made great interpreters. On our second day, a procession of all-terrain vehicles worked their way up to the airport from the village. Summer holiday had begun and with it came the annual exodus of the teachers to their homes in the south. We found ourselves explaining our presence over and over again to curious villagers and to the members of the southern white community who lived in the village hotel. These, for the most part, were

Durham Radio Sales & Service Inc.

tradesmen and workers who worked in isolation during the summer months. These "Northern Junkies" came from across Canada to work in the north for isolation pay, for months at a time, before returning to their families in the south for winter. During the evening, they lounged about the colorful Amatuk Hotel, watching videos and making small talk. For some, our station was a diversion, and they enjoyed the chance to talk to someone new.

On July 1st, Canada Day, during my break from the radio, I was drawn to the bank of a small stream which ran through the village. A large group of Inuit had gathered around someone shouting through a megaphone in their language. I worked my way through the crowd and watched a game in contest. A dozen or so people were eagerly scooping water from the stream and into large containers, using small water scoops. It appeared that they were seeing who could fill their containers the fastest. The crowd then spread out and fanned past me. They were bent and focused on the ground. I stopped a high school boy and asked him what everyone was looking for. He told me that hidden among the rocks was a soapstone carving of a ptarmigan, a northern bird.

Meanwhile, on the hill outside of town, the airwaves were alive. John was passionately working the Canada Day contest. Throughout the afternoon and into the night, we worked stations back and forth across Canada from Vancouver Island to Newfoundland, but the Yukon was silent. Does it still exist? Is there really a VY1 land?

Because we had a coveted RAC multiplier callsign, we didn't have to go searching for contacts. Avid contesters dug us out of the multitude of "CQ Canada Day, CQ Canada Day," calls with a frenzy. John and I expected to work 20 meters throughout the night. We reasoned that because it was daylight in the north for 20 hours a day, our station would be operable. We were surprised to discover that, although it was still light, propagation dropped off late in the day, much as it did in the south. On the second night, the band was quiet from 1:30 a.m. to about 5:30 a.m.

Since the antenna faced Europe, we operated off the side of the quad to the west and into the Pacific. We found ourselves following the rim of darkness, as it worked west across Europe to North America and across the Pacific. Because we never changed the direction the antenna faced, we were unable to make comparisons with the success we might have experienced had we moved it around.

On the second night, I worked Australia and New Zealand at 0600 UTC. An enthusiastic ham from the vicinity of Melbourne helped me coordinate several contacts Down Under. On many occasions, signals had what seemed to be arctic flutter. On the other hand, it might have been the natural echo effect created from receiving a delayed "around the globe" signal off the back of the quad. We also used a vertical antenna for the 10 through 40 meter bands. Since it lacked the gain, we used our quad antenna in its place.

The three days were punctuated with frequent surprises. There were conversations with hams we knew from previous conversations. On one occasion, we broke a pile-up into the Franz Josef Land DXpedition, high in the Arctic Circle, to the north of Russia.

Throughout the time we were in the north, John had arranged for personal contacts and messages to be relayed by Glenn VE3AEQ, a fellow member of the North Shore Radio Club — our home club. He passed personal traffic for us. Messages were given to our wives: Yes, we were eating well and we were cleaning our teeth before we went to bed; the usual stuff. In the wee hours when it grew quiet, I found myself yawning and fighting exhaustion, so I slept briefly.

At 5:30 a.m. I was back in action. We came to life in a hurry on Sunday afternoon, when John called me to the radio to listen. Someone in Europe had thrown our presence on the 20m IOTA frequency on the Internet. The radio erupted into a blast of unforgettable sound. Thousands of callsigns melded together into an uncontrollable wave of noise. It sounded like New Year's Eve in St. Peter's Square, Rome. Eager Europeans joined the carnival atmosphere by blowing whistles and clapping their hands enthusiastically. John's professional skill was amazing. He called upon three hams with superior stations to sort callsigns out of the alphabet soup. GM3ITN of Glasgow and Dewitt Jones W4BAA of Michigan fed John lists of stations he could work, but a feeding frenzy has a mind of its own. John was repeatedly overridden by impatient hams who demanded that their appetites be fed. Again and again, John announced, "Gentlemen, please await your turn." I marveled at John's patience. When he reached the moment of no return, he handed me the mike. "Take over; that's enough."

With that I told the mob that there was no bread in the bag. It was time to go home. I changed frequency and slid down into the 20 meter subband. The hams with operating smarts won the day. They searched us out and earned their IOTA 196 QSL cards by outthinking the mob. During this time, I worked a station from near Paris, France. His 3 1/2 watts earned a respectful 5 x 8 report. Nice contact!

While the Belchers were much in demand, we learned that we were the second DXpedition to the Belchers. During the three days, we worked Tony WT2O and Martin G3ZAY, both of whom had been part of a DXpedition here the previous year. They had operated from a tent station outside the hotel during their stay.

Eventually, the time came to pack up the station. With our soapstone carvings tucked away in our baggage, we boarded the Twin Comanche. As we rolled south through the valleys of clouds, each of us privately reflected. Would we do it again? You bet!

routinely design transmitters and receivers with parts costs below $30. From my experience, I can only conclude that ham radio equipment companies are enjoying high profit margins on their products. These profit margins are adversely affecting the growth of our hobby by establishing financial barriers that inhibit young people who wish to purchase their own equipment.

Thirdly, I must applaud your editorial comments on maintaining a healthy lifestyle. I became involved with body building about a year ago, for stress reduction purposes, and can now attest that a lifestyle based upon good eating habits and plenty of exercise, both aerobic and strength training, is essential for success in whatever you do. As a Canadian citizen who has recently moved to the U.S., I can provide many stories concerning the demise of the Canadian health care system which has resulted from abuse and irresponsible behavior. Those who advocate socialized medicine, be wary! When the state takes on the medical expenses of the population, the population must take on the responsibility for living a healthy lifestyle. If both parties do not actively fulfill their obligations under such a contract, failure will surely occur. Thanks for a great magazine.

Fiddlesticks. I've been hearing this high priced ham gear complaint ever since I got into ham radio. It's a bunch of baloney. You want to know about high prices? Check out commercial equipment. Sure, manufacturers have to get back some of their R&D costs as part of the price, but I know of no other high tech field where margins are as cutthroat as they are in amateur radio. If there was any money in manufacturing, we'd have more manufacturers. And without the huge Japanese ham market supporting us, we wouldn't have that great stuff form Icom, Yaesu, and Kenwood! An S-19 Sky Buddy receiver of 1938 cost $20. That's about $400 in today's dollarettes for a five-tube wide-as-a-barn drifting receiver. My SX-24 cast about $90 in 1938, which is around $1,800 today. It was a nice receiver, but not that nice. It drifted a lot too. ICs are consistently bringing ham gear prices down for us...Wayne

Mike Agsten WA8TXT. Many thanks to *73 Amateur Radio Today* for publishing "The SP-10 'Senior Spider' Transceiver" in the Jan. 1996 issue. Regrettably, the all-important Parts Overlay drawing, *Fig 3*, page 17, did not condense very well into the space available. Any reader desiring a larger, more legible copy need only send me an SASE requesting SP-10 POL. 73! Mike Agsten WA8TXT, 401 W. Bogart Rd., Sandusky OH 44870.

Glenn Farr N4AK. I just want to let you know how much I agree with your editorials about getting our youth involved in electronics and science via amateur radio. I hope to soon have time to get involved actively as an "Elmer." You're right on target in advocating removing the code requirement from the license exam. I am still fairly proficient in the code and enjoy many contacts during the year on CW. The code should become just one of the many facets of this great hobby like packet, DXing, rag-chewing on SSB, etc. In other words: If you like to operate CW that's just fine, but let's not kill the future of our hobby over something that has served its purpose. Obviously some of CW's main supporters haven't yet experienced the Internet to see what our hobby is competing with!

Here in Greenville, SC, as in many other areas of the country, restrictive covenants concerning antennas (and in particular amateur radio antennas) are to be found in all subdivisions. In order to accommodate my hobby and hopefully have some fellow hams as neighbors, I decided to develop my own subdivision (Nature's Watch subdivision) with a provision for amateur radio antennas. Month after month of reading "if you don't like it, get off your duff and do something about it" in your editorials influenced me to strike out in a new direction after spending 25 years with Philips Medical Systems selling and installing X-ray, CT and Magnetic Resonance Imaging systems. The first project therefore is Nature's Watch, a subdivision that will have only 23 home sites on 65 acres—adequate space to accommodate "a few good hams." Now how's that for a retirement project? Keep challenging us!

Wow, imagine the 24-hour a day TVI with 23 ham families on 65 acres! ...Wayne

William Thim Jr. N1QVQ. Mr. Green: I have sent in some items for the new "Ham to Ham" column, one of which dealt with special event stations using packet BBS addresses for contacts. I am a no-code ham at this time, limited to 6 meter SSB, 2m FM, and packet. The letter I received from Dave got my gray cells going. So far I have contacted and QSLed some two special event stations via packet because these are the only two I have found that give packet addresses from the sysops. I would like to know how many contacts were in "real time" vs. packet BBS. There is a ham in my area who runs a VHF/HF gateway. If more hams did this throughout the country special event stations could give packet addresses and the callsign of the local gateway for contacts. Not only would this help more people contact/celebrate the special event, but it would be *great* disaster training; i.e., how long would it take to get messages from a family in Minnesota to hurricane-ravaged Florida? Would it be possible to have different VHF/HF links between relatives in New England and disaster survivors of a quake in California? Good training exercises. Well, before I ramble on too much, let me tell you to keep up the good fight and congrats on your crew who keep our gray cells active.

Thanks, Wm., but at times it seems like we're fighting insurmountable odds...Wayne

Mark Jackson NØOWE, President SPARK (Sedalia/Pettis Amateur Radio Klub). There seem to be two schools of thought. The first, that there should be no code requirement because it is an outdated form of communications. The second, that no-code Techs should never have been permitted. Most no-coders, contrary to popular belief, fully understand why so many older hams feel the way they do. They had to struggle to learn code, many had to drive long distances to take their examinations, and if they failed, they had to start the process all over again. I can sympathize with this position, but this should not be used as an excuse to hold the hobby back. It is the same whether you are a ham or work for a large business. Many old-timers, in either case, will fight tooth and nail to hang on to the old ways and resist change as long as possible.

Instead of resisting change, why not take advantage of the opportunity to experiment with today's technology? One reason many Techs haven't upgraded is because they find so few benefits to using the code compared to the more modern communications modes available. Most of them have computers, so it's easy for them to set up their stations to send and receive Morse code at practically any speed. The computer does all the work. Most old-timers stay on HF and tell each other what type of rig they bought, what antenna they bought, what the weather is, and how loud their signal is. Sounds like a code test session!

Our local club had become one of Wayne's so-called stagnant clubs. Through reorganization and a lot of hard work we are making a comeback. During the last quarter of 1995 we held a Tech licensing class to help try and boost the hobby. We successfully licensed all but one individual. We started a new class in the first quarter of 1996 and will teach Tech, Tech-plus, and General. Several of our Techs will be taking the General or Tech-plus test. Most of the Techs I know value the wisdom and experience of our old-timers. I have learned a tremendous amount about the hobby from the older hams in our club. Maybe it's time for both sides to break down the barriers and take our hobby into the next century on the cutting edge.

So send a picture of your next graduating group...Wayne

Chuck Marlin AB4Y. Wayne, I just wanted to let you know that I've accepted an offer from a major telecommunications firm, and that my career success is due in no small part to you, and your decision to bring me on board at *73* magazine in the summer of 1982. The internship I served with *73* was one of the highlights of my life. Not only was it an excellent learning experience, but I enjoyed spending a beautiful

Editor's note: If you liked the 440 MHz J-Pole last month, here's how to build a version of it for 220 MHz.

Number 26 on your Feedback card

A 220 Super J-Pole Antenna

220—Use it or lose it. Here's a simple, inexpensive one-hour building project.

Marty Gammel KAØNAN
1703 Hewitt Ave. West
St. Paul MN 55104-1128

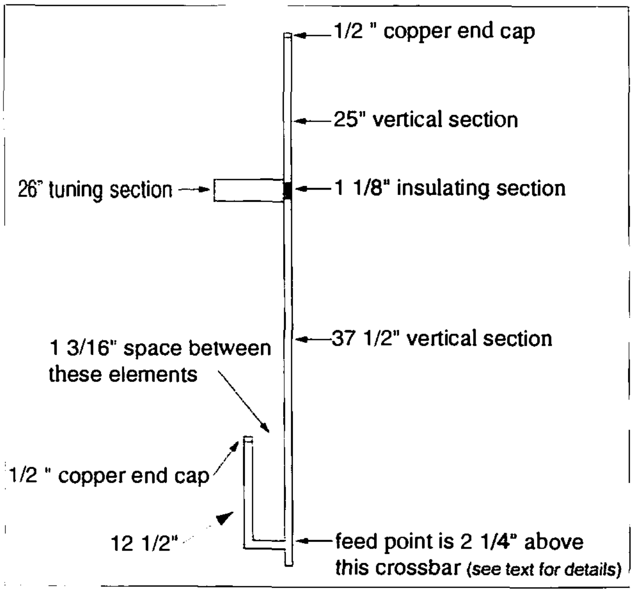
A local swap net helped me land an old Kenwood TH-31AT in good working condition. OK, now I needed an omnidirectional gain antenna. I found very few published 220 antenna projects in the ham magazines, and even fewer commercial gain antennas available. That was no problem, since I've made many J-poles over the last 14 years. The Super J-Pole has about the same gain as a well-known commercial brand antenna (about 5.5 dB), but without its poor low-angle radiation, which is more attuned to contacting aircraft than land stations. I knew my design would work with a broader bandwidth and lower SWR.

I made this antenna in less than an hour, once I had the materials on hand. Tuning it was easy; I spent less than 5 minutes finding the minimum SWR setting. My 220 Super J-pole has an SWR of less than 1.1:1 over the entire band, and with a little more fine tuning, I'm sure you can achieve an almost flat SWR.

Building it

Once you have all of the materials you can start this project. Cut all of the pieces to the lengths listed and clean the areas that will be soldered. I used solvent to clean all the copper surfaces (The secret to soldering copper tubing with a propane torch is to get the surfaces really clean). After the antenna is complete and soldered, the entire antenna should be polished clean with steel wool or a scrubbing pad.

Find the center of the 26-inch length of 3/16-inch tubing or wire, grasp both ends and loop the center around a broom handle or nearby pipe. Pull on both ends, and smooth out any kinks. It should now look like a very tall "U". The other bending of this section will be done just before tuning the antenna.



Now drill a hole about 3/16 of an inch from one end of the 37.5-inch piece of copper tubing, about halfway through the birch dowel, and 3/16 of an inch from the end of the 25-inch section of copper tubing, using the sheet metal heat shield as a spacer. Lay the parts out on your work table in the order they will fit together.

Dunk the pieces of 1/2-inch copper tubing right into the can of paste flux. Apply flux to the undrilled end of the 37.5-inch length of tubing, and slide an end of the "T" fitting onto it. Flux both ends of the base stub section and slide one end of the stub into the other end of the "T". Push the threaded 1/2-inch copper fitting onto the other end of the base stub.

Apply flux to both ends of the 1-1/8-inch crossbar piece. Insert one end into the side of the "T" and the other end into the 1/2-inch copper elbow. Finally, flux both ends of the 12.5-inch section of copper tubing, and put the other end cap on one end of the 12.5-inch section. Insert the other end of the 12.5-inch section into the open end of the copper elbow.

Measure the spacing between the 12.5-inch section and the 37.5-inch section. The 1-3/16-inch spacing must be equal at both the top and bottom of the 12.5-inch section. You may want to set a weight across these two sections to keep them in alignment when soldering.

Insert the 1/2-inch birch dowel into the top of the 37.5-inch section of copper tubing. Now is the time to bend the piece of thin sheet metal around the dowel to act as a heat shield during the soldering process.

Slide the 25-inch section of copper tubing onto the exposed end of the birch dowel, drill holes through the birch dowel, and install the 26-inch length of 3/16-inch tubing into the 37.5-inch and 25-inch vertical sections of the antenna. Finally, install a 1/2-inch copper end cap on top of the 25-inch section.

Soldering it

Check everything carefully before applying the propane torch. Then start at the bottom joint and work your way up, using the angle of the torch's flame to

heat the copper tubing without overheating. Discoloration will indicate overheating. The end caps are the last items to be soldered. Then wait for the rest of the joints to cool down.

After all soldering is completed, clean the antenna with solvent and paper towels. Remember, all flux must be removed from the surfaces. At this point you may want to coat the insulating section with a flexible caulking or silicone compound and then wrap the area well with electrical tape to weather-seal the dowel area.

Wiring it

Using a drill press, I used both the 5/64-inch and 3/32-inch drill bits to make the elongated mounting hole in the SO-239 fitting for the hose clamp. I like to use a small drill first and then the 3/32-inch bit, since that almost eliminates the need to file the opening. If you have a small file, you can use it to make a better-looking opening. Solder the length of copper wire to the center terminal of the SO-239. Mount the fitting to the 1/2-inch copper tubing with a stainless steel hose clamp. Attach the SO-239 feedpoint assembly with clamp to the 37.5-inch section of 1/2-inch copper tubing about 2-1/4 inches above the crossbar. Using the other clamp, mount the loose end of the wire to the 12.5-inch section of 1/2-inch copper tubing, also about 2-1/4-inch above the crossbar. After attaching the completed feedpoint, trim off the excess wire from the clamp area.

Tuning it

I clamped the base plate to my stepladder to use as a test stand. Using a support like this will make it easy to adjust the feedpoint for lowest SWR, and provide a handy shelf on which to set your tools, radio, and SWR bridge. First check the SWR at the top, middle and bottom of the band. If you started with the 2-1/4 inch above the crossbar measured at the bottom of the wire, the lowest SWR point should be very close. Move the feedpoint up or down no more than 1/16 of an inch at a time, checking the SWR reading after each adjustment, until you are satisfied.

After tuning the antenna, scratch a mark where each clamp mounts, and then remove the clamps to give the antenna a final cleaning. Remove *all* the flux and skin oils left from handling the copper with bare hands. Polish the complete antenna with a scrubber pad at this time. Reinstall the feedpoint clamps and recheck the SWR.

Spray the entire antenna with clear exterior lacquer, varnish, or sealer to keep it looking new for years. If you want to apply a little silicone sealer to the back of the SO-239 where the wire attaches, do so now.

Notes on it

It can be easier and more fun if you and a friend build your Super J-poles together, maybe even as a club project. Tune the antenna in an open area away from any wires or large solid objects that may give you false SWR readings. The 3/16-inch tubing should be bent into a half circle pattern, with about a 5-inch radius. You will want about 1-3/4 inch of space between the upper and lower halves of the 3/16-inch tubing. The distance of the end of this matching section from the vertical sections of the antenna will affect tuning to a minor degree, but it also helps balance the antenna.

Be sure to use an SWR meter that is accurate at 225 MHz. Most HF SWR bridges are not much good for VHF. Tape your coaxial connection well to seal out the weather, and tape your feedline to your mast; keeping it taped means less stress, and less possibility of future flapping.

Anyone with questions about my antenna designs may write to me direct, sending a #10 SASE. 73

The Difference Is Dedication

Ham radio saves four communities.

Alfred A Mikalow III K7OOZ
55371 McDonald Road
Vernonia OR 97064

The snow had been building up in the mountains. In a week, at the 1200-foot high Vernonia Peak Observatory, 15 inches had fallen. The higher mountains had received two feet or more. Then the rain started. A layer of ice half an inch thick covered the snow. On February 4, 1996, weather patterns changed and the Jet Stream moved from the Arctic to the Tropics. The precipitation changed to warm, heavy rains, and the temperature went up to the mid 60s. The ground had been saturated since before the snowfall; it couldn't handle any more water.

The problem was exacerbated by the clear-cutting of timber in the Coast Range mountains. Without the roots of trees to hold the ground in place, the earth moved. Whole mountainsides collapsed, destroying bridges and roads.

On the 5th and 6th of February, the waters started to rise. By the 7th, most area rivers were well over their banks. *All* the major rivers in the Northwest were overflowing by February 8th. Portland was sandbagging the seawall on the Willamette River. The Columbia River, as well as any other stream in the area, was above flood stage by several feet.

The 1996 flood peaked on February 9th on the Nehalem River in Vernonia, flooding about two thirds of the town. In places the water was as much as 8 feet deep, leaving a layer of mud wherever the waters touched. On February 8th the only local hams still able to operate, Cherie KA7ILQ and Norm KB7CD, put their amateur radio skills to work.

Landslides had taken out the police and fire 911 lines. The roads were washed out or covered by slides. An amateur radio station was set up at the firehouse, and for nearly a week, the hams would be the only means of communication in or out of the area. Over half of the homes in Vernonia had been flooded.

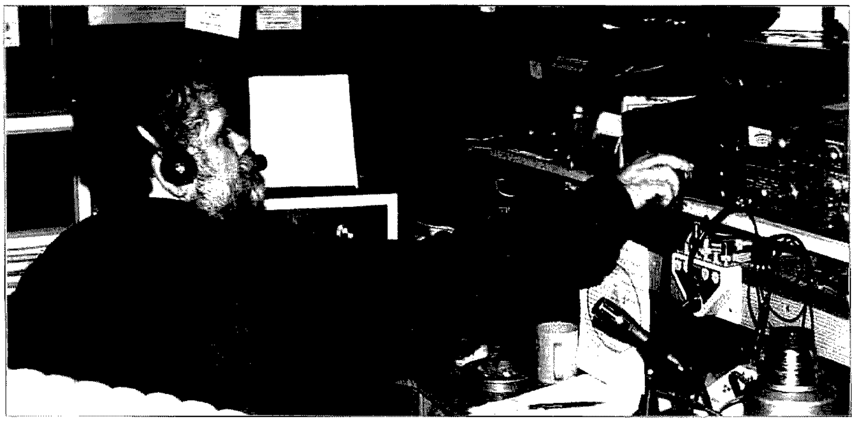

***Photo A.** One hero ham: Bill N7VZF ran the emergency net.*

On the evening of Thursday, February 8th, the Vernonia hams were sending through requests for food and other supplies. The hams who received those requests responded by going to stores in the Beaverton and Portland areas. By Friday, Wes K7WWG and many other hams had not only located the emergency supplies, but were mobilizing the resources to transport them to Vernonia, though the roads into the devastated area were nearly impassable, even for four-wheel-drive vehicles.

By now the Net on the South Saddle Mountain 147.32 MHz repeater in NW Oregon was in full swing. The EOCs for the affected counties were online, as was the Red Cross in Portland. Hams were providing radio links to almost all of the flooded areas in Oregon and Washington.

A call went out to get a helicopter into the Nehalem River valley, to check on flooding there. The call fell on deaf ears, and concerned hams were told by officials that there was no problem. One of the Vernonia hams, Sandy K7OOZ, decided to spearhead a trip out to those areas. Sunday afternoon K7OOZ arrived via logging roads to find that almost all of the homes in Mist had been flooded. Emergency supplies were requested from Vernonia and by that evening six pickup truck loads arrived, at about the same time as the National Guard. Sandy stayed in Mist and the rest of the group went into other communities. Randy

KE7AF set up a ham station in Mist and worked with the National Guard and the Mist fire station. Again, official bulletins declared that there was no problem in Jewell or Birkenfeld. Four days later, it was learned that Jewell had been hit as badly as Mist.

Once again, emergency supplies were gathered and the same basic list the hams had acquired for Vernonia was sent to the school in Jewell. The hams set up a station there as well.On the evening of Tuesday, the 13th, the hams turned the food distribution operation over to the services in place by then. On the following Saturday, a portable Cell Phone transceiver was set up at the Vernonia Peak Observatory to provide communications for the Vernonia area. At 7:00 PM, Sunday, February 18, 1996, the ham network was closed down after eleven days of operation. Out of the eleven days the first four were 24-hour operations.

The devastation caused by the February flooding is hard to imagine, as was the amount of help provided by the hams. Seldom has an amateur operation run as smoothly as this one, thanks to Bill N7VZF who ran the net, and the hams who involved themselves so deeply, often digging into their own pockets to purchase what wasn't donated, and paying for fuel to transport the emergency supplies.

Until Sunday, February 11th, the hams were strictly on their own; there were no other organizations helping with the disaster in this area. At least a hundred hams were involved with supplies and communications; at least a hundred heroes who helped put nearly three thousand lives back together. The list is too lengthy to print here—the honor roll of the hams and other people who helped in the Flood of '96, but they know who they are.

Thank you from the people of Vernonia, Mist, Birkenfeld, and Jewell on a job so well done. The ham radio operators made the difference.

Tape-Wound Antennas

Neat, efficient, and easy to build.

Peter Laakmann WB6IOM
The Highlands
Seattle WA 98177

Using white PVC plumbing components and adhesive copper tape, you can build microwave/UHF helicals or HF/VHF verticals, dipoles and beams; efficient, good-looking antennas that lend themselves to endless fun and experiments.

Simply wind a desired pattern of adhesive copper tape onto the pipe. The tape, designed for direct soldering, can be cut to any width by suppliers from stock "logs" of up to 20 inches, making this a "printed circuit" approach to building antennas. Painting or varnishing the finished design will produce a lightweight, rugged structure, well suited to severe weather. Another option is to Fiberglas™ the finished and tuned assembly.

Because of the skin effect, tape is just as good a conductor as a solid sheet of copper. In practice, tape is a *better* conductor since the surface area can be much greater than wire. Tape is also lightweight and the instant adhesive makes winding with it a pleasure.

Common PVC pipe comes in sizes from 1/2-inch to 4-inch diameters. Sizes between 1-1/2 and 3 inches are ideal for a great variety of HF and UHF projects. You can also wind 13 and 23 cm helixes and straight sections, build capacitive "hats," and do other tricks of antenna construction.

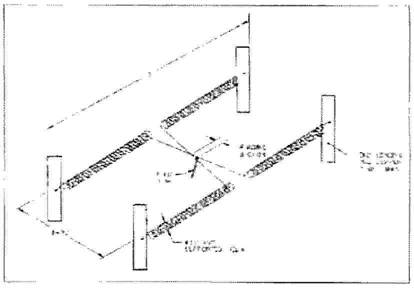

Fig. 1. *Suggested beginning design.*

For UHF applications, the formulas in antenna books for helicals can be followed directly. The PVC makes a convenient support for these circularly polarized broadband antennas. Three-inch PVC tubing in either Schedule 20 or 40 is rigid enough to construct 20 dB gain axial helical antennas for the 23 cm band; a rough rule of thumb is a circumference of one wavelength. Popular antenna books can provide complete details for pitch, match and ground plane dimensions. Performance should be essentially the same as any air-wound helical since the PVC dielectric loss is not likely to be significant.

As HF antennas, the tape-wound structure acts as a uniformly loaded transmission type structure that is electrically shortened relative to a free space dipole. The amount of shortening can be controlled by tape width and pitch. The advantage of the structure, aside from its simplicity, is the low loss or high electrical efficiency. A good starting point for resonance is that the physical length of the unwound tape is about one wavelength for a dipole.

This method of building small, efficient antennas compares favorably with small loop antennas. For a given maximum physical dimension both loops and dipoles have the same maximum possible bandwidth. However, a 10-foot-long dipole is lot less cumbersome than a 10-foot-diameter loop. This means in practice that a loop antenna is built to smaller dimensions and will then require remote tuning. Such remotely tuned tape-wound antennas (TWAs) have much to offer the home builder since everything needed can be found at the local hardware store, and a reasonably sized TWA can have adequate bandwidth without the complexity of remote tuning.

Performance

All small-wavelength antennas suffer conductor loss, but this is where the TWA shines. First, copper conductivity is better than aluminum, the common material used most in small antennas. Second, when compared with a wire-wound helical resonator, the tape width can be made as wide as the center-to-center turn spacing, reducing the resistance even further. The dielectric loss in the PVC is negligible as there is only a small electrical potential between adjacent turns. For these reasons one can expect the tape-wound antenna to have much greater electrical efficiency for a given length. Because of the large copper surface area, these antennas should be able to handle several times the legal

Continued on page 34

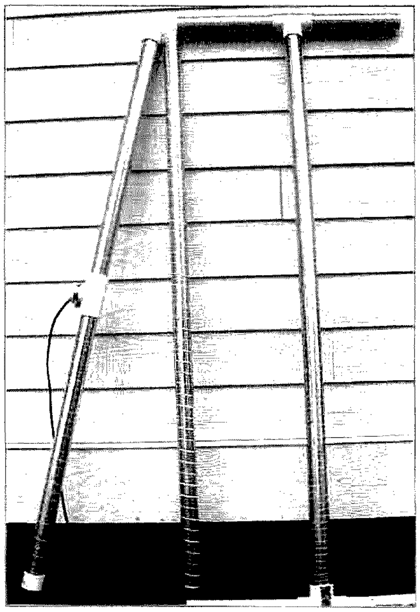

Photo A. *Tape-wound antennas come in many shapes and sizes. Although these are all about the same size, different winding techniques make them resonate at different frequencies.*

NEVER SAY DIE

Continued from page 31

page to help you communicate with the others so you can collectively learn from each other's successes and failures. You'll be way ahead of the other legislators, most of whom haven't any idea of what is going on in the other states.

I'm reserving some covers of *73* for the first few ham state legislators to get elected.

The first step

If you aren't in a position to run for your state legislature, how about getting your ham club members to work on finding a local ham to run? You must have a couple of members who have the time to get this ball rolling. Back them with all of the club members, their families, and as many of their co-workers as possible. With a core of 700,000 (if you bother to get the word out), and at least two more voting family members, plus three friends, we could have one heck of a lot of clout. Let's see, 700,000 divided by 50 states is an average of 12,500 hams per state. If each can generate six votes, that's 75,000 votes per state. And that's a major force.

But it means talking it up at your club meetings, writing articles for your club newsletter, and giving talks. You not only want to talk this up at club meetings, but get around to local business and social clubs. I've been giving talks to New Hampshire (and some Massachusetts) Chambers of Commerce, Rotary, Lions, Kiwanis, and so on. They all need speakers, and your message is exactly what they want to hear. And, being a ham, you're more used to talking than the average person. Hey, at the worst you'll get a lot of free lunches and dinners, plus a bunch of souvenir pens.

The people you'll be talking to are mostly small business owners so they'll be particularly receptive to your message. They know firsthand the results of our lousy educational system and are reminded of it every time they interview potential new employees.

If you're not good at speaking, you will be. All that takes is practice and a good solid knowledge of your subject. I was absolutely awful when I started talking at hamfests. It doesn't take long to get over stage fright. If there's some interest, I'll help with ideas on what to talk about. Or you can go back and swipe stuff from my past editorials. It's all there.

Once in

Step one is to get elected to your state legislature. Then you want to get on the educational committee. Next you want to talk with as many college presidents as you can. I think you'll find them highly cooperative. I know a bunch of college presidents and none have found any problem with my sneaky plan.

The next step is to start talking with local school boards, explaining the need for

Continued on page 35

Tape-Wound Antennas

Continued from page 32

limit in power. The low loss allows you to build efficient short antennas. Simple calculations and tests bear this out:

The radiation resistance for short uniformly loaded monopoles is given by $h^2/312$ for electrical height (h) less than 45 degrees (1/8 wave). The radiation resistance of a dipole is double those values so that the radiation resistance of a short uniformly loaded dipole becomes $H^2/624$ where H is the dipole length in degrees. RF (skin) resistance of the 1.4 mil copper tape can be calculated from formulas or curves supplied in standard reference texts. However, these values are optimistic as they only apply to isolated straight conductors having a diameter much larger than the skin depth. The skin resistance is increased by the proximity effect. For a solenoid type winding using either aluminum or copper, the RF resistance is increased beyond the calculated skin resistance by as much as a factor of two.

I did some measurements of total loss on short sections with a "Q" meter, allowing me to calculate the total effective RF resistance on full-sized TWAs. Short 7- and 10-turn sections wound on 1-1/2 inch PVC tubing were used and measurements were made at 18 MHz. "Q" values of over 700 were obtained. The RF resistance inferred from Q measurements tends to be pessimistic for high values of Q because of losses due to radiation and resistance in other components of the meter circuit. The worst case estimate thus obtained showed RF resistance only about 50% greater than the calculated values that assume isolated straight conductors. These calculations assume current flow on the inside of the coil only. Therefore, calculating skin resistance from standard formulas by using tape width = wire circumference creates worst case errors of a factor of 1.5 (50%).

The radiation resistance of a 10-foot-long 3-inch-diameter helical resonator at 14 MHz calculates as 4.5 ohms. The loss resistance calculated for 1.5-inch-wide tape (56 feet) is 0.5 ohms; it is identical to the skin resistance of a 1/2-inch-diameter copper tube since both have the same surface area. This value must be divided by two because of the current distribution. Antenna efficiency is therefore about 95%. This represents about a 0.25 dB gain reduction over a full-length 33-foot dipole. The difference would be totally undetectable in on-the-air tests. For other shortening ratios, keep in mind that further shortening not only decreases the radiation resistance with the square of the length, but decreases the bandwidth even faster. The fractional bandwidth (without resistive losses) decreases with the third power of length!

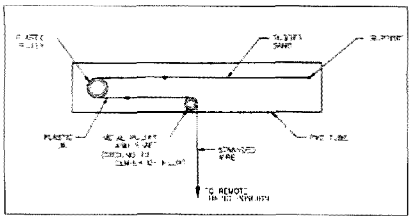

Fig. 2. Construction details.

Construction

Photo A shows a few of the structures tested using 1-1/2-inch pipe (1.9-inch o.d.). Three different tape widths were used to evaluate self-resonant frequencies. All structures are 5 feet long, using tape of 1/2-inch, 3/4-inch, and 1-inch width, closely spaced. The structure using end loading resonates at around 14.3 MHz using 1/2-inch tape. End loading stubs are 1 foot long and carry two strips of tape on opposite sides of the stub. The 3/4-inch tape structure resonates at 29 MHz. The 1-inch tape structure resonates around 45 MHz. 2:1 VSWR bandwidth of the 29 MHz TWA was measured as 250 kHz. A 14 MHz radiator of twice the dimensions would therefore yield a bandwidth of 125 kHz. Note the support tube attachment on the 29 MHz radiator. Using a saw, a "T" fitting is split, placed over the center coax connection, and clamped to the support tube with a hose clamp. The coax can then run down inside the support tube. Use good strain relief on the coax, because the tape is not strong enough to withstand pulling.

Scaling laws apply; doubling all dimensions will cut resonance frequency in half. That means doubling tape width, diameter and length of the PVC tube. Tape thickness does not affect resonance much, so it does not have to be doubled.

Close spacing, edge-to-edge, on the tape reduces ohmic losses. Losses are inversely proportional to tubing diameter for a constant tube length as tape width can be increased. However, when winding UHF helical resonators for use as axial beams, use wider tape spacing as more RF voltage exists between turns. Copper loss is not a problem in that case. I suggest using only 1/2-inch-wide tape for axial radiators.

Feeding and matching cable to HF TWAs is a snap. For a horizontal dipole, connect the coax shield to the center of the antenna (zero voltage point) and move the inner conductor to a point a few turns away until an exact match is found. No balun is required. For the test 29 MHz dipole (5 feet) with 3/4-inch tape the match was found at two turns. For the 14 MHz end-loaded dipole, the match was also found at two turns. If the frequency is off, simply unwind some turns and add a little tape or apply any form of end loading. The tape can be spliced and soldered easily.

For vertical dipoles the same principles can be used if the coax can be brought back at 90 degrees from the center. Monopoles working with a good ground plane are very simple. Just connect the end of the tape to the ground plane and the coax shield, then find the proper turn for the match as above. Make sure the ground plane resistance is less than the radiation resistance as calculated above. A half-wave monopole has a radiation resistance of only about 3 ohms! Of course, you can use two or three TWAs rather than full-length 1/4-

Continued on page 46

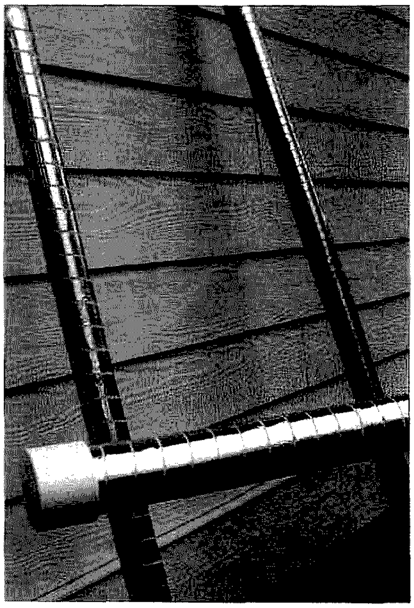

Photo B. Here's how to wind the tape onto the mast: close, but not touching.

Continued from page 33

change, and the low costs to their dictricts.

It's even possible to set up electronics labs for schools for next to nothing. Here in New Hampshire a friend of mine has been collecting no longer needed test equipment from electronics firms, refurbishing it, and giving it to local schools. He's found good school homes for hundreds of oscilloscopes and so forth. It's a nice nonprofit business that allows the donating companies to get a tax credit for their donations. Everybody wins.

I've got a lot more ideas along this line, but you don't need them now.

Who better to push for high-tech education than someone with electronics smarts like you?

Now, look around you. This is something that really needs to be done. If you don't do it, who will? It comes down to *you*.

Money

During the interview on the Art Bell W6OBB radio talk show I mentioned that if you're a ham you really should live on a 200-acre farm so you'll have plenty of room for antennas and no neighbors to bother. Well, obviously that takes money, Art pointed out. To which I replied that making money is easy, once you know the secret. Then we got off on another subject.

This resulted in several hundred people writing to ask about the secret to making money. So I sat down and wrote an instruction book, explaining the secret, and I put a $5 price tag on it. People might pay more attention if I charged $5,000, which it's well worth.

Several *73* readers have written recently asking about how to make money, so I suppose I should write about that now and then. I need an index to my editorials because I know I've written about this before. Probably many times.

Yes, it's possible to start from scratch and become a millionaire within seven years. Heck, it shouldn't take more than five years, if you're really serious about it. But that means throwing out almost everything you've been taught. Judging from the trouble I've had getting readers to change their diets so they won't be fat and sick, getting you to change your loser's approach to making money may be an even greater challenge.

The chances are that you haven't put any more thought into your future than I did when I was young. I took what came along. Everyone had to go to college to be successful, so I went to college. A war came along, so I went to war. After the war, like most everyone else, I went back to college. When I got out I started, for the first time, to think for myself. Instead of jumping into a big corporation like 99% of my school buddies, I said to hell with that and got a job as a chief engineer-announcer in a small North Carolina radio station. Small business. I handled the engineering, wrote and sold advertising, wrote programs, and had a great time announcing and doing DJ shows. I learned a lot and got very good at what I was doing.

But you're not interested in another Wayne Green bio. You are probably much more interested in how to make money. How to make a lot of money.

The basics

For starters, if you want to make money, doesn't it make sense to at least head your career in that direction? Or a second career, if you've screwed up the first.?And that means avoiding career choices which are never going to make much money. Like working for a large corporation, for instance. Another bummer is working for the government. A third route to nowhere is teaching. And what do our colleges aim you toward? Big business and teaching. Sucker.

They really love it when I lecture at universities on how to be successful. Well, actually, they don't invite me back as often as you might think because my message is that college is a total waste of time for anyone who wants to make money or accomplish anything significant. Even the professors get all upset when I discuss this because they realize for the first how badly they've been had by the system.

Remember John Taylor Gatto, the New York State Teacher of the Year, who pointed out that it only takes about 100 hours to teach a kid to read and write? Yet we have kids who manage to go through K-12 and four years or more of college without ever learning to read, much less write. If you think college grads can write you should read some of the mail and even articles I get. Pathetic!

My four years of college were pretty much a total waste for me, except as a bad example.

Yes, believe me (if you can), I know all of the arguments you're going to bring up. Sure, on the average college grads make more money than high school grads. But when you start looking into successful entrepreneurs, you're going to find the statistics show that few ever graduated from college. Many tried college and got fed up, thus putting them a few years ahead of the kids that hung in there for their diplomas.

There are very few jobs out there requiring a college diploma that are going to be very helpful to you in a career aimed at making money. Like just about none. So, if you are interested, no matter how old you are, in making money (isn't it about time?), you're not going to go back to college and piddle away another year or two. Or four.

Let's say you are in your 50s and could be downsized out of a job at any time. What then? Stacks of resumés? A few job interviews, followed by excuses. However, instead you can start from scratch and make it big time in five to seven years, depending on your dedication to success. If you're going to spend a lot of your time watching ball games and eating potato chips, you aren't serious. That's the route to oblivion, probably via a

Transmitter Hunting Equipment: A Club Project

Stimulate and strengthen your club membership.

Sam Guccione K3BY
110 Chalet Ct.
Camden DE 19934

Over the last several years a few members of the Kent County Amateur Radio Club (KCARC) in Dover, Delaware, have been active in T-Hunting. T-Hunting or transmitter hunting (also called fox hunting) is an amateur radio sport in which a transmitter, usually on 2 meters, is hidden, and hand-held radios with special electronic devices and directional antennas are typically used to find it. Joe Moell and Thomas Curlee have written an excellent book on this subject *(See "Sources" at the end of this article).*

Breck Smith K4CHE got me interested in T-hunts. The T-hunt bug bit so hard that I started harassing other club members to get involved. This reached such a level of intensity that I decided the only way to get enough hunters was to help people acquire or build the necessary equipment.

I started by using a simple device called an active attenuator. I constructed and used one described by PAØZR *(Sources)*. The design is very simple and a PC board is available from FAR Circuits. I was so pleased with it that I immediately built more. I gave away two and some parts for a third to encourage T-hunting. Well, this escalated into several club members' requesting lists of parts and where to get them, and from there it became a club project. Along with the active attenuator, some type of directional antenna is needed, plus a hand-held radio.

I designed a simple three-element beam to be used with the active attenuator, which several hunters have already copied. Let's build one!

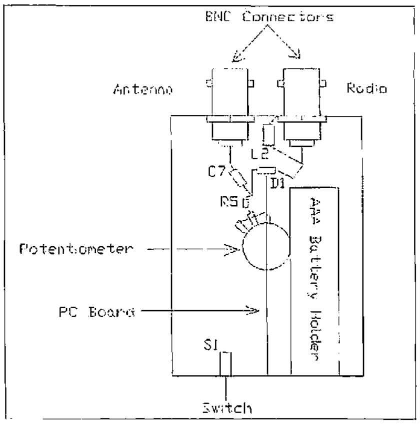

Fig. 1 Attenuator parts layout of inside of box. The PC Board is shown in a vertical position.

Constructing the active attenuator

Dave Holt N3RAE and I compiled the parts list shown for the PAØZR unit. If your club's members have well-stocked junk boxes, you may not need to order all of the parts on the list. Our club members paid half the cost of the kits and the club paid the other half. We built 27 attenuators, assembling eight of them in a couple hours during a regular club meeting. **Photo A** shows the top view of a completed attenuator. We used a regular potentiometer instead of the slide pot of the PAØZR article—it was a lot easier to drill a pot hole than to try to cut a slit for a slide pot. The switch on top marked "–25 dB" is a passive attenuator (described below).

Fig. 1 shows the inside parts layout, with the PC board vertical, supported at two points to simplify construction. Bend one of the potentiometer solder tabs vertical, and solder between the outside ground trace of the PC board and this solder tab. This provides one support point. Apply a dollop of hot glue between the PC board and the end of the potentiometer to form the second support.

"A bite from the T-hunt bug can start an epidemic of fun for your club, too!"

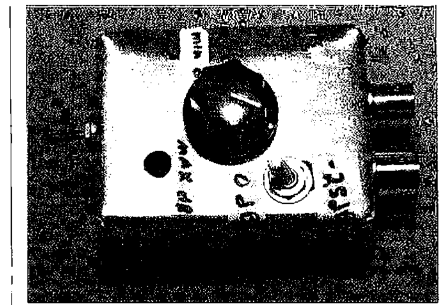

***Photo A**. Top view of a completed attenuator. (Disregard the hole below the words "MAX dB"...nobody's perfect.)*

Since an AAA battery was used instead of the hearing aid battery used by PAØZR, a small change in the connection to the PC board is required. Wire the red (positive) wire of the battery holder to the on/off switch. Connect a wire from the on/off switch (S1) to the hole just to the right of the silkscreened area on the PC board. Then solder the black (negative) wire anywhere convenient on the ground trace, which encircles the outside edge of the board.

Hot glue the battery holder to the box. The other parts shown in **Fig. 1** are self supporting after they're soldered in place. One ground lug was used under the ANTENNA BNC connector (J1) for the ground connection of L1 and to provide a chassis ground for the PC board. Be sure you connect the PC board ground trace to the metal box, or the attenuator will not work.

The circuitry is not critical and relatively long wires may be used instead of the compact construction shown. (See **Photo B** for the construction technique used by one club member in his attenuator.)

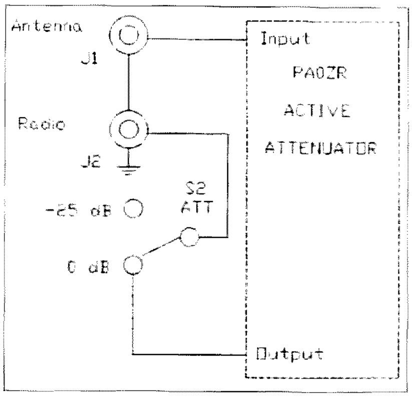

Fig. 2 Wiring diagram of attenuator with passive attenuator included. The passive attenuator is an SPDT switch.

Jerry Palmer N3KRX provided the idea to add a passive attenuator to be used in series with the active attenuator—it's just a SPDT switch wired as shown in **Fig. 2**. It provides 20 to 25 dB of additional loss, which (added to the active attenuator loss) gives 100 to 120 dB of attenuation for getting close to those high power hidden transmitters. If you feel that the passive attenuator will complicate your project, leave it out. Remember to wire the connector J2 directly to the active attenuator in this case.

Active attenuator operation and adjustment

The active attenuator works by mixing an incoming signal with a frequency generated by an oscillator inside the attenuator, to produce an output signal at another frequency. The oscillator frequency of this attenuator is 0.5 MHz. So if a 146.5 MHz signal is incoming, a signal of 147 MHz (146.5 + 0.5) is produced at the output of the attenuator. Since the attenuator is connected to your hand-held radio, this is the frequency that your radio should be set to. The potentiometer controls the signal level that goes to your hand-held. About 80 to 100 dB of attenuation is provided by this simple circuit. By the way, a frequency of 146 (146.5 - 0.5) could also be used since the active attenuator produces both sum and difference frequencies.

Adjusting the attenuator is simple: using the following procedure. Connect your HT, which should be set to 147 MHz, to the attenuator; put the HT rubber duckie on the attenuator input. Have a friend stand 30 to 60 feet away and transmit with his hand-held set as low as possible on 146.5 MHz. Adjust trimmer capacitor C1 for a maximum S-meter reading on your hand-held. (You may need to adjust the attenuator control R6 to keep the S-meter from pegging out.)

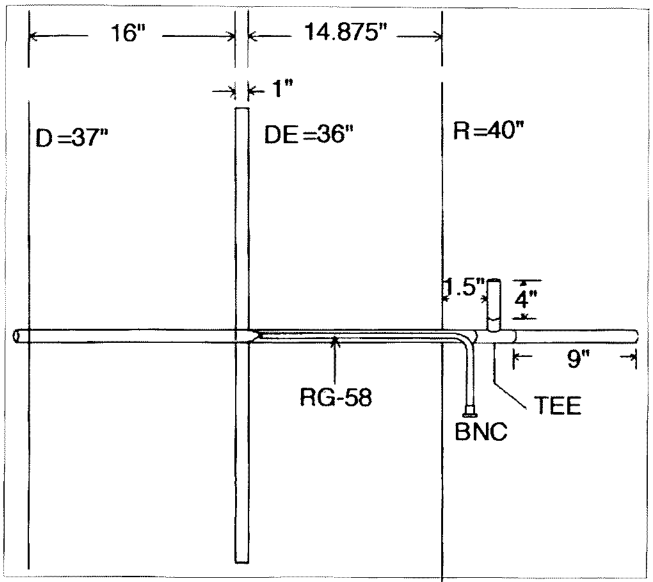

Fig. 3 Dimensions and construction of the 2 meter T-hunt beam. The driven element dimension of 36" is correct. The length was adjusted to achieve a low SWR.

Transmitting test

Although PAØZR didn't mention transmitting into the attenuator, I was curious. I tested mine with up to 5 watts for periods up to 3 minutes, without apparent damage. I would not recommend transmitting through the attenuator, but it is nice to know that if you accidentally key your hand-held with the attenuator attached, you won't burn it out.

Constructing the beam antenna

Many hunters have found that a yagi beam works best in most hunting situations. It is small, lightweight, easy to use in heavy brush, and simple to construct. I used the ELNEC program to design this beam. **Fig. 3** shows the dimensions and construction of the beam.

Brass brazing rods used for construction in this project were 36 inches long. Standard brazing rods are available in diameters of 1/16 inch, 3/32 inch and 1/8 inch. Be sure to use plain brass brazing rods and not the special coated ones or the center core kind.

As shown in **Fig. 3**, the boom is made from inexpensive, easy to use PVC pipe. The pipe tee forms a handle that uses your arm as a support for holding the antenna away from your body.

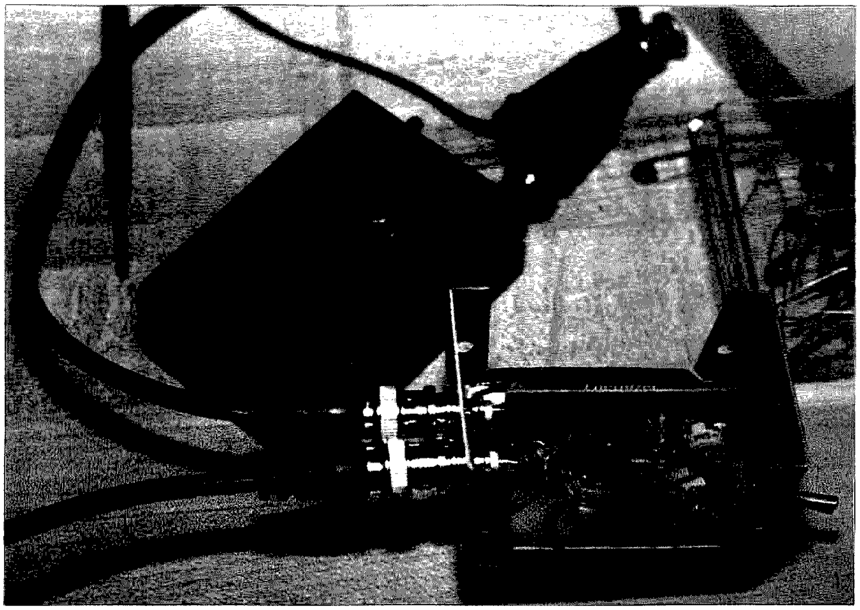

Photo B. *Attenuator construction technique used by one club member, showing long connecting wires.*

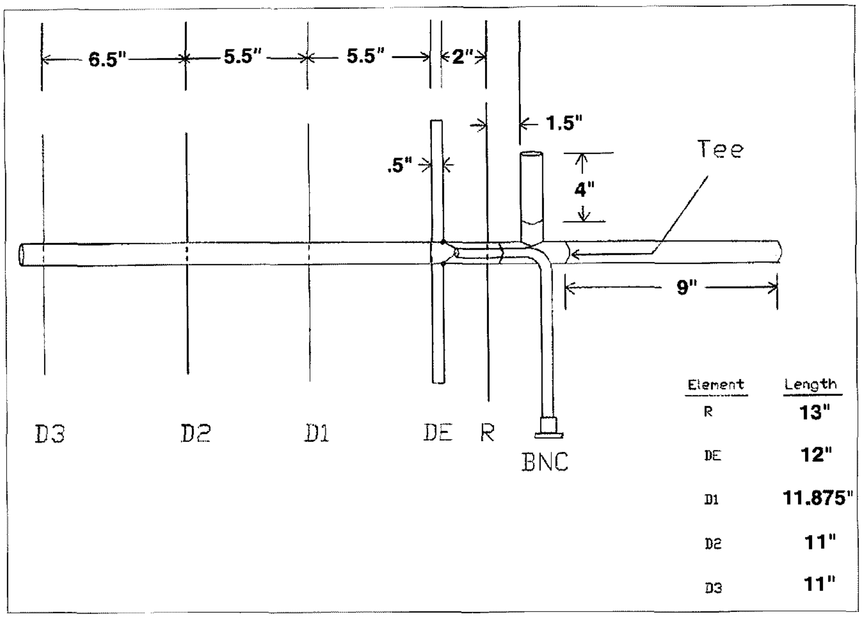

Fig. 4 Dimensions and construction of the 70 centimeter T-hunt beam.

The elements consist of the 36-inch brass rods with pieces of 3/32-inch (inside diameter) brass tubing used to extend the rod to the necessary length. You can probably find brass or copper tubing at your local hardware store or hobby shop.

Drilling the holes in the boom is a crucial step. I used a punch to mark the place in the PVC before drilling the 3/32-inch diameter hole for the elements. To maintain alignment of the holes during drilling, begin by drilling the hole for the director D at the distance shown in **Fig. 3**. Put a brass rod in this hole. Position the PVC so that the drill bit is over the next hole mark. Rotate the pipe until the brass rod is exactly vertical, and you can be assured that this hole will be vertical and in line with the first hole. You will probably want to clamp the PVC pipe. A drill press makes it easy to drill 40 or 50 holes if you are going to construct a large number of antennas, but we also constructed a few of the antennas with a hand drill. It took two of us to keep the drill straight so that the holes were aligned, using the brass rod for an alignment device as described above.

I made the director D by cutting two 2-inch pieces of the brass tubing. I slipped the pieces over each end of the rod, slid them so that the overall length was 37 inches with 18.5 inches on each side of center, and soldered the tubing in place. Be sure to mount the rods through the boom before soldering the tubing pieces.

To finish, you can put pipe caps over the three open ends of the PVC pipe, or not, as you prefer. They do not affect the electrical performance of the antenna.

I used a folded driven element (DE) in this design to raise the impedance, which should lower the SWR. The final SWR of my beam as measured with an MFJ-259 SWR meter was 1.1 to 1. Other antennas constructed by club members had SWRs of 1.1 to 1 up to 1.5 to 1.

The feedline is connected directly to the folded element. Antenna purists may object, citing lack of balance. However, I have built quite a few of these antennas and have not experienced significant pattern distortions; variations are not noticeable when using the antenna for T-hunting.

Hunting in the 70 cm band is catching on in various parts of the country, including Delaware. Since the active attenuator works well in this band, I have included the design and construction details of a 5 element 70 cm beam (**Fig. 4**).

If you purchase the materials for this beam at the same time you purchase materials for your 2 meter beam, you can reduce the cost of the 70 cm beam substantially.

The same construction techniques used in the 2 meter beam are used in this design. The SWR of my 70 cm beam was 1.8 to 1 as measured using an MFJ-219 UHF SWR analyzer. I have used this beam during a few 70 cm hunts held here in Delaware and found it to have a very sharp pattern.

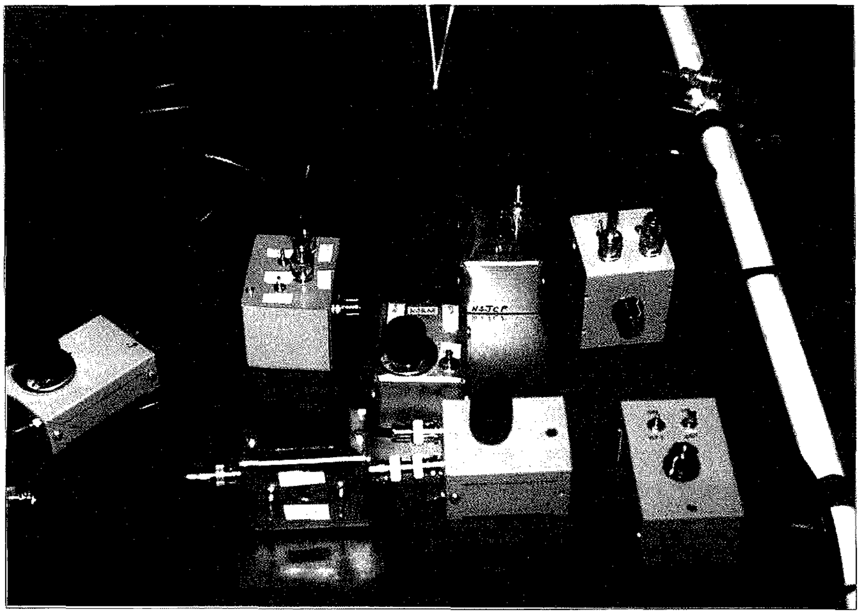

***Photo C.** Some of the newly constructed attenuators at end of the club meeting night.*

Testing the beam antenna

Connect your active attenuator to your hand-held, and the beam to the attenuator. Note that the coax jumper cable connects from the attenuator output to your hand-held antenna jack. Hold your beam with the elements vertical, as it would be used in most T-hunts. Make sure your hand-held is set to a frequency of 147 MHz.

Have a friend standing 30 to 60 feet away transmit with low power on a simplex frequency of 146.5 MHz. Point your beam at your friend and adjust your attenuator to produce a one-half to three-quarter scale reading on your S meter.

Swing your beam slowly to the left, then to the right. You should see your S-meter fall off on either side as you point away from your friend. Rotate your beam completely around in a circle. You should see your S-meter reach a peak value when the beam is pointed at your friend. You will also get an S-meter reading when you point your beam directly away from your friend, but this reading will be much lower than when the beam is pointed at him.

Change the antenna to the horizontal orientation and repeat the above tests. You should find the maximum S-meter reading occurring in the same direction as your friend's transmission. If neither of these tests works as described, have your club's technical expert check your antenna.

After our club members completed their attenuators and antennas, practice hunts were held, starting with a walking hunt. A small T-hunt transmitter was placed about a half mile from the hunters. I have written out the procedure we used and have included it below.

To the field!

First set the attenuator for minimum attenuation (maximum signal reception). Rotate the beam quickly around in a circle to get a rough direction, then fine-tune by moving your antenna in smaller arcs to find the maximum signal. Taking a bearing with a pocket compass can help at this point.

Begin walking in the direction of the bearing. Be ready to take a new bearing any time the hidden transmitter identifies. As you get closer to the hidden transmitter, you will need to increase attenuation by turning the knob. You can get a "feel" for how close you are to the transmitter by noting how much attenuation you have at each reading you take.

Well that's it. We ended up constructing a total of 27 attenuators and 15 beams as a part of our club project. Participation in local fox hunts has boosted our enthusiasm and our membership—we picked up a number of new members.

I wish to thank the members of the Kent County Amateur Radio Club (KCARC) in Dover, Delaware for their support in making this project a success. Special thanks go to Breck Smith K4CHE, my sounding board and technical advisor, and to the KCARC club president, Richard Lomax N3JCP, for taking the photos.

***Photo D**. Breck Smith K4CHE aligning an attenuator using his spectrum analyzer (on the left).*

I would be happy to answer questions or provide details not described to anyone deciding to take this project on. I may be reached by E-mail at sguccion@outland.dtcc.edu or by regular mail at 110 Chalet Court, Camden DE 19934.

Simple Multi-use Amplified Speaker

J. Frank Brumbaugh KB4ZGC
P. O. Box 30 - c/o Defendini
Salinas PR 00751-0030

So you've built that nice kit transceiver, and you want to use it in your shack. You've got two problems right away. First, it was probably designed to run off batteries, and second, it probably doesn't have enough audio power to drive a speaker.

Many kits are designed that way to save money and to make them portable. The power supply and audio amplified circuits add weight, raise costs and create current drain that makes the units difficult to use in the field.

For everyday use, many hams add a regulated power supply and use their field units at home. The power supply doesn't solve the audio problem, however. If an audio amplifier and speaker is added to an existing receiver or transceiver it is not available for any other use. It cannot also be used on a different receiver, nor as a test speaker when checking designs of audio circuitry.

What is needed is a compact, lightweight, self-contained amplifier and speaker with volume control, and a headphone jack that can mute the speaker. It should be capable of producing normal room volume while requiring minimum current with no or minimal distortion. It should be capable of being powered by either an internal 9-Volt battery or an external 12-Volt battery or 13.8-Volt power supply. It should use few and inexpensive parts, and be easily constructed and used by any ham. The unit described here meets all these requirements.

"Self-contained, lightweight—it uses almost no power, yet you get wonderful sound! At home or in the field, you'll be proud of this project."

The Circuit

Fig. 1 is the schematic diagram of this amplified speaker. S1 is a SPDT toggle switch with a center-off position (on-none-on). In one position it connects the internal 9-Volt battery to power the amplifier. In the opposite position it connects the amplifier to J3, to which is connected an external storage battery or regulated power supply. When the unit is not in use, the switch is centered.

U1 is an LM386 audio amplifier chip in an 8-pin DIP package, wired to produce maximum gain at minimum current. In operation, low level audio is fed through J1 (audio in) through isolation capacitor C1 to the top of the volume control R1, a 10k audio-taper potentiometer. Audio taken from the wiper of R1 passes through isolation capacitor C2 and is applied to one input of amplifier U1. This input is lightly bypassed by C3 to prevent U1 from picking up stray RF, including that from any local AM broadcast station, and serves to stabilize the amplifier. Amplified audio is taken from pin 5 of U1 through coupling capacitor C7 to closed circuit jack J2 (PHONES) and then to the speaker, LS1. Mute the speaker by plugging headphones into J2.

Construction

U1 and associated components should be mounted on a small piece of perf board or one of the general purpose printed circuit boards available at Radio Shack™. C3 should be mounted with short leads between pins 2 and 3 of U1. Mount C4 at the end of U1, where pins 1 and 8 are located. Mount C6 with the shortest lead possible to pin 6 of U1. You may wish to use an 8-pin DIP socket for U1, but it is not necessary.

This unit should be constructed in the smallest case that will hold your components. The speaker should be small, yet have a large magnet and be rated for 1/2 watt or more. Recommended is a 1-Watt, 8-Ohm speaker intended for cellular phone use. It is 1.8 inches in diameter. Magnet diameter is 1.35 inches. It is available from All Electronics, P. O. Box 567, Van Nuys CA 91408-0567. The catalog number is SK-175. However, you can use any 4 or 8-Ohm speaker you have in the junk box.

A small aluminum box will make the best enclosure, but you can use a plastic box, or make one from pieces of printed circuit board material. You can drill a series of small holes in the circular area of the panel behind which the speaker will be mounted. You could also cut a circular hole for the speaker and use a piece of screen wire or perforated aluminum as a grille over the hole to protect the speaker cone.

Mount LS1, J1, J2, S1 and R1 on the panel. Mount J3 on the rear of the enclosure. Put rubber feet on the bottom to prevent scratches.

Battery BT1 can be mounted internally in a clip, or you can use self-adhesive strips of hook-and-loop.

Operation

Connect a source of audio, such as the output from the headphone jack of your receiver, to J1. Switch S1 to INT

to use the internal 9-Volt battery, or to EXT, if an external power source is connected to J3. Adjust R1 for a comfortable volume level from LS1. If there is too high a level of audio at J1, it should be reduced at its source. If you plug headphones into J2 the speaker LS1 will be muted, and you will have to reduce the volume level with R1 for a comfortable listening level. Because this unit is essentially noise-free, any noise you hear will be coming from the source plugged into J1, and will be amplified along with the desired audio.

When this unit is working, the LED D1 will be lit. When it's not being used, place S1 in the center (OFF) position; the LED will go out.

Using the internal battery, or with an external 9-Volts applied to J3, and no audio input, the amplifier draws 8 mA. With R1 fully clockwise (maximum gain) you will hear no, or almost no, white noise from the speaker or in the headphones using the internal battery for power. Any noise heard with an external power supply will originate in the power supply itself under these conditions.

With the audio level set at comfortable listening level, current drawn on CW or voice peaks can reach 50-75 mA. However, since this occurs only on peaks, the average current drain will be between one-third and one-half the peak current drawn on peaks while a signal is present.

Parts List

BT1	9-Volt Alkaline Battery
C1, C2	1 µF 16 V electrolytic
C3	470 pF ceramic disc
C4	10 µF 16 V electrolytic
C5	0.01 µF ceramic disc

How to Make an Old HW-8 Come Alive

New life for a vintage rig

Gerald F. Gronson K8MKB
3529 Belinda Dr.
Sterling Heights MI 48310

The next time you see an old Heathkit HW-8 at a flea market, grab it. With maybe an hour's work you can put some pep into this old "hot-water" baby and have fun. Here's how I substantially improved one.

In looking at the schematic, I could see that the receiver section was pretty good, but that the resistor and capacitor values were not the best choices. I could squeeze better performance out of this puppy.

Since the audio board (**Fig. 1**) was the easiest to get at, I started there. The output transistor was only loafing, so I changed C201, C204, R202, and R205 as per the parts change list to pep it up.

Having experimented with op-amp active filters, I thought the capacitor and resistor values of the stages built around IC2A and IC2B could be improved. Using a 750 Hz center frequency, the new R and C values brought the narrow filter section into alignment. The audio and RF gain controls now had to be turned down on loud stations.

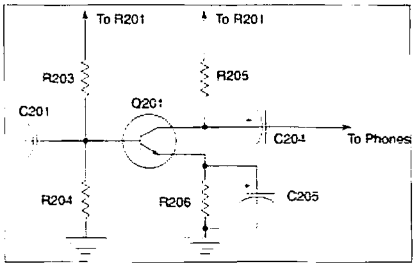

Fig 1. Audio board.

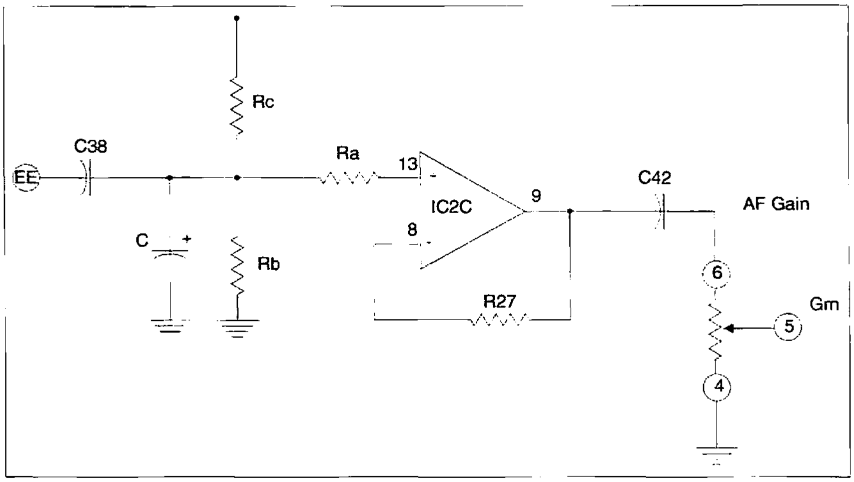

Fig. 2. Ra and Rb form a bias network for IC2C.

Hmm, let's see, what else could I change? IC2C looked like a good stage to fiddle with. What about C38 and C42? Yep, changing them helped a lot.

Next came the IC1 stage. I tried several values for R14, which had been 100 ohms, settling for 180 ohms. Increasing R14 much beyond 220 ohms causes oscillations.

One more stage to go. The RF amplifier was the kicker. Q1, #417-169, is an MPF105 — the worst possible choice they could have made for the RF amplifier. I replaced it with an MPF102, which is not the best possible FET to use. There are better transistors; however, the MPF102 *is* an RF type transistor and is a *much* better choice for Q1 than an MPF105. A coupling capacitor would be better than MPF105. For a good choice of transistors, see *The HW-8 Handbook*, by Mike Bryce WB8VGE. Mr. Bryce has a number of suggestions for making what amounts to a vast improvement in the Heath HW-8.

I suggest you change only two or three parts at a time, then put the rig back together enough so that you can turn it on and check its operation. Then proceed with the next three parts. This will ensure that if you make a mistake it will be easier to correct. Use a low-wattage soldering pencil and some Solder Wick to desolder the old components. A Radio Shack™ desoldering iron works just fine.

To reduce the internal circuit noise remove the 2.2 meg R26 and drill a little hole in the circuit board with an

X-acto knife where R26 was. Replace R26 with a tripod-like group of Ra-Rb-Rc (see **Fig. 2**). Ra should be the same value as R27. Replace R5 (**Fig. 3**) with R26.

The only other thing is to use a trimmer pot in place of R14 — a 1000 ohm value would do it. There is enough room for one and it makes it easier to adjust for optimum value.

I think you'll be happy with the receiver improvement and be able to have a lot of fun with this old rig. 73

Parts Change List

Part #	From	To

Mikes and Match

Can an ICOM mike talk to a Kenwood radio?

Max Holland W4MEA
7333 Valley Lane
Hixson TN 37343

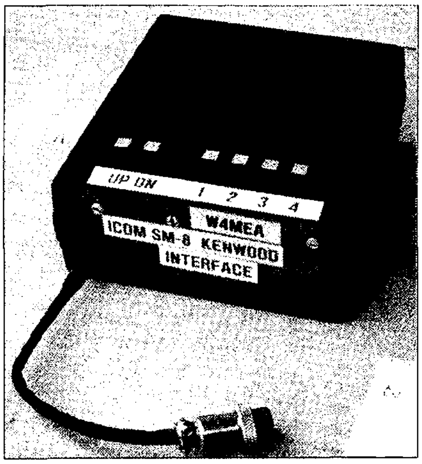
Pull up a seat and I'll explain how you, too, can interface just about any microphone to any rig. All it takes is the brass to outwit the manufacturers. For instance, let me show you how I got an ICOM SM-8 microphone to work comfortably with a Kenwood TS-50-S transceiver. This method can be used for interfacing just about any combination of microphone and radio.

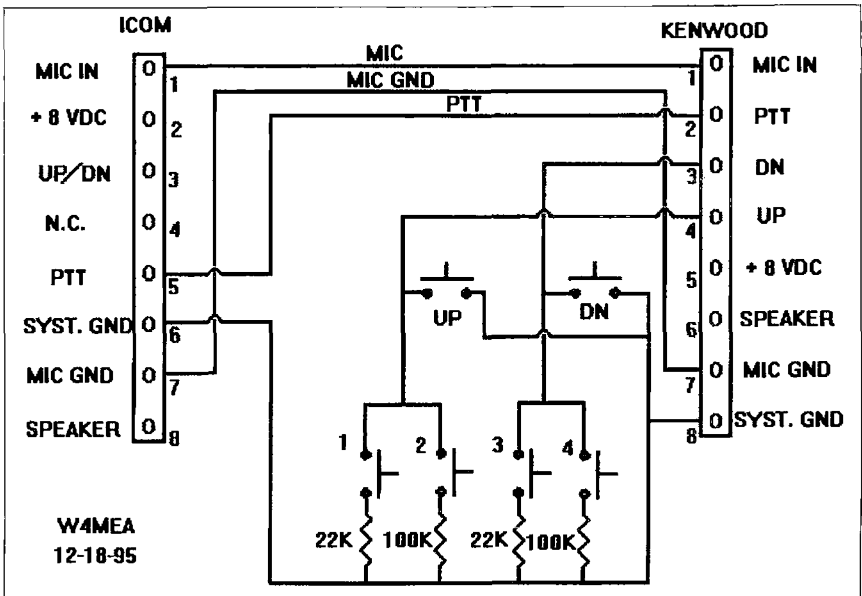
Microphones for Kenwood equipment, naturally, do not match the pin numbers of the ICOM equipment. You expected standardization? However, the voltages and operating characteristics are similar. The ICOM has two buttons on the base of the SM-8, but they do not match the UP/DOWN buttons on the Kenwood, so they are not used. The TS-50-S has an UP and DOWN button on the mike for changing frequency and four buttons for special features. So I built a simple interface box to take the place of the mike buttons and wired them so they'd be usable by the Kenwood.

This is an easy one-evening project that will cost maybe $10. Use some good quality push-button switches. The box can be plastic or metal; however, you want to keep the leads short, since the RF and AF will be close together. 73

Parts List

- 2 22k 1/2 watt resistors
- 2 100k 1/2 watt resistors
- 6 SPST Normally Open (N.O.) push-button switches
- 1 8-pin mike plug (to the Kenwood radio)
- 1 8-pin panel jack (from ICOM microphone)
- 1 Plastic or metal box





ICOM TO KENWOOD MICROPHONE INTERFACE

Build the Neat 2m Amplifier Kit

A great pair of shoes for your HT or data radio.

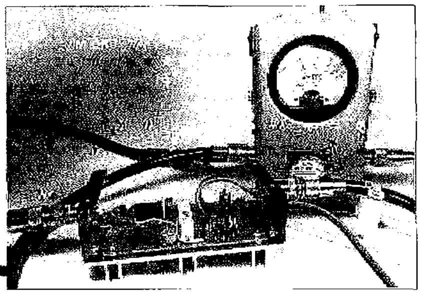

***Photo A.** Tuning it up to 35 watts, just like the specs promised!*

Bill Richarz WA4VAF
10035 Little Creek Road
Charlotte NC 28227

If you are using an HT or other low power radio for packet, you may want to try your hand at building this Ten-Tec 2-Meter Amplifier Kit. Even if you're not using your HT for packet, you can take the "scratch" out of your Handi-Scratchy so everyone will hear you full quieting, and love you for it.

Recently I acquired one of those low power data radios from MFJ. It did a fine job of receiving packet, but with only 5 watts out, there were too many Retrys. There were some stations I could copy well, but they were not hearing me. I needed a boost in power to eliminate the Retrys. Enter the Ten-Tec Kit. Ten-Tec, a well-known HF manufacturer, has a line of small kits in their new T-KIT Catalog. With an RF sensing TR switch and 20 to 35 watts RF output, I decided this little baby would fill the need *and* stay within the budget. Most of the 2 meter amplifiers out there are expensive and usually include a receiver pre-amp, which of course adds to that cost. Ten-Tec holds the price of this kit down by eliminating the pre-amp. Since most of today's 2-meter transceivers are quite sensitive, and the pre-amps sometimes only enhance any intermod, I decided to do without a pre-amp and save the money. The kit costs $74 and also comes assembled (for the lazy) for around $120. Here's where you can save some bucks, and have all the fun of assembling it yourself.

I feel many hams who were not around during the Heathkit era really missed out on the fun of kit building. To take a pile of parts, solder them on a PC board or chassis, and have the whole thing come to life...well, you can't imagine the feeling until you try it for yourself. After all, experimenting and building are an important part of ham radio.

Introduction

The T-KIT No. 1200 offers you the opportunity to construct, understand, and use an RF Power Amplifier for the 2-meter. The amplifier is designed for mobile, portable, and base station operation, providing over 30 watts of RF output, operating from 12-15 Volts DC. It comes with a detailed construction manual and all parts, including enclosure and hardware. Nothing extra to buy — well, almost nothing; they do *not* include those little rolls of solder that Heathkit builders had come to expect. So if you decide to build this kit, go out and buy a roll of 60/40 resin core solder, small diameter. Also, let me say here Ten-Tec does not project this Kit as "Super-Easy." This is a VHF construction project and attention is required in soldering technique and parts placement. Don't be intimidated, though. This can be your first kit, with the help of an Elmer with some experience. You should be able to complete this kit in a single evening. Before you get started, I would suggest reading the complete manual to familiarize yourself with all the parts and terminology used in construction of this kit. Also, you will need a few tools such as a 25-watt soldering iron, diagonal cutters, needlenose pliers, and a Phillips screwdriver.

"You can take the 'scratch' out of your Handi-Scratchy."

Circuit description

Q1 is a VHF RF power transistor operating in Class AB (See **Fig 1**). Bias is controlled by Q2, adjustable by 100-ohm trimmer R2. Q3 and its related components form an RF-sensing circuit which energizes the T-R relay during transmit only. When the relay is not energized, the input is shunted to the output, bypassing the amplifier circuit. This arrangement not only makes the needed antenna connection for receiving, but also permits normal use of the transceiver when the amplifier is turned off.

C5 is adjusted to peak the input circuit at the base of Q1, and C6 peaks the output at Q1's collector. L4 through L8 on the schematic diagram are striplines designed into the circuit board itself. The amplifier may easily be modified for Class C operation, if desired.

Getting started

While the manual provides step-by-step instructions, there are no illustrations other than the circuit board layout and an exploded view of the final assembly (**Fig. 2**). You should check off each step as it is completed in the boxes provided in the manual. Also pay close attention to the orientation of the banded cathode ends on the diodes as they are installed. The PC board is silk-screened with the

component outlines, making it easy to position them correctly. All parts are mounted on the top side of the PC board and soldered to the bottom, except for one transistor which is mounted on the bottom, so there is little chance for error. The one problem you might encounter is the winding of an RF coil. It consists of 12 turns of the supplied #16 enameled wire, close-wound on a standard 1/4-inch drill bit.

The kit may be built for class AB or class C operation, making it suitable for FM, AFSK, AM, SSB, or CW operation. I would suggest building it for class AB, then modifying it for class C, which is what I did. I later cut the two jumpers, making it a class C amplifier for use with my 2-meter FM packet station.

I had no problems mounting and soldering the components to the small board. On completion, it is a good idea to inspect the PC board for bridged solder joints, correct orientation of diodes and transistors, and correct selection of resistors and capacitors. Although satisfied that all parts were assembled correctly, I was a little hesitant in applying power for the first time. Ten-Tec gives no resistance measurements to check before the initial smoke test. I measured the resistance between ground and +DC connection and found it to be about 8 ohms. At least it wasn't a dead short. I hope they will add some resistance checks in later printings of their manual, to give the kit builder a bit more confidence before applying the voltage.

Final assembly and connection

The fully assembled PC board is mounted on the heatsink. End panels with the input and output connectors are also mounted to each end of the heatsink. Soldering the input and output capacitors C7 and C8 to the BNC and SO-239 connectors complete the electrical connections. The power cable is run through a strain relief grommet, then locked into place.

Adjustments

If you build the amp for class AB operation you must make an initial bias adjustment using your VOM. This is clearly explained in the manual. If

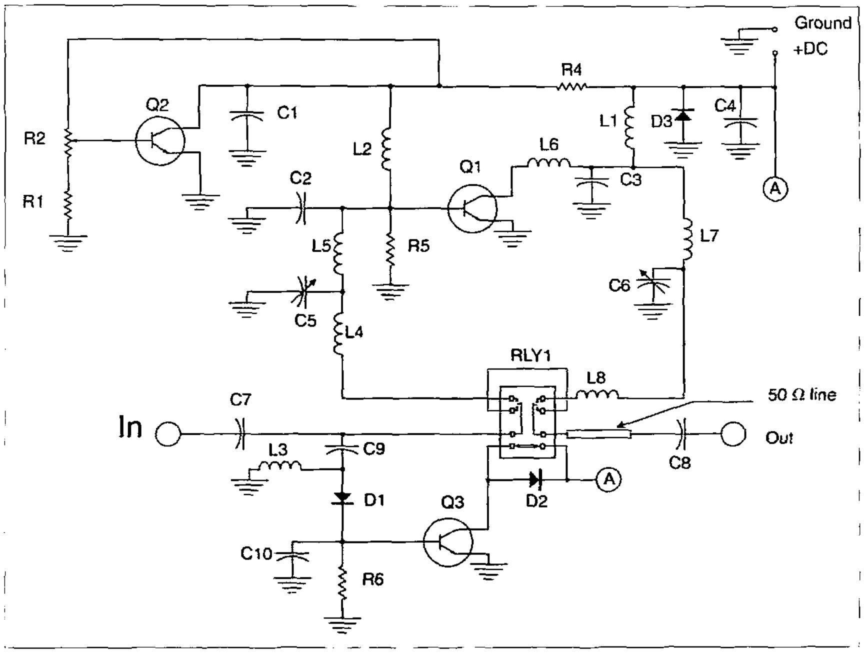

Fig. 1. Schematic diagram.

you built it for Class C only, then you may forget this adjustment. Connect a 50-ohm dummy load or 2-meter antenna to the SO-239 output connector through an RF wattmeter or SWR/wattmeter. Connect your low-power HT or other low-powered transmitter (five watts or less) to the BNC input connector. With RF applied to the amplifier input, tune the input and output capacitors C5 and C6 for maximum output on your meter. I was able to obtain 35 watts out. That completes the tune-up. Mount the cover on the chassis and you're ready to enjoy contacts that will hear you just as well as you hear them.

Conclusion

The Ten-Tec manual contains a troubleshooting guide that you probably won't need, but it's there, just in case. Its 26 pages include a circuit description and schematic diagram. Ten-Tec also has a limited warranty and a phone number for technical assistance should you need it. The back cover of the manual shows the resistor color codes and bits of other useful information.

I found this kit quite easy to assemble and had no problems — the amplifier performed as advertised and was fun to build. It doesn't have a large number of parts so it shouldn't overwhelm the new kit-builder. It completely solved my packet problem. It should also give the HT user quite a boost for the buck; no more, "Well, you're a little scratchy!" The only modification I would suggest is the addition of an ON–OFF switch. A Radio Shack™ illuminated switch mounted on the top side of the case will let you know when it's switched in or out, and allow you to run minimum power when high power is not required. Other than that, if you want to get your feet wet building a worthwhile project, I think you will enjoy building and using this 2-meter amplifier as much as I did, and you too can say, "...Oh yeah, I built that!"

You can get a free T-KIT Catalog by calling Ten-Tec at (423) 453-7172. T-KIT is a division of Ten-Tec Inc., 1185 Dolly Parton Parkway, Sevierville TN 37862-3710.

Tape-Wound Antennas
Continued from page 34

wave ground plane wires. These can be attached to the vertical using "T" fittings and 45-degree elbows.

It would be interesting to see some practical miniature beams built using TWAs. The effect of mutual coupling between elements would need to be looked into. However, TWAs would be ideal in constructing the high-performance but mechanically difficult W8JK type two-element driven beams with theoretical 5.2 dB gain over a dipole. This antenna can be set up based on resonance and symmetry.

Fig. 1 shows a suggested starting point. A typical design for 20 meters would have element lengths of 10 feet and a boom of 8 to 10 feet. Close-spaced beams like the above put severe demands on loss reduction since the radiation resistance is only a fraction of the radiation resistance of a single dipole. The TWA method is just the ticket. Rough calculations show that it should be possible to hold losses to about 1 dB with some end loading applied. This still leaves a net gain of 4 dB over a dipole, with full beam performance in all other aspects.

When capacitive end loading is applied, antenna efficiency will increase over calculated values, and would make an easy way of resonating an antenna wound a little too short. End loading can be applied by using plumbing Ts and placing copper foil on new short sections of pipe arranged at right angles to the dipole. These can then be soldered to the helical and adjusted for precise resonance, as shown in the photo for a 5-foot-long 14 MHz resonator. This is an extreme design with only about 50 kHz bandwidth. However, because of end loading it does achieve a more uniform current distribution and a relatively high radiation resistance which is estimated as about 2.5 ohms. Skin loss resistance is calculated as 1 ohm. Estimated efficiency is therefore still an astounding 71% (about 1.2 dB loss against a lossless dipole). Using a 3-inch pipe, losses could be halved but bandwidth would not significantly change.

A second method for enhancing radiation resistance and efficiency is by using wider tape in the middle of the dipole and transitioning to a smaller width toward the ends. This would be particularly effective with light capacitive loading. The current distribution would be flattened and resistive losses would be even lower.

A good rule of thumb is a physical tape length of one wavelength to achieve resonance for a uniformly loaded half-wave dipole. This rule gave very close results in all examples tried.

Multiband TWAs are also a possibility. The most straightforward approach would be to run two or more helical resonators in parallel, each wound for a particular frequency. The dipoles can be slightly turned between each other to avoid coupling, or be spaced a few inches apart. Unused dipoles simply become high Q chokes or capacitive elements. The antennas can be stacked using PVC plumbing components and cemented. It might be worthwhile to explore coaxial TWAs. Interaction between dipoles does not appear to create significant additional losses, a principle which can also be applied to the design of TWA multiband beams.

Remote tuning can be accomplished by moving an axial capacitive stub. The capacitive stub can be a flexible copper or steel wire wound and unwound on the inside center of the pipe. The wire is wound onto a metal pulley and shaft which is grounded to the center of the TWA. Little current flows so the arrangement is not very critical in terms of contact resistance. The PVC pipe provides a good seal to the environment. Either use a small motor or bring the tuning wire directly to the operating position. With a return spring, only a single mechanical control wire is needed. Teleflex type cables could be used. **Fig. 2** shows the functional arrangements. For small in-band changes, symmetry is not required. For symmetry and larger frequency changes, more elaborate tuning mechanisms can be devised.

The adhesive copper tape is readily available in major cities. I used 3M™ #1181. This tape has conductive adhesive. A non-conductive one is #1194. Both tapes have a 1.4 mil copper thickness. Skin depth at 14 MHz is 0.7 mils. Skin depth is inversely proportional to the square root of frequency so the tape could be used down to 7 MHz.

LETTERS
Continued from page 25

summer in New England.

The telecommunications industry is growing very fast, and our company is expanding rapidly. We are hoping to make a breakthrough into the PCS market, which looks like a $5 trillion industry. It will make cellular telephones obsolete, and revolutionize all telecommunications. It was a combination of education, experience, and amateur radio which helped me land this position. Reading *73* magazine back in Germany from 1976-78 convinced me to go on for my electrical engineering degree, and to continue with amateur radio. Using your tapes and study material helped me earn my Extra Class license in 18 months. And that was before Bash and without any prior amateur radio training. This electronic knowledge and my enthusiasm for technical writing made me into a salable commodity.

It is difficult for the industry to find any competent telecommunications engineers who also have the ability to write a coherent declarative sentence. I urge you to continue to editorialize on the necessity for technical people to improve their writing skills.

Most of us have read about the excellent educational system in Japan, where they teach integral calculus to seventh graders, and have superb scientific training. What most Westerners overlook is that Japanese secondary school students spend an average of three hours a week studying liberal arts, including expository writing, calligraphy, and interpretive dance and music. This liberal education, coupled with their superior technical education, has helped make their nation a leader. We would do well to emulate their example.

Again, I wish to express my gratitude. This is the best job I ever hoped to have. Your generosity and kindness helped to make it possible.

Aw, shucks...Wayne

Michael Nie KB8VMX. Wayne: I read your "Welcome Newcomers" piece with interest. Many amateur radio publications have printed op-ed pieces or articles bemoaning the lack of activity in the higher classes of licenses. The two words at the top of the page, "*Radio Fun*," sum it all up. Amateur radio is a hobby. It is supposed to be fun. I can only speak for myself, but I feel

Continued on page 82

NEVER SAY DIE

Continued from page 35

heart attack or stroke.

If you have any chronic illness, that's a powerful indication that you haven't been taking proper care of yourself. Lousy food, ingesting poisons, too little exercise and sun, too much stress. The route I'm promoting is one where your work will be so much fun that you'll never really think of it as work. Why do you think I publish a ham magazine? That's nirvana for a dedicated ham. I get to visit hams all around the world. I go on DXpeditions. I get to check out the latest ham gear. It's a life of adventure and fun.

When I published a music magazine my "work" involved listening to the new CD releases of my choice, visiting recording sessions almost anywhere, and so on. Talk about fun for a music-lover!

What is the most fun job that you could have? If you could live anywhere and do anything you wanted to make money, what would it be? I'm living on a farm in New Hampshire, where the air is always fresh, the water superb, and the taxes low. Exercising is a delight. Watching a whole bunch of deer feeding around the house is exciting. Shhh, please don't scare them away.

When you run your own business, if it's at all successful, your paycheck is whatever you want it to be. I paid myself over $500,000 a year for a while, but I got tired of paying the income taxes on all that. I didn't have any big personal need for money, nor the time or interest in taking care of it through investments. But then I've never done anything because it might make money. I do the things that are fun to do, that I think need to be done, and I try to do them so they don't *lose* money.

Sure, I want to get more subscribers for *73*, but that's because I want to try and help more readers have fun and learn things. If I can get you to elmer more new hams I'll have more readers and we'll all have a little more clout with the FCC when they start wanting to sell off our most valuable microwave channels. If I get more subscribers and thus attract more ads, you'll get a fatter magazine.

But it is nice to at least be able to buy the things you want without wondering how you can pay for them. Or to zip over to Paris or Hong Kong when you feel like it.

Well, that's enough for now. I don't want to totally ruin the sales of my $5 book *Making Money, A Beginner's Guide*. You now have the first lesson, which is to realize that you don't need a college education in some field to be successful. The next step is to figure out how you can learn what you need to know for a fun career at the lowest possible expense to yourself, and how to do it in the shortest time. When I started my first entrepreneurial business I was a millionaire within two years.

A baudy bunch

With most of the new TNCs including 9600 baud, I'd like to publish more info on this. For that matter, with Internet connections being considered slow at 14.4, there must be some interest in stepping up packet speeds. Let's (a) start doing it and (b) writing about it.

How about HF packet? What progress is being made in speeding it up and what are the problems involved? What do we have to do, start using the Internet for long-haul packet trunks?

How about Macs?

A letter from Jason Spitzer KD6HYB grumbled about the almost total PC and Windows orientation of ham computer stuff these days. Since I just bought a stupid PC so I could check out some of the stupid Windows CD-ROMs, I can only attribute the world's PC fixation to ignorance. Or misplaced thrift. Sure, Apple charged ridiculously high prices for their stuff. It made for great profit margins, crummy sales volumes, and a lousy market share. Now that the Apple share of the market has shrunk from 40% to around 10%, I can understand the revolving door to the management suite.

When Apple lowered prices their sales volume zoomed

Simply Portable

An easy way to operate in the field.

Peter A. Bergman NØBLX
3517 Estate Drive SW
Brainerd MN 56401

Often when planning portable operations, whether for Field Day or an actual emergency, we need to operate on the HF frequencies. Power for modern HF rigs isn't much of a problem, but the antenna can be. Some of the solutions that we've heard suggested include:

(1) Use a mobile antenna. It isn't as efficient as we might want, but...

(2) Hang a dipole between a couple of trees. There are no trees at the site but that's okay because the guy with the bow and arrow or whatever left it at home anyway...

(3) Put up a vertical and guy it to some stakes driven into the ground. Not a bad idea, unless your site happens to be in the middle of a frozen lake or a paved parking lot. Besides, someone is bound to trip over, or worse, for the antenna, *drive* over one of the guy ropes. There is also the problem of underground utilities which may not be as *far* underground as we might think.

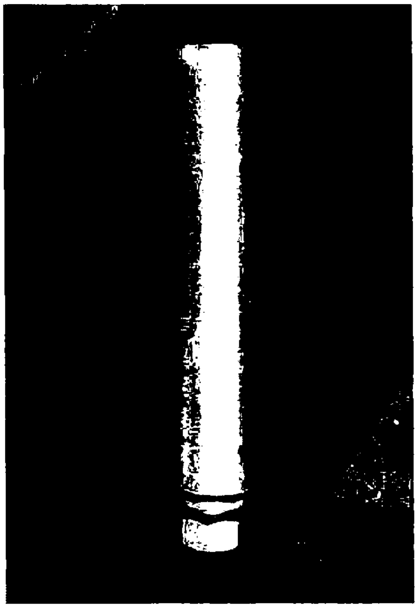

Photo A. *Neat and discreet. The finished mobile mount.*

"Armed with this gadget and a few wrenches, one person can have a 27-foot vertical out of the car, assembled, and erected in a very few minutes."

I liked the vertical idea. I use a ground-mounted vertical without much of a ground plane at home so I decided to see if I could figure out a way to mount it in the field. I wanted something that was solid, safe and easy for one person to put up. And I did *not* want to have to drive any stakes or dig any holes.

The solidest thing I'm likely to have with me in the field is my old station wagon. Unfortunately, the solidest part of my old station wagon is the trailer hitch. After a bit of head scratching I came up with the simple solution. The junk box provided a nine-inch length of 1-5/8" o.d. pipe, the hardware store provided a 3/4" by 3-1/2" bolt and two matching nuts. Our club VP, KAØJSW, did the welding. The photos and **Fig. 1** show that this *is* the simple solution. Armed with this gadget and a few wrenches, one person can have a 27-foot vertical out of the car, assembled, and erected in a very few minutes. Even if you plan to operate from inside the car, where you might normally use a mobile antenna, the vertical should prove to be more efficient. After watching me set up at a recent hamfest, several people were sufficiently impressed to say they planned to make a similar mount for their "get-n-go" kit. "Just in case." If the junk box ever produces a 3- or 4-foot piece of pipe I may make a taller mount to get more of the antenna clear of the car body, but for now, this is simple. I may also weld some kind of crank or handle on the 3/4-inch mounting nut to avoid having to carry around a heavy, expensive wrench.

Photo B. *Locked on and ready to rock 'n roll!*

HAMS WITH CLASS

Where In The World Are We?

Carole Perry WB2MGP
Media Mentors Inc.
P.O. Box 131646
Staten Island NY 10313-0006

The world comes alive in the classroom with amateur radio! My radio courses for 6th, 7th, and 8th graders give me the opportunity to teach geography skills on a need-to-know basis. There is nothing more natural than locating a spot on the map to discover where the voice you're hearing is coming from.

Geography skills are an intrinsic part of the bonus package that young hams get every time they make a contact out of their local area. The youngsters benefit in so many ways by becoming more geographically literate. Impromptu discussions take off after the simplest DX contact. For example, one of the best units on Central America came about after a contact with a ham in Belize.

Discussions about history, economics, government, climate, and culture went on for days in my class. I had the children designing travel brochures and creating bumper stickers. One of the cleverest slogans was, "Without geography, you're nowhere. But with geography, you're everywhere."

My suggestion to any teacher incorporating radio into class lessons is to coordinate lesson goals with a Social Studies teacher. Your school administrators will love the idea of the "team" approach to teaching, the Social Studies teacher will become enchanted with the idea of speaking directly to people from around the world, and the children, of course, will have fun while they're learning.

Every year I add at least three new resources to my Geography multi-media center. Here are some good ones that might be worth your while to pursue:

1. *Geotopia*- This booklet allows students to create their own imaginary country, including climate, crops, culture, physical features, and more. *Geotopia* is published by USA Today Educational Programs. Student copies are 35 cents each. Free teachers' supplemental materials are included. For more information call 800-USA-0001.

2. *Somewhere In the World Right Now* - Through this story book, take a look at what individuals are doing simultaneously in different time zones around the world. Written by Stacey Schuett, this 1995 release is published by Knopf for $16.00. (ISBN 0-679-8537-3)

3. *Cross-country USA* - Diatech Software has designed this elementary level software. The program, available for both PC and Mac, introduces children to U.S. geography. School editions, lab packs, and site license versions are available. For a free demo disk, contact Brian Selstedt at 800-665-0667.

4. *Kid's PACK* and *Teen PACK* - Zero Population Growth has put out two new programs for middle school and teen students. PACK stands for Population Awareness Campaign Kits. They include hands-on activities in a colorful format. These free programs can be ordered in bulk by teachers. Contact Pamela Wasserman, Director, Population Education Program, ZPG, 1400 Sixteenth St. NW., Washington DC. 20036.

5. *Material World* - Software lets you experience local customs, indigenous music, prized possessions, and the laughter and tears of people around the world by looking at the lives of thirty typical average families. Families in Kuwait, Thailand, Mali, and Sarajevo are but a few viewed. Software comes in both Mac and PC versions. For more information contact StarPress Multimedia at 303 Sacramento Street, 2nd floor, San Francisco CA 94111 or call 800-782-7944.

Remember, the most important thing you want to do is to convey a sense of genuine excitement about reaching out to other people all over the world through amateur radio. Have fun!

***Photo B**. Some of our best Geography projects have come about after a DX.*

***Photo A**. Children enjoy locating the source of the radio voice.*

73 Review

The DVR-1 Digital Voice Recorder

Bill Clarke WA4BLC
764 Altamont Voorheesville Road
Altamont NY 12009

Hamtronics' easy-to-build DVR-1 Digital Voice Recorder kit was initially designed for IDer use in repeaters. The recorder does, however, have several other applications for the ham as an adjunct for SSB operation. Here's an introduction to the DVR-1, as a kit, and some generic connection information for its use with SSB transceivers.

The DVR-1 is a digital audio recorder that allows 20 seconds of recording time; you can transmit a previously recorded message at the press of a button, record incoming audio for instant playback, or retransmit previously received audio.

Why would you want to transmit a previously recorded message? Just think of how many times you might say "CQ CONTEST...CQ CONTEST...CQ CONTEST" during long hours of operation. Save your voice!

Heard a weak one and didn't quite catch the call? Press playback as many times as you need and listen, over and over, until you figure it out. That was a 59 report, wasn't it?

Ever been asked by the local microphone adjuster, "How's my signal now?" Just record the received audio and transmit the playback. Let the sender be the judge!

The DVR-1 can be bought as a kit or as an assembled-and-tested printed circuit board ready to connect with your station. I recommend the kit, as it will save you about forty dollars and will only take an hour to assemble.

The kit I assembled uses sockets for the ICs, and has ample space for all components. The circuit board is double-sided and made of high quality Fiberglas™. The layout is easy to work with; the assembly instructions are given as steps, and warnings are clearly marked for components that must be oriented in a specific manner, such as diodes.

Be sure you use a low wattage soldering iron during assembly. My personal favorite soldering tool for small projects is the Isotip rechargeable with a fine tip, available from MCM Electronics. It is lightweight, easy to handle, and is a low wattage unit that will not harm the foil on the printed circuit board. Use solder sparingly and carefully clean away any solder bridges or globs of flux.

The completed DVR-1 is meant to be installed inside a repeater; however, for use as a station adjunct for SSB, you will need a project box. Project boxes are available from Hamtronics, as seen in their catalog, or from Radio Shack™.

Use a project box large enough to hold the DVR-1 plus a few panel controls on the front and/or top and connection points on the rear. You will need rubber feet for the bottom and labels for the controls.

I chose to make my installation as simple and easy to use as possible. The project box I used was the TP43 (2.5 x 5 x 5 inches) from Hamtronics. This is a little larger than necessary, but it sits firmly on my desk (this project doesn't weigh very much). The DVR-1 circuit board was installed using standoffs and screws. It could as easily be mounted using silicone glue and short pieces of doweling for standoffs.

I installed my controls on the top of the box, so I wouldn't have to play tag with the box each time I pushed a button. The controls consist of an on/off switch, a momentary contact push-button for RECORD and the same for PLAYBACK. There are two toggle switches—one to select audio input source (internal mike or receiver audio) and the other to select audio output to the transmitter's mike line or to an external speaker and control PTT switching. Internally, I installed a small 5V DC relay to key the PTT line when I wanted audio playback to be transmitted.

On the front panel is a 12V DC pilot light and a one-inch hole to allow use of the DVR-1's built-in microphone. The mike could easily be mounted on the front. On the rear panel of the project box are four RCA jacks; for 12V DC power, audio input from the receiver, audio output to the transmitter, and the transmitter's PTT line. A pair of insulated screw terminals are used for external speaker connection. The internal connections are made to the DVR-1 circuit board per instructions in the manual.

Hamtronics provides a thorough manual with the DVR-1. It shows the method of construction and how to connect simple divider circuits for audio input and output, fully explains operational theory, and gives examples of circuit enhancements.

An interface circuit was built for audio input from the receiver, the small relay was connected to a pad that provides +5V DC during playback (normally open contacts actuate the PTT line), and the playback audio connected to the transceiver's mike input line. The RECORD and PLAYBACK switches are tapped into the DVR-1 circuit board in parallel with the existing switches.

Check the operating manual for your particular transceiver for details about circuit interfacing and connection points. Do this carefully to assure proper connections — so no damage to either device occurs. 12V DC power can be taken from your station power supply or tapped from a transceiver.

To check the DVR-1's operation, switch to the internal mike, press RECORD and speak. Using speaker output, press PLAYBACK. You should hear what you just recorded.

Receive audio is easy to interface with the DVR-1. I used a Y-plug adapter at the transceiver's external speaker jack, sending one side of the audio to the external receiver speaker and the other to the DVR-1. The constant level audio output of a transceiver could also be used, if available. Some adjustment of

the divider circuit you built inside the project box will be necessary to prevent overdriving the DVR-1. Recording is done by pushing the RECORD button and playback by pushing the PLAYBACK button. Playback will be through the speaker connected to the screw terminals on the rear of the project box.

To send a recorded message, such as a CQ, switch the audio output to the mike line (which also activates the PTT line on my unit). Record a message as you previously did. Press PLAYBACK, which will key the transmitter and play the message through the transmitter's mike circuit. Adjust output level as necessary. Recording off-the-air and instant playback are merely combinations of these two operations.

Other configuration options

Instructions are given in the operations manual for more complex setups, such as splitting the 20-second recording time into smaller time blocks. This allows the choice of more than one prerecorded message to be transmitted, by operator selection—an ideal setup for contesting.

Beacon ID can easily be accommodated using the DVR-1. The internal timing circuit can be used to activate the transmitter and play back the recorded message. The timing circuit can be changed to provide any desired timing interval.

The DVR-1 can be used anywhere instant audio recording and playback is needed, or where there is a requirement for playback of messages at prescribed time intervals. I can see applications in stores, warehouses, and in theft/intrusion alarm systems.

The Hamtronics DVR-1 is available for $59 in kit form or $99 assembled and tested. Contact: Hamtronics, 65 Moul Road, Hilton NY 14468-9535. Phone (716)392-9430 or Fax (716)392-9420. Ask for their catalog—it has lots of nice projects for radio hobbyists. 73

Mail call!

Well, the mail has been accumulating, so it's time to dig in and answer some questions. Before I do, though, I want to add something to the series on repairing computer monitors that we wrapped up in the April issue.

I stated that just about any horizontal output transistor could be used in most monitors. For the most part, that's true, but there is one consideration I forgot to mention: Some transistors have integral damper diodes and some don't, and never the twain should mix.

What's a damper diode? If you look at a TV schematic, you'll see that the horizontal output transistor pulls current through the low-voltage, high-current side of the flyback transformer. Even on the low-voltage side, though, there could be anywhere from 20 to 100 or more volts. The inductive spike which occurs when the transformer's field collapses can be tremendous. It can induce "ringing" in the coil, resulting in a disturbance in the horizontal scan. It can even be enough to damage the transistor. So, all TVs always have a damper diode which is reverse-connected across the transistor and damps out the ringing. In the tube days, there was a damper tube. When solid-state parts took over, a fast-recovery diode did the job. These days, the damper may still be a diode on the board, but it can also be inside the horizontal output transistor itself.

For instance, a 2SC3486 doesn't have a diode, while a 2SC3893A does. If the original transistor had a diode, you must use a replacement that has one, too. Can you replace a non-diode transistor with one that has the diode? Logic suggests that having two diodes in parallel (which is what you'd wind up with, because there'd also be one on the board somewhere) should be OK. In all fairness, though, I haven't actually tried it. To be safe, just use a compatible transistor with the same diode arrangement.

Let's dig into the ol' mail bag!

Dear Kaboom,

I've always had a dream of building an HF amplifier from transistors. I'd like to construct an amp using 24 2879s. I figure 24 120-watt transistors would give me a sturdy 1.5-kilowatt amp that would loaf along quite nicely, yet I can't find any construction articles or books for making such a beast. Where is the information? Who might I ask? Where do I look?

Signed,
Warm Up The Iron

Dear Warm,

Good question! There are a couple of commercially available, solid-state amps, but the technology has not yet become commonplace. I suspect it's mostly due to cost. Why should a solid-state amp cost so much more than a tube amp of equivalent power output? Well, you can get one heck of a lot more power from a single tube than from a single transistor. So, you have to use a lot of transistors, as you pointed out, in order to get the kind of output you could obtain from a tube or two. Really, it isn't the cost of the transistors themselves (although that's not insignificant) which makes the amp so expensive. Rather, it's all that coupling! How the heck are you going to couple the inputs and outputs of 24 active elements so that they all stay in phase and share power equally, especially at radio frequencies? It can be done, but it isn't easy, and it requires lots of windings on a big RF transformer, and plenty of heat sinks and equalizing resistors. Also, provision has to be made for enough isolation between the transistors to avoid a mutual disaster should one of them short out.

Then there's the matter of the power supply. The high-voltage, medium-current power used by tubes is fairly easy to obtain from ordinary 120- or 220-volt wall current. But where are you going to get, say, 14 or 28 volts at 100 to 150 amps? That's a lot of current, and it'll require not only a very big power supply — even with a switcher, we're talking some iron — but also extremely thick conductors to the transistors or whatever feeds them. You just can't pump that kind of current through #14 wire!

Power MOSFET transistors are easing the problem somewhat, because they can work at higher voltages (and thus lower currents), and can produce a fair amount of power per transistor, meaning you have to use fewer of them. So far, though, nobody is producing transistors with the power output of even a smallish tube like the 3-500Z.

If you really want to build a legal-limit, solid-state amp, go for it, but be aware you're facing a difficult task. I don't know where to tell you to turn for construction information, but if any of you gentle readers can advise, I'll publish the info here in the column.

You also mentioned you might like to build a tube amp. For that, the *ARRL Handbook* should be quite helpful. True, it's not a compilation of amp circuits, but there should be enough in there to get you going, and you can develop your own modifications to make the amp into what you want. I wish you the best of luck in your amplifier projects.

Dear Kaboom,

The LCD on my ICOM IC-02AT conked out. It is blackened about 90 percent, but I can't see any other physical damage. Could something be wrong with the radio's circuitry? The rig works fine otherwise. Can I replace the display? What is involved with that?

Signed,
Squinting

Dear Squint,

No, there's nothing wrong with your radio's circuitry. I've seen this happen before, generally on older radios. In fact, my car stereo's display is slowly going the same way. It's caused by loss of the seal on the edges of the display, causing the two glass plates to separate slightly. That lets the liquid-crystal material flow, leaving areas where there is none. The result is a black display, even when the radio is off. The only fix is to replace it. If you're handy at taking equipment of this scale apart, you should be able to replace the LCD fairly easily. Many LCDs are held in place only with pressure, either from a bracket attached to the PC board, or by the radio's case. Contact is made via a special conductive rubber ribbon. Other displays have regular solder contacts which will have to be desoldered from the board. I don't know which method the 02AT uses, so you'll have to open it up to find out. As for obtaining the display, you'll need to order it from ICOM; such displays are all custom-made for different radios, and you can't get one at your local surplus house. By the way, if you find any of the liquid-crystal material leaking out from the display, *don't touch it—it's poisonous.*

Dear Kaboom,

I know this is a little bit off the ham subject, but the CD-ROM drive in my ham shack computer is acting up in a strange way. It has trouble reading a disk, especially at the beginning. Sometimes it'll read it, sometimes it'll just give up. It won't read some disks at all, while others usually work. It seems to be getting worse. Any ideas?

Signed,
No Drive

Dear Drive,

If you've been using the drive in a very dusty environment, or you're a (gasp) smoker, it's possible that the lens has become dirty. There are special lens cleaning disks which can clean it for you. I suspect, though, that the real problem is that the optical pickup head in the drive is failing. I've seen many audio players with the problem you describe. Unlike LEDs, laser diodes have a finite life; they gradually get dimmer and dimmer until there's not enough light for the player to

see the disk. Because reflectivity of CDs isn't perfectly uniform, some disks work better than others when the beam is marginal. Eventually, it'll get so dim that the player will cease to function. Although it is possible to replace the head, it's rarely worth it, because the part costs more than an entire new player! Besides, alignment is tricky; you really have to know what you're doing, and an oscilloscope is mandatory. I think you need a new drive.

Well, that's it for this month. Until next time, 73 de KB1UM. 73

Test equipment and frequency counters

Last month I described some of the methods used to form an interest group for the VHF/UHF/SHF frequency bands. I described several of the steps our group went through, in order to assist you in putting together a similar group. This month, let's get into some of the tougher issues, like what test equipment is needed to perform modifications and tune up equipment. This step is to further assist your group's technical needs. Having some basic microwave test equipment available is crucial.

"We are starting to see inexpensive frequency counters good to 2 GHz."

With any microwave group or society formed, there must be a source of test equipment available to help solve the technical problems of the group. For those of us who started our amateur operations with much simpler modes, and even with vacuum tubes, test equipment was just as viable then as it is today. In those early days test equipment was limited to Eico or Heathkit commercial kits of o-scopes, signal generators, voltmeters, and various SWR and assorted station accessories. Also available was equipment from military surplus or, more properly, World War II and later surplus material.

I remember many days of converting ARC-5 transmitters that used 1625 tubes in the final for CW operation on 80 and 40 meters (a 1625 is a military version of a tube familiar to many old-timers, the 807). However, I don't want to get hung up on converting ARC-5s as I reminisce on the meager equipment collected at that time to test and make functional early projects (I would really like to find a clean ARC-5 for Memory Lane). The test and alignment equipment needed today is more exotic and a far cry from our early frequency meters.

Frequency counters

It doesn't take much to remember a frequency counter that counted up to 1 MHz (HP-523), and a much sought after frequency counter that made it to 10 MHz directly and ultimately to 500 MHz with appropriate plug-in converters. Did I mention that the HP-523, weighing in at 60 pounds and made for rack-mount, sported several handles to allow moving it? Did I have these units in my shack in the 60s? Yes, plus a small cart to move them.

We have come a long way in test equipment development, not only in military models but in civilian models as well. We are starting to see inexpensive frequency counters good to 2 GHz, and to hear about some models on the drawing board good to better than 10 GHz. Surplus counter types that go to 50 to 300 MHz and have plug-ins to extend that range up to 18 GHz are now commonly available. There are direct-reading counters that count to 18 GHz. Needless to say, these are some of the more expensive counters available on the surplus market.

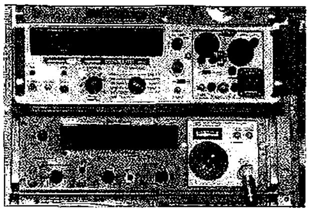

Photo A. Two older HP frequency counters: the Systron Downer 1037 counter with a transfer oscillator that goes to 18 GHz (top unit); and the author's HP-5245 workbench workhorse with a 3 to 12.4 GHz plug-in.

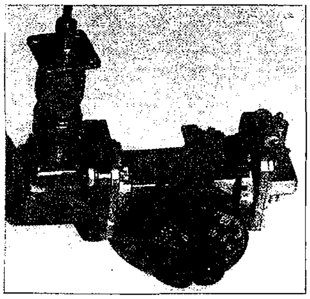

Photo B. The author's 10 GHz Gunn oscillator (10 mW) waveguide attenuator and coax transition, forming a 10 GHz signal generator for bench tests.

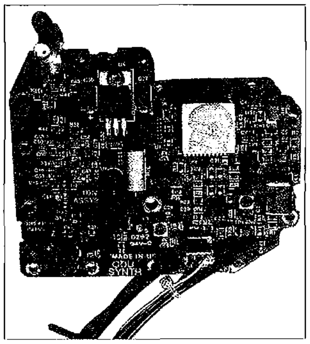

Photo C. A Qualcomm phase-locked loop VCO-controlled synthesizer. This functions one point frequency between 2 to approximately 3 GHz, but normally resides near 2.6 GHz. It can be pin-to-pin programmed, or you can use an IBM bus.

There are several different surplus choices that can be taken advantage of when you locate them. What I want to do this month is give you some guidelines on what surplus frequency counters are available today and cover some of their capabilities. Also, I want to discuss some of the newest amateur market frequency counters that are now being sold. Coverage will be limited to ease of operation, frequency coverage, frequency accuracy and, finally, cost, to give you some benchmarks to help you make up your own mind.

What are the main differences between surplus and new frequency counters? Mostly, weight and cost. Surplus counters are typically heavy and seem to cost more. Why consider a heavy and more costly counter vs. a newer, smaller, battery-operated, less costly one? To answer this question you have to ask yourself a question: What do you expect from a counter? What frequency ranges are required and to what accuracy must this measurement be relied upon?

The answer: If your frequency measurement requirements do not go over 2 GHz and the accuracy needed is average, I suggest purchasing a small battery-operated counter. There are many different models available from Startek, Ramsey, Digimax, Optoelectronics, and many others that will fill the bill very nicely. The Startek Model ATH-50 is quite nice and has a top frequency limit of 2.8 GHz (2,800 MHz) and an LED bar graph showing signal level. All those features for only $339—quite a deal.

The frequency accuracy of most of these frequency counters is in the order of 1 ppm. What that means is 1 hertz of possible error for every megahertz of frequency being measured. If we were to measure a 2 meter HT, for instance, our possible error at 2 meters would be 150 hertz of uncertainty. Most manufacturers make a high accuracy time base that is an extra add-on feature, making their frequency counters more accurate. For instance, Startek's option #HST-15 costs $125 extra, and its high accuracy "Temperature Controlled Crystal Oscillator" (TCXO) time base upgrade increases accuracy to ± .2 ppm.

Operation with a TCXO is transparent to you but allows the internal crystal reference to the counter to be controlled by a higher-accuracy time base, increasing accuracy in your measurements. Going to a .2 ppm time base TCXO oscillator would reduce errors at 2 meter (150 MHz) measurements to 30 hertz.

In practice, it's not quite that pure because the error is not a perfect 150 hertz or so. The uncertainty factor is a ratio somewhere around this number. It could be high or low depending on when the last calibration was done using WWV or some other calibrating method.

Now enter the microwave scenario. How do you measure frequencies over the range of the portable counter? Well, there are several methods, one being a surplus frequency converter (the HP-2360). This unit mixes a known harmonic whose fundamental frequency is in the 200 to 300 MHz range of the unknown microwave frequency. Make two to three measurements to find a harmonic that is nearly 60 MHz apart. After you determine what two fundamental frequencies, multiplied by the harmonic number, produce this 60 MHz separation you will know the microwave frequency exactly. The 60 MHz separation is due to one frequency going 30 MHz high and the other going 30 MHz low, resulting in a difference of 60 MHz. The method is a little cumbersome but does work.

Other frequency counters to look for in surplus are Systron Downer and Hewlett Packard units. I happen to have, for test evaluation, both the Systron Downer and Hewlett Packard counters. These all run from AC mains and are a little on the heavy side. **Photo A** shows both counters with their respective microwave frequency converters (plug-ins) in place. I like the Systron Downer as it can be set up to generate a weak signal on a frequency for marker use, while the HP does not leak a sample of the harmonic through the converter front end.

What makes these large commercial frequency counters still popular? The accuracy is quite a bit better and the frequency capabilities can go to 12.4 or even 18 GHz with readily available plug-in converters. Frequency accuracy is tighter as this type of counter uses an internal oven-controlled "high accuracy standard." How accurate? Using a counter with an accuracy of 1 ppm would give a 10 kHz possible error in your frequency at 10 GHz. Now, if you're looking for weak signals, this is a wobble in your cog and needs to be addressed.

Normally these units have an oven-controlled crystal oscillator that can be calibrated to a few parts in 10 to the 8th power—that's .01 ppm. Now, with the appropriate converter plug-in attached into the counter we will measure a 10.368 MHz frequency with a possible error of 100 hertz. With a few extra tricks it gets even better when you connect to an external frequency standard capable of higher accuracy. My external master standard (really my garage standard) is an FEI-10A capable of producing a 1 MHz oscillator which is accurate to .0001 hertz at 1 MHz. That is the same as .0001 ppm, and it's not worth figuring out the error, as that's about as good as it gets in amateur circles.

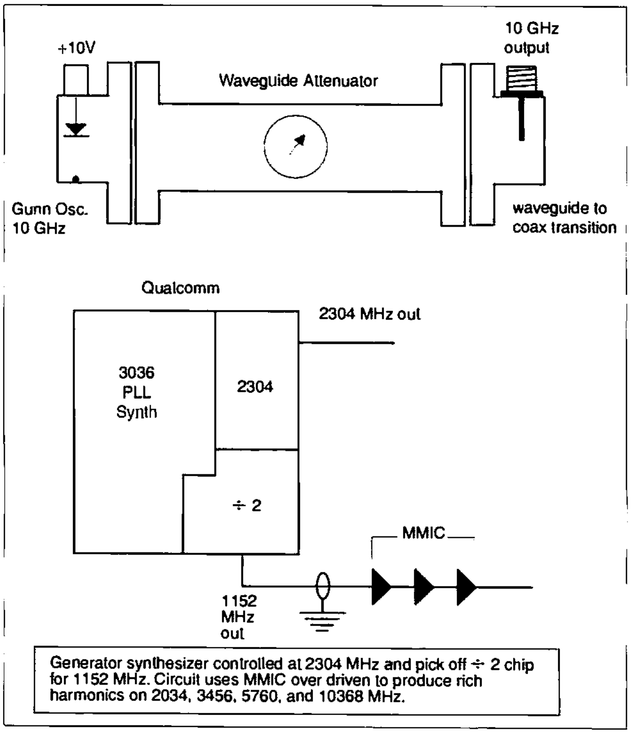

Fig. 1. *Schematic of a simple microwave test generator.*

"The most important piece of test equipment is the microwave power meter."

Now comes the tough question: How do you convince someone that their calibrations made with WWV at 10 MHz have little to compare with the measurements you just made with your Garage Standard? Measurements based on WWV accuracies are good to about .1 to .01 ppm at best, due to the Doppler effect. Doppler shift affects the path over which the highly accurate clock at WWV (the source) must travel before you receive it (2.5 MHz and up). Sure, at the source it's accurate to .000001 or better, but the accuracy changes at your receiver due to the transmission path Doppler effect on the low to high MHz frequency bands.

A very high accuracy reproduction of WWVB can be received at 60 kHz due to minimal Doppler problems at this low frequency. This is the same method that I, and calibration labs, use. This is the "traceable path from your standard to WWVB's national standard when so calibrated." Well, so much for counters and accuracy. Let's get on to what other test equipment is essential for microwave tinkering.

Power meters

The most important piece of test equipment that should be in any modest ham microwave workbench is the microwave power meter. This piece of test equipment is the single most used item in my shack's workbench, along with a set of attenuators to extend its range to higher power. I have written several articles on both the General Radio and Hewlett Packard power meters and don't express a preference. The most important thing is to have some means of discerning microwave power at very low levels in order to be able to perform modifications and circuit stripline tuning. Sure, a spectrum analyzer is very nice in this application as it will show you what is actually going on. For the broad picture the spectrum analyzer is paramount. But for fine adjustment response the microwave power meter will show you .1 dB increases with ease where .5 dB increases are about the best you can see on a spectrum analyzer available in the amateur's grasp. New spectrum analyzers with digital readout are available with better readout, but (gasp) the *price!*

Other test equipment

What items would I place on a shopping list to add after the power meter? I would suggest a simple test generator and attenuator setup to function at your desired test frequency so that you would be able to generate and detect the frequency of interest. The frequency generator doesn't need to be a full relay rack signal generator; it can be a simple free running or synthesized source that can be controlled. By that I mean a shielded source and one that is somewhat reliable, like the Gunn oscillator/waveguide attenuator and coaxial transition used for 10 GHz test configurations. Keep it simple: high accuracy generators are nice but not necessary. See **Fig. 1 and Photo B** for my 10 GHz generator.

Next, to improve your calibration and test agility pick up some coaxial attenuators of various values of dB loss. These will be necessary to use in conjunction with your power meter to prevent burnout of the sensitive power meter head. These heads will usually

accept a maximum of +10 dB. Power levels above this can burn them out and they're not repairable. Remember here that 100 mW (.1 watt) is +20 dB and this level is easily reached in most circuits. Use a 10 to 20 dB protection pad on the input of your power meter for the safety of your power meter head.

A new twist on the test equipment angle is that very modern circuitry is making high-tech test equipment obsolete. Well, this is true to some extent in that recent advances in frequency control and receiver and transceiver circuitry are starting to make these products look more like computers than the products they really are. An example of this is the vertical hold control on your television receiver. Early sets had both vertical and horizontal controls accessible for your adjustment. Try to find one today; they use zero crossing detectors, instead of the earlier consumer controls, to lock up the picture. So it is with microwave circuitry in some cases.

Yes, you still need a generator to provide a test signal to tune stripline circuitry. The microwave power meter is required to give you "eyes" on power changes on tune-up or modification. Attenuators are required to limit power to acceptable levels for protecting the instrument. Frequency measurement and accuracy to your desired limits provide an additional window to give you a comfort zone in test equipment adjustment and modification ease.

With some of the newer frequency-controlled synthesizers in use today to generate a local oscillator for microwave down converting, high accuracy microwave counters are needed for reassurance of actual frequency. In most cases using these modern synthesizer components, once phase-lock is obtained you are there. Specifics: Our group uses a surplus synthesizer that uses a Qualcomm 3036 phase-locked loop chip that functions directly at 1.6 GHz (**Photo C**). All frequency generation is by VCO in the 2 to 3 GHz range. This chip (3036) can be set up to be programmed from an IBM bus or for pin-for-pin programming of frequency (**Fig.2**).

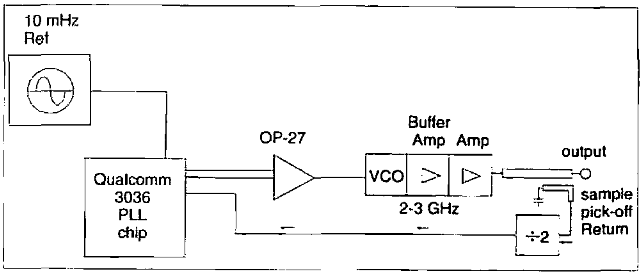

Fig. 2. Block diagram of a Qualcomm 3036 oscillator. This unit can be reprogrammed to 2556 MHz for 10 GHz operation, 2304 MHz for beacon work, or even 2160 MHz for .3 GHz operation. It's quite a versatile PLL controlled VCO.

Now, with this synthesizer you could program 2556 MHz times four to provide LO injection at 10 GHz. Frequency combinations are endless. For example, 2160 at LO for 2304 with an IF frequency of 144 MHz. 2304 could be programmed for a test source or even a beacon on that frequency. If you program 2304 there is an on-board frequency divider (I said earlier that the 3036 only worked to 1.6 GHz, remember?). Dividing that by two, it could be used to pick off 1152 MHz. This one frequency and its harmonics are the mainsail of all microwave generators.

If you multiply 1152 times 2, 3, 5 and 9 you get the standard microwave frequencies of x 2 = 2304, x 3 = 3456, x 5 = 5760 and x 9 = 10368 MHz. This is nice frequency multiplication for simple generator circuits. Just overdrive an MMIC amplifier to accent the harmonics and use the signals for your version of the Gunn oscillator, not only at 10 GHz but on all the other ham bands below 10 GHz except 1296 MHz. Well, that can be handled also. If you mix in 144 MHz it will produce 1296 MHz as one of its products.

How stable is this synthesizer? If the wobble in your main frequency cog is limited to a 10 MHz TCXO oscillator, that is capable of maintaining .01 to .1 hertz at 10 MHz. In actual use this wobble works out to be less than SSB bandwidth errors at 10 GHz (a few hundred hertz maximum error).

Conclusions

What specific test equipment would I recommend? Well, I would like each of you to have a complete lab, but knowing this is not always possible I would suggest a group pool of test equipment. With several interested amateurs each contributing, you just might start a microwave interest group of your own. Check out the Startek ATH-50, or the Digimax or Optoelectronics frequency counters. They will allow you to operate to over 2 GHz with sufficient accuracy extrapolated out to 10 GHz. Remember: It's not extreme accuracy that is required if your signals can be found inside the SSB or FM bandwidth required for normal operation. Then it's just: Readjust the RIT control for clarity. Exact sometimes gets boring.

From the junk box side of things, I have picked up some surplus items you might be interested in. I have a quantity of 15 mW Class III HeNe laser heads manufactured by Melles Griot. They require a power supply and measure 7 to 8 mW output with my test arrangement. Also, I have picked up several LORAN-C complete PC board receivers. The lasers are $45 postpaid, and the LORAN-C receivers are $15 each or two for $25 postpaid. At these prices for Loran-C they're untested pulls. I have tested 10 units and had only one not function fully. I do have a batch of units for parts, great 100 kHz circuitry and coils. If you want one with your order let me know and I will throw it in for postage costs.

As always, I will be glad to answer questions pertaining to this and other amateur related topics. Please send an SASE or drop me a line on the Internet. My address on the Internet is clhough@aol.com. 73 Chuck WB6IGP.

NEVER SAY DIE

Continued from page 47

upwards, and all those magnificent profits which had been supporting a Parkinson's Law of ever-increasing corporate body count disappeared. They probably could get rid of half of the staff and be able to respond to the market better. They also might not get stuck with turkeys like Scully's Newton.

I'm up to here in Macs, which are the most practical computers for publishing. So, like Spitzer, I'd like to see a spotlight on Macs for packet and other ham applications. It might even be worth publishing a column. How about it? I'd like to hear from a Mac expert interested in helping out.

Ham jailed

We really need to push the ARRL to get the FCC to change our rules so it is easier to delicense the rotten apples that get through the simple screening process. A case in point is the recent jailing of Ronald Ames WB6RSD, who has been a royal pain in the ass to his fellow hams for several years. Heck, the legal actions have been going on for over two years. The judge found Ames to be "arrogant, stubborn, and closed-minded." He put Ames in the slammer for 15 days and fined him $3,000.

There should be some way for us to drain our ham sewers, like that bunch of idiots on 14,313. We should have a way to get rid of frequency coordinators who favor friends, jammers, and so on. Old-timers will remember Max W2BIB, who devoted much of his hamming time to jamming emergency traffic. He finally died. And then there was W2OY, who did little to make hamming fun.

Fame

A Silent Key announcement from Australia for Syd Molen VK2SG reminded me of a recent editorial in which I pleaded with you to make us all aware of hams who have been doing good works. Syd, it turns out, was one heck of an RTTY pioneer—and I never heard of him before! As the publisher, starting in 1951, of an RTTY magazine, I knew all of the American RTTY pioneers...John Williams W2BFD, Merrill Swan W6AEE, Bob

HAMSATS

Amateur Radio Via Satellites

Andy MacAllister WA5ZIB
14714 Knights Way Drive
Houston TX 77083

If you can't hear them, you can't work them. This simple premise is common to all facets of two-way radio. For the amateur satellite enthusiast, weak-signal operation is the norm. Satellites have limited power budgets. With the exceptions of the high elliptical-orbit satellites like AMSAT-OSCAR-10 and AMSAT-OSCAR-13, hamsats transmit less than 10 watts to very simple antennas. On the ground, good antennas, sensitive receive gear, and quality cable to connect them are required.

On the transmit side, the same rules apply. A poor antenna with inadequate feedline will require more power from the transmitter to get a signal up to the satellite. More power means more money for an amplifier.

Most hams shop for antennas with high gain, receivers with good sensitivity and transmitter systems with adequate power for the earth-to-space link for their satellite stations. Many hams will try to save money on the feedline. If the cable is not correct for the job, the receive and transmit signals are low, enthusiasm fades, and another satellite station goes silent.

The rig-to-antenna connection

If money were not a concern, multiple runs of 7/8-inch diameter Andrew Corporation Heliax would do well for all of the current satellite bands from HF through SHF. Five 100-foot runs with new cable and connectors would cost about $750 per run for a total of $3,750. Surplus or used cable and connectors would cost a lot less, but other considerations take over. A bundle of cables that large would be hard to position and almost impossible to connect to rotatable antennas. Jumpers and additional connectors would be needed. Some interesting explanations might also be in order if the radios were in homes and holes had to be drilled for the large feedlines.

Putting together a quality, yet cost-effective, feedline configuration requires some careful study and a few trade-offs. While the Heliax would be great for a long run at 1.2 GHz, it would be serious overkill at 21 or 29 MHz.

With little previous knowledge of coaxial cables and connectors, most newcomers to the predominantly VHF and UHF realm of the amateur radio satellites find the options daunting. One look at a Belden catalog of wire and cable or an Amphenol RF and microwave connector listing can lead to quick confusion. For most antenna installations using frequencies from 450 MHz and down, a few simple guidelines can help.

Coax

For short coax runs (less than 50 feet), a premium-grade, brand name, 50-ohm RG-8/U type coax will do the job. The "RG" is a military designation for coaxial cable and the "U" means "general utility". For outdoor use, RG-213/U (Belden part number 8267) is an excellent choice. It has reasonable loss characteristics, 97 percent shield coverage and a non-contaminating PVC (polyvinyl chloride) jacket that will survive exposure to the sun and weather much longer than others.

Loss characteristics are usually given in dB (decibels) per 100 feet for various frequencies that may be used through the cable. The Belden type 8267 exhibits a loss of 1.9 dB per 100 feet at 100 MHz, 4.1 dB at 400 MHz and 8.0 dB at 1 GHz. This means that with a transmitter running 100 watts on 100 MHz at one end of the 100-foot cable, the 1.9 dB loss would attenuate 35 percent of the signal, or 35 watts. Only 65 watts would make it out the other end. The rest would be absorbed in the cable. At 400 MHz, the same 100 feet of cable would lose 61 percent of the signal, and at 1 GHz the cable would lose 84 percent of the signal. At the end of the cable, only 16 watts of the original 100 watts would be available.

The insulation between the center conductor and the outer shield is solid polyethylene for the Belden type 8267. The nominal velocity factor due to the use of solid polyethylene as a dielectric is 0.66. This value is the transmission speed of RF energy in a length of cable compared to speed in free space. It is usually expressed as a percentage.

Belden RG-8-AU (P/N 9251) has almost identical specifications, while the RG-8/U (P/N 8237) uses a slightly different inner insulation and does not have the non-contaminating jacket. Outside use will therefore limit the useful lifetime of the RG-8/U. Another favorite due to favorable loss characteristics and reasonable cost is the Belden 8214 coax. It is an RG-8/U *type* cable. It has the standard PVC jacket, but with a cellular polyethylene inner insulator that increases the velocity factor to 0.78. It is sometimes called RG-8 "foam" coax. The cable has slightly better loss characteristics than the other RG-8 cables, but it is not meant for installations with continuous exposure to moisture.

A favorite coax for longer runs, up to 100 feet, is the Belden 9913 coax cable. Although it has a standard PVC jacket and cannot make tight turns, it does have lower loss at VHF and UHF frequencies than the RG-8 types. The 9913 coax has a 100 percent shield using a braid-covered foil. The inner insulation is semi-solid polyethylene and the center conductor is solid (size 10) bare copper. The air/polyethylene dielectric provides a velocity factor of 0.84. At 100 MHz it has 1.3 dB of loss per 100 feet, 2.7 dB at 400 MHz and 4.5 dB at 1 GHz. It can usually be purchased for less than $0.45 per foot in quantity.

Some recent variations of the Belden 9913 are also available, but at higher prices. The Wireman (phone 1-800-727-9473) sells Flexi-4L which has very similar loss characteristics to 9913, but uses a stranded center conductor for a better bending radius, and can be ordered with different jacket types for inside or outside use. The cost per foot is about $0.60. SSB Electronics (phone 1-717-868-5643) sells a popular European 9913-type cable called AIRCOM PLUS. The cable is very stiff due to the solid center conductor, costs $0.77 per foot in 328-foot rolls, but is advertised with loss characteristics that are even better than 9913 by a few tenths of a dB per 100 foot at most frequencies.

For the satellite frequencies in the HF spectrum (21 and 29 MHz) coax runs are not nearly as critical. For most applications, RG-8/U will be an excellent choice. The smaller-diameter RG-8/X (Belden P/N 9258) can also be used, although it has a standard PVC jacket and cellular polyethylene inner insulation. For short runs, RG-58A/U (inside) or RG-58C/U (outside) will do well. At 29 MHz, RG-58A/U has almost 3 dB of loss for 100 feet of cable, RG-8/X has about 2 dB, and RG-8/U has about 1 dB.

For satellite frequencies above 1 GHz, the cable can become a major financial problem. The 7/8-inch Heliax has an advertised attenuation of 1.31 dB per 100 feet at 1 GHz. This is still a 25 percent power loss, but it's much better than the 64 percent loss with 9913 or the incredible 99.3 percent loss with RG-58A/U. Lengths of RG-58A/U are sometimes used as intentional attenuators at UHF and SHF frequencies.

Connectors

As with cable, the primary rule with connectors is to stick with brand names. Most satellite hams have a good collection of Amphenol "UHF" and "N" connectors for their standard cable runs. A few other manufacturers of note include Kings and Trompeter. Avoid the no-name clones. Many look fine, but act as attenuators at higher frequencies due to tolerance problems and lossy dielectric material.

The so-called "UHF" connectors (SO-239 and PL-259) should be avoided above 148 MHz. Some purists have said that these connectors are great for CB and audio, but worthless elsewhere. Amphenol states that these general-purpose RF connectors are designed to operate

"satisfactorily" up to 300 MHz. If used properly, they will do fine for the satellite bands below 420 MHz, but even then, the Teflon™ insulation type should be used.

Above 420 MHz, "N" connectors are appropriate. They have a much higher voltage rating than UHF connectors and are typically rated for use up through 11 GHz. Due to a larger center conductor on 9913 coax, special "N" connectors are required. They usually have the same outer shell as those for RG-8 type coax, but have a special center pin to take the larger diameter center wire.

Some imported "N" connector clones have exhibited incredible losses at frequencies above 1 GHz. In high-power 1.2 GHz amplifiers, they may even get hot, assuming that other mismatch problems don't arise.

When installing connectors to coax, either follow the instructions that come with the connectors or check the *ARRL Handbook*. For outdoor connections seal the connector with non-corrosive RTV sealant and tape or thick-walled heat shrink tubing. The rig-to-antenna connection is the key to success for any satellite earth-station installation. 73

HAM TO HAM

Your Input Welcome Here

Dave Miller NZ9E
7462 Lawler Avenue
Niles IL 60714-3108

Spring is rapidly approaching—it would be nice to see more ideas and suggestions for spring and summer projects. What have you found that might benefit the rest of us? As always, any general ham-related ideas are welcome...here are a couple of my own.

A "customized" connector

I recently needed a 7-pin male DIN connector to plug into the accessory socket on my Kenwood TS-430S in a hurry — they're not the easiest of connectors to locate! So instead I bought an 8-pin DIN plug from Radio Shack™ (their #274-026) and was able to cut down the center 8th pin far enough (using a pair of small diagonal side-cutters) so that it fit nicely into the 7-pin socket on my transceiver. The spacing of the 7 remaining pins is the same as that of a true 7-pin DIN plug.

First aid for crumbling insulating tape

Some hand-held VHF/UHF transceivers come from the manufacturer with plastic tape laid across solder connections that might touch other conductive surfaces when the small circuit boards are finally "layered" together. After time, the tape and its adhesive dry out, literally turning to dust. I've found a suitable replacement tape, one that won't leave much residue when lifted up, as near as your local drug store.

The type that I've been most happy with is made by Johnson & Johnson; it's their 1/2-inch wide waterproof First Aid tape. It's a cloth based tape, with serrated edges, and has an effective, yet non-gumming adhesive backing. Of course it's intended to be used to secure a bandage, but it also makes a good general purpose insulating tape for use with low-voltage electronics. Since it's formulated to be waterproof, it doesn't seem too hydroscopic (prone to pick up moisture from the atmosphere), making it suitable for use in radios that will spend most of their lives in a mobile or marine environment.

Don't blow money on blown fuses!

From Herb Foster AD4UA: Here's an easy way to test a piece of equipment that continually blows the AC line fuse, without having to keep feeding it expensive little fuses.

Make up a trouble lamp with well-insulated clip leads on the ends of the AC cord, instead of the normal 2-prong AC plug. Install a 60 to 100 watt standard 120 volt lamp into the socket. Leave the fuse-holder in which the fuse keeps blowing empty, and clip the trouble lamp across it. When you apply power to the piece of equipment, the lamp will shine at near full brightness if the short in the circuit is close to zero ohms, or a bit less if it's not right at zero ohms, but still fairly brightly. Once you've cleared the short by lifting components or opening circuits, the trouble lamp across the fuse holder will glow very dimly when power is again applied, depending upon the amount of "normal" current that the device is actually drawing from the AC line.

Now you can disconnect the trouble lamp and reinstall a good fuse, knowing that the fuse will more than likely "hold" this time around.

Herb's suggestion works because a "cold" 120 volt lamp has very low resistance, and will therefore allow enough current into the troublesome circuitry if the short has been cleared, but not enough to cause harm if the short still exists, since its "hot resistance" is acting to limit the maximum current. A 60 watt, 120 volt bulb will be 15 to 16 ohms cold, a 100 watt 120 volt bulb about 9 or 10 ohms cold. It's a good way to dynamically test a piece of equipment without causing further harm. Just make sure that everything is well insulated—as Herb mentioned—and that you stay clear of the 120 volt circuitry any time the device is plugged in.

Pushing the (peak) envelope

From Ken Guge K9KPM: In the "old days," an amateur could determine his or her legal transmitter power by multiplying the anode voltage of the final amplifying stage times its current (the DC power input to the final transmitter stage), and as long as that figure was kept under the maximum allowable, that was all that the FCC expected the individual to know. It's not quite that easy today.

The FCC now expects an amateur to keep PEP (Peak Envelope Power) output under a certain maximum, depending upon the power restrictions of the license class and within the band that's being used. It's 1500 watts PEP for most operators on most of the bands, but that maximum is only 200 watts for everyone in Novice 80, 40 and 15 meter sub-bands and for Novice class licensees within the 10 meter band. Novices are permitted only 25 watts PEP on the 1-1/4 meter band and 5 watts PEP at 1270 MHz. All classes of licensees are restricted to 200 watts PEP throughout the 30 meter WARC band. It's 100 watts PEP for all beacon stations and 50 watts PEP within the 70 CM band in certain geographical regions. Refer to a current copy of the FCC rules for the specifics on any of these figures.

The point is that we can't just say "I'm running well under 1500 watts PEP so I'm safe." You're expected to know that you're within the legal limit, based upon your class of license and band of operation, and here's the way to do it.

PEP, or Peak Envelope Power, is the average RF power being fed into the antenna's transmission line (down at the shack), during one RF cycle, at the peak of the modulation envelope, with an SWR of 1:1 and under normal operating conditions. The most accurate way to measure PEP is with a monitor scope, coupled to your transmission line and terminated in the line's characteristic impedance (usually 50 ohms). The presentation on the scope face will be a peak voltage, so it's averaged by multiplying its value by .707. That answer is then squared and that result is divided by the 50 ohm transmission line impedance to get actual PEP power in watts. Sounds confusing, but here are some examples that might help clarify:

22 volts times .707 = 15.554 and 15.554 times 15.554 = 242 divided by 50 = 4.84 watts PEP

70 volts times .707 = 49.49 and 49.49 times 49.49 = 2,450 divided by 50 = 49 watts PEP

To calibrate your scope for 100 volts peak, put 100 watts into dummy load, with the scope in line, by adjusting the transceiver's CW key-down output while monitoring a wattmeter of known accuracy (some transceivers and dummy loads have an output wattmeter built right into them). 100 watts average into 50 ohms comes out to 100 volts peak (an interesting coincidence of numbers). Ohm's Law tells us that voltage is equal to the square root of the wattage times the resistance. 100 average watts of power times 50 ohms equals 5000, and the square root of 5000 is 70.7 (average voltage). 70.7 times 1.414 (1.414 is the multiplication factor that's always used to convert average to peak) = 100 volts peak voltage. Take a second to look it over again, don't get average and peak confused nor power and voltage mixed up. Also remember that "normal" wattmeters read average wattage, and the FCC wants us to know our PEP power output. Scopes will read peak voltage, and once the scope is calibrated correctly, you can use the examples above to determine the PEP wattage from the peak voltage that you've read on the scope.

Also notice that the relationship between peak voltage measured on the scope and PEP power is a logarithmic, rather than a linear, one. When the voltage doubles, the power increases by a factor of 4 to 1. When the voltage goes up by a factor of 10 to 1, the power increases by a factor of 100 to 1.

There are also peak-reading wattmeters commercially available to us as hams, but using a scope is the most accurate way of determining PEP power, and it's the only way to check the accuracy of a PEP meter. It's a good idea to be aware of (and practice) the scope method, just in case the legality of your PEP power output is ever questioned by the Commission.

Stealth chimney

From Bill Thim, Jr. N1QVQ: A different approach to a stealth chimney-mounted HF long wire antenna. Here's a suggestion for hams or SWLs living in a condo or other development that prohibits the installation of visible outdoor antennas of any type. Wanting to have a long-wire antenna that was totally invisible, and having a chimney made of brick and mortar, I started out at the bottom of the chimney, where a good ground is available, and laid #22 wire into the mortar joints between the bricks. I used a zigzag pattern as large as the chimney width permitted, then applied another "cover-up" layer of mortar on top of that. Upon reaching the chimney top, I dropped the wire through an unused flue pipe into the house. The average two-story chimney can accommodate 250 to 500 feet of wire — depending upon the width of the zigzags — by using this technique, and it's completely invisible except for a few inches at the base and a few inches at the very top. I was able to end up with nearly 500 feet of wire, which, via an antenna tuner, allowed me to copy all of the HF bands from 160 to 20 meters with surprisingly good results.

Bill also mentioned, that in his case, he had to get management's approval for the "tuck-pointing" work, but in areas where single family detached homes are the norm, that probably wouldn't even be needed. Bill hasn't used his stealth antenna for transmitting, but it should be usable on at least some of the HF bands, with the proper tuner in line and at reduced power levels. As he also pointed out, it's certainly better than no antenna! I wonder what the radiation pattern would look like on 20 meters?

Paint it silver

From Richard Measures AG6K: A cure for intermittent connectors in today's radios. The subminiature push-on, crimped-on coaxial connectors, used in many ham transceivers to interconnect RF or IF signals between circuit boards, can become intermittent or exhibit higher than near-zero ohms resistance on occasion. A poor connection at the center pin of these connectors can result in numerous intermittent output problems, in the case of a transmitter section, or varying sensitivity problems if the offending connector is in the receiver's circuitry. The crimp-on pins in these connectors have a tin plating, which, when crimped against the copper inner conductor of the subminiature coax, can create a dissimilar-metal electrolytic action that eventually turns the crimp connection into a semi-insulator.

Deftly soldering the tiny ends of these connectors, without damaging the coax cable inside, can be more difficult than some may want to risk, so another solution may apply if you're in that category. GC Electronics, among others, makes a conductive paint (Silver Print® is GC's brand name) that can be successfully used in these cases. It's normally sold through electronics component dealers, locally or via mail order. The silver conductive paint can be applied to the tip of the tiny coax connector with a straightened paper clip, coating the tip junction of the protruding wire and the connector pin surface to restore good contact.

The same scheme will also work for intermittent or high–resistance crimps on the small multi-pin control-cable connectors used in most modern rigs. The suspect female pin on one of these small connectors can usually be removed by carefully removing the connector, then depressing the tiny locking tab — accessible through the rectangular hole over each pin — with a scribe or small jeweler's screwdriver, and carefully slipping the pin back out of the connector body itself toward the wire's entrance. Don't pull too hard, or you may break the wire off completely. If the locking tab is depressed enough, you should be able to extricate the pin. Again, a dab of some conductive silver paint can be applied to the crimp connection with a straightened paper clip and allowed to dry before replacing the pin back in the connector. Don't forget to bend up the little locking tab again before reinserting the pin. You should hear or feel a tiny "click" as the tab engages.

Unless a crimped connection is so tight air is unable to reach the two conductive crimped surfaces, the electrolytic action that Rich speaks of is virtually inevitable, especially in areas of high humidity situations such as might be found in a mobile installation. There are well-applied crimped connections (partly dependent upon the design of the connector itself), but not every one can be assumed to be of that type.

Rich is a well-known author of numerous tips and equipment modification suggestions, perhaps most noted for his diligent work on HF amplifier parasitic suppression problems. Rich has delved into a number of modern transceivers and ferreted out the problem areas in those radios. Watch for other contributions from AG6K in the coming months. Thanks, Rich.

Keep the engine running!

From Peter Albright AA2AD: Another of his handy tips for quickly testing transistors in-circuit. The first "quick tip" that appeared in this column dealt with testing transistors statically and out-of-circuit, but it would be handy to do some preliminary testing without removing every transistor from the board! Here are some tips for locating defective transistors while they are still mounted on the board. The tests are run with the case opened and power applied, so please BE CAREFUL. In addition to the danger to yourself, troubleshooting a piece of equipment can be complicated by one slip of the test probe; you don't want to create additional circuit problems!

Good technicians always begin the troubleshooting process with careful observation. Is a transistor too hot to touch? Remember to keep one hand in your pocket when you stick the other into the equipment's guts, and keep both hands away from high-power RF circuits! Transistors can become quite warm, even in normal operation, but generally not hot enough to raise a blister. Conversely, if a transistor looks like it is designed to dissipate heat (a big case mounted on a hefty heat sink is a good clue), but it's cold to the touch even after several minutes of operation, it may not be conducting. Watch for those clues. Is there a resistor that's discolored from excessive heat? Has any component become so hot that the board is discolored? It may be normal, or it may be another clue.

After careful visual inspection, it's probably time to break out your trusty voltmeter. By the way, a digital voltmeter is generally better for these tests because of the often small relative differences involved. You'll see what I mean.

Transistors that are conducting normally show predictable voltage patterns. Specifically, the voltage drop between the emitter and base of a silicon transistor should be between 0.6 volts and 0.7 volts (about 0.3 volts for a germanium transistor). The voltage at the base should fall somewhere in between the voltage at the emitter and the voltage at the collector. For an NPN transistor, the collector will be more positive than the emitter. For a PNP transistor, the collector will be more negative than the emitter. While the voltage difference between the emitter and the base is 0.6 to 0.7 volts, the difference between the base and the collector is generally much greater. Remember that these values are relative to each other. Here's a chart of six imaginary transistors, showing logically possible voltages for each, relative to ground, that you're likely to find on a good transistor—one that's conducting normally. Note that these patterns do not apply to a good transistor acting as a switch in the "off" mode. Also, transistors acting as higher power RF amplifiers may check somewhat differently, but the chart does give you a good idea of the viability for the bulk

of the other transistors you're likely to find on a board.

NPN
e+2.0 e-2.0 e-.05
b+2.7 b-11.3 b+.02
c+12.0 c-3.8 c+48.0

PNP
e+12.0 e-3.8 e+48.0
b+11.3 b-4.5 b+47.3
c+2.0 c-12.0 c-0.5

Remember, the chart shows typical voltages measured with respect to ground, so don't expect them to be exact in any particular circuit that you might be troubleshooting. Again, what we're looking for here are indications of parameters that are grossly wrong.

Often it's easier to simply measure the voltages across the legs of the transistor, as opposed to measuring one junction to ground. If you can identify the emitter, and put one voltmeter probe on that lead, you will measure about 0.6 volts to the base with the other voltmeter lead; the meter will measure a greater differential to the collector. The polarity of the voltage will tell you whether the transistor is NPN or PNP; you can often identify the lead configuration of a good transistor by the voltage differences on these three junctions. Again, we're looking for relative differences across the device itself.

Although some physical lead configurations are more common than others, you can never assume that the lead configuration on two transistors is the same, just because they happen to look alike. The transistor manufacturers have done that just to keep us on our toes!

Peter offers some good practical advice in his treatment. As before, it's probably worthwhile cutting this information out and keeping it handy, for the next time you're faced with an involved troubleshooting job. A small plastic card file, with tips like these on the cards, will save you additional time and frustration trying to remember when and where you saw the information you need.

Scrub 'em, don't scrap 'em

From Klaus Wolter N8NXF: A method of soldering to aluminum without the need for special solder or equipment. Here's a technique that I've used several times with success:

1.) Carefully scrape the area to be soldered so that it's good and clean, and so that fresh, raw aluminum is exposed.

2.) Aluminum carries away heat very rapidly, so you must use an iron that's hot enough to keep a ball of solder molten once it's in direct contact with the aluminum.

3.) Firmly and consistently "scrub" the area on the aluminum to be soldered, then slowly apply regular 60/40 rosin core solder, trying to "rub it into" the aluminum with either a back-and-forth or a circular motion.

4.) If all goes well, you'll begin to notice that some of the solder ball is sticking to the aluminum; keep working the area until you've created the pad size that you want.

You should now be able to attach wires or component leads to this pad of solder. It's not easy, and it does require persistence and a bit of skill, but it can be done. Practicing on the inside of an empty aluminum beverage can will hone your skills in the procedure before trying it on a finished project.

Klaus' idea does work on certain types of aluminum; I've used it myself in the past. It may not work on all varieties of chassis material, since what we call "aluminum" can take on many variations in actual formulation percentages of other metals. I've also successfully used a soldering flux containing Zinc Fluoroborate, and Mono- and Di- Ethanolamine for soldering to some aluminums and stainless steels. One such product is manufactured by Henry Mfg., P.O. Box 155, Westville IL 61883. Long ago I heard that the "big secret" to soldering to aluminum is to not give the raw aluminum surface a chance to oxidize, which it does immediately upon contact with the air, and that seems to be why Klaus' technique works when used with the persistence he mentioned. Be cautioned that a copper-to-aluminum solder joint may not have the strength of a copper-to-copper solder joint, and its conductivity may alter over time. Good long-term conductivity in any solder joint requires that there be an alloy bond between the metals involved—this may not always be the case between tin/lead solder and some aluminum formulations.

At the end of your rope?

From Robert Blacka N2WSO: A tip that bears remembering when you're shopping for new rope for that upcoming spring antenna project. I was browsing through my local Home Depot™ home improvement center when I came across a variety of rope that yelled out "amateur radio!" Needless to say, I bought a couple packs! The product is called "Camouflage Poly Rope," and it's made by The Lehigh Group of Allentown PA.

It's reasonably priced, one quarter inch in diameter, rated at 113 pounds working load and virtually invisible against a background of trees or other vegetation. Perfect for ham antenna work! Side-by-side comparisons between the camouflage rope and standard white nylon antenna support line of an even smaller diameter confirmed the night-and-day difference in visibility. Even if the background isn't vegetation, the camouflage rope is tough to see in comparison with other solid-colored rope, because the human brain easily interprets straight lines of one color, but not of broken or random colors. The military discovered this decades ago and even Mother Nature herself has equipped many animals with a similar color scheme.

I've had several sections of Lehigh's "Camouflage" 1/4-inch rope out in the weather for over a year now, with no signs of deterioration. It appears to be conservatively rated by its manufacturer. It also appears to be a seasonal item, so ask about it if you don't see it stocked. It would probably find more widespread use among hams if it were available for sale at hamfests—now there's another idea for all of you weekend entrepreneurs!

And that concludes another month of Ham To Ham. Thanks to all who sent in their suggestions, tips, ideas and shortcuts...how about you? We've all discovered "better" ways of doing the average, everyday things we face in the pursuit of our hobby. How about sitting down for a few minutes, jotting down your ideas and sending them to the address at the masthead? I'll acknowledge all contributions and give you an idea as to if and when the tip will be used in the column. If it is used, Uncle Wayne's elves will send you ten bucks for your time and postage expenses. What a deal! I'll be back next month with many more worthwhile ideas.

NEVER SAY DIE

Continued from page 61

Weitbrecht W6NRM...but no one from Australia has ever bothered to let me know about what Syd was doing.

Come *on*, if a ham mover and shaker you know won't blow his own horn, it's up to you to pick up the slack. As Gilbert put it, "If you wish in the world to advance, your merits you're bound to enhance. You must stir it and stump it, and blow your own trumpet, or trust me you haven't a chance." Okay, what musical was that from?

The VK2SG obit mentioned that Syd, who died at 76, had been having health problems for the last six years of his life. To me that says that I need to do more to get the word out that health problems, almost without exception, stem from diet. If you put a little sugar in your car's gas tank every day you can easily cut your car's life in half. I'm not selling any fad diets or vitamins (yet, anyway), just asking you to read the books I've found that make the most sense when it comes to the maintenance of your body.

It makes sense to me to provide our bodies with the same raw materials our ancestors ate, drank, and breathed over the millions of years of our development. A Danish, coffee and Tang breakfast doesn't make any kind of sense. Nor does a burger, fries and milkshake lunch. Sure tastes good though. And drugs can make you feel good. For a while.

Another new technology

Secure Technologies Inc. of Lexington, MA, has come up with a neat little radio gadget. It's a range-finding unit which will help anyone keep track of where people or animals are. It requires a base unit and a small portable device which can be used to keep track of dogs, kids (at a mall, say), Alzheimer's patients, cattle or sheep herds, and even prisoners.

It uses a 900 MHz band transmitter n the base unit which sends out a 1 ms pulse of RF, modulated at 500 kHz. The portable unit receives this and retransmits it back on a different frequency (like a miniature repeater). The base unit measures the phase shift between the two signals and translates that into distance. The base signal also contains an identifying code so many of these units can be used in the same area without interfering with each other. If the distance exceeds an adjustable programmed number, the base unit will sound an alert.

This seems like a great way to cut the cost of prisons, with the authorities able to know whenever a prisoner goes beyond a given limit. It's a different and much lower-cost type of prison cell. With the base unit easily portable, it's easy to use it to find a person or animal that has gone beyond the limit set.

This is a clever use of electronics, but is it anything that you couldn't have developed, if you'd thought of it? If it is, then you haven't been learning your fundamentals, just memorizing your way to your ham ticket. Amateur radio is not only a way to have a whole lot of fun and adventures, it's also a license to learn and build your technical skills.

And for that matter, how come *you* didn't think of it? My excuse is laziness; what's yours? I'm too busy having a good time to sit down and think creative thoughts.

STI has come up with a great new product. That means they're probably going to be looking for investors to bring it to the market. They're going to need some hot sales people, advertising and promotion experts, and so on. They'll need engineers and technicians to help design, build, test, sell and service the stuff.

Cold fusion news

Big news! The US Patent Office has, for the first time, issued a patent on a device claiming to generate excess heat (2000%). Dr. Patterson had got a couple of patents on his cold fusion cells in which his supporting figures showed excess heat being generated, but he hadn't claimed that before. Now, in patent # 5,494,559, issued Feb. 27th, they've accepted his claim. Not

QRP

Number 62 on your Feedback card

Low Power Operation

Michael Bryce WB8VGE
2225 Mayflower NW
Massillon OH 44646

I admit I go through a lot more rolls of solder than logbooks. I enjoy the challenge of building new circuits. However, troubleshooting them can be an exercise in logic as well.

So it was when a friend of mine contacted me to take a look at the QRP transceiver he'd built, the QRP-15 CW transceiver by Rick Littlefield K1BQT.

Rick describes a small CW-only rig for the 15 meter band. This version, for 15 meters, is loosely based on his article, "An NE602 Based QRP Transceiver for 20 Meters." This article was published in *Ham Radio,* January 1989. Sorry, but I don't have access to either of the references mentioned. Check your local club's library for back issues.

In a nutshell, the rig is based on several NE602 mixer ICs. An analog VFO complete with an RIT circuit controls the frequency of the rig. The VFO operates from 5.000 MHz to 5.150 MHz. The RIT has a tuning range of about ±1.4 kHz. With the operating range set at 5 MHz, the IF dictated using a 16 MHz center frequency. While this may seem to be off the wall, in real life crystals for the filters and BFO are easy to obtain. They're commonly used in computers and other digital equipment. Both Digi-Key and Mouser electronics carry these crystals. They're cheap, too; about two bucks each.

Other than the 16 MHz IF, the rest of the rig is quite basic. However, in my friend's case, his version would not work.

First things first

Troubleshooting a home-brew project you put together yourself is one thing. Working on something someone clear across the country built is entirely different. So, the first step is to check for the usual cold solder joints and solder bridges. Finding none, we move up to the components and double-check for proper placement of all polarity-sensitive components, such as diodes and electrolytic capacitors. A quick check for the correct placement of all ICs is next in order. Also, and this may seems rather simple, but do check to see if each IC is in the proper location!

The simplest thing to do is take voltage checks of a kaput rig. A novice troubleshooter always asks, "Check what voltage where?" To begin, the best place to start is at the power supply jack, then work your way backwards. A 1N4002 diode installed backwards can keep the rig from working. Next, check for the proper voltage(s) at any of the three terminal voltage regulators. This includes their input and output pins. Take a quick look at the ground pin as well. The ground pin must read zero volts, not one or two volts. Unless the ground pin is held above ground by a resistor network, look for a cold solder joint or a cold solder joint someplace along the ground bus. In my case, the three terminal regulators were providing the necessary voltages.

Even if the required voltage(s) appears at the regulator(s), check each and every VCC pin on each and every IC. One cold or missing solder connection on the VCC pin will stop the rig dead in its tracks.

Here's a helpful timesaving tip for when you're checking for proper operation from a three terminal regulator. In the case of this 15 meter transceiver, there is one 7812 regulator supplying RIT circuit and the VFO/TX mixer. If you have your supply voltage (power supply, battery or whatever) set at 12 volts, the output of the 7812 will *not* be 12 volts. The three terminal regulators require several volts above their regulated output to operate correctly. If you like to operate by battery in the woods, then I would suggest replacing the 7812 regulators in all of your rigs with one of the low dropout units from National or Linear systems. Both companies make s :veral different voltage rating and current rating low dropout regulators. Some of these LVD regulators require only .3 volts above the regulator's output. For 12 volts at 1 amp, the LM2940T-12 is a perfect drop-in replacement for all of your TO-220 applications. For smaller current demands, the LM2950CZ-5 is available in the popular TO-92 case style. Both of these low dropout regulators are made by National Semiconductor.

The VFO—the heart of any rig

Now, I don't really care who said it, but finding the output of a VFO on a general coverage receiver is just plain nuts! You need a frequency counter. In this case, the VFO was running but at almost 8 MHz. The fix was taken in two parts.

First, the RIT coupling capacitor was removed from the VFO circuit. This eliminated any possible frequency shifting due to a messed-up RIT circuit. Fix the VFO first, then worry about the RIT.

Looking over the VFO parts, nothing seemed to be out of place. So, since the VFO was running too fast, making the output higher than needed, then one or more of the frequency-determining components was out in left field. Because the VFO *was* working, we knew the basic oscillator was running, so it was now just a matter of putting the output in its place!

Rick uses one NE602 as both the mixer and the VFO oscillator. It's a classic circuit and has been around since the NE602 first gained popularity. With plus 6 volts on the VCC pin, the output may be taken from either pin 4 or 5. With the RIT removed from the circuit, the only two parts that will determine the output frequency are coil L2 and the 50 pF variable capacitor.

To lower the frequency, we needed to add either capacitance or inductance. Had the VFO been running a tad too low, a simple and quick cheat would have been to remove one stator plate and check the output with the frequency counter. Removing stator plates is a whale of a lot easier than adding stator plates. However, we could add an external capacitor to pad down the tuning capacitor, leaving both stator and rotator plates untouched. While in theory this does work, it also reduces the amount of tuning range we could get. This is exactly what the calibration trimmer does to the circuit. It adds oh-so-slight an amount of capacitance across the tuned circuit, lowering the oscillator. In the case of our 15 meter rig, the calibration capacitor was rated at 8 pF.

The only sure-fire fix was to remove L2 and rewind it. Sure enough, there was not enough wire on the toroid; this easily increased the frequency of the VFO. To make matters even more interesting, the difference of one or two turns really shot the frequency up or down. After I had the windings in the right neighborhood, I applied some SuperGlue gel to hold the turns in place. That fixed the VFO and it operated in the frequency range it was designed for.

The output of the VFO goes to the TX mixer, another NE602. Between the VFO and the TX mixer, Rick uses an MPF102 to buffer the VFO's output. From the drain of the MPF102, RF is picked off via a 500 ohm trimmer. Although the trimmer is not critical to set, use caution so you do not apply too much RF to the mixer. All kinds of nasty things will crawl out of the NE602 if you overdrive this mixer.

The best way to set the TX mixer level is to monitor pin 1 of U6 with an oscilloscope. Adjust the mixer drive until the signal begins to flatten off. Now reduce the drive just a bit, so all you see is a clean sine wave going into the TX mixer.

Transmitter

Since this is the easiest part of the rig, let's follow the output from the TX mixer to the antenna.

By using your Tscope, you should see the input from the VFO on pin 1 of U6. IC U6 mixes the VFO signal with the signal provided by Y1. Again, as in the VFO, Rick used the NE602 as an oscillator. Check for operation of Y1 at pin 6 and 7 of U6. (I'm not able to reproduce the actual schematics.)

Output of the mixer, now at the frequency we want (in this case 21 MHz), should appear at the base of the driver transistor, a 2N5109. If not, then there's a solder bridge between pins 4 and 5, or L7 is wound incorrectly. Adjusting the TX/MX trimmer should produce a peak at the base of the driver.

Move forward to the final. RF, now rather heavy, should be on the base of the MRF475. Check for +12 volts on the collector of this transistor. If you read zero volts DC, then there is a wiring error in T1. If everything is working as it should, you'll see about 2 watts output to the antenna. *If everything is working.* And that's where we'll pick it up next month as we fix and improve the 15 meter transceiver. 73

Adjusting the epithet

We hams are famous for acronyms and abbreviations. Whether it's RTTY, AMTOR, QSL, or plain old CW, every letter has a meaning, no matter how obscure. In my warped mind, MFJ always stood for Mighty Fine Junk; after this month's batch of offerings from them, I may have to change that appellation.

Many readers will remember my tale of the bow and arrow placement of my antenna some years back. The version of the G5RV antenna I put up cost me about $50, and now, several years later, it has broken at the balun. Just the ticket to replace it is MFJ's version of this venerable antenna. This efficient 102-foot doublet runs all bands in the 80 through 10 meter range, with 160 as an option with a tuner and ground.

Fully assembled, the antenna features strain relief feed points, custom-made Fiberglas™ insulators, and heavy gauge wire that's capable of running the legal limit. All this, for a nickel under $30. **Photo A** shows you the whole picture. Wouldn't you like to have one in your backyard? I don't know about you, but as soon as our weather here in the East breaks — it's been winter for about three years, I think — I would love to have one of these to replace the aging skyhook out there now.

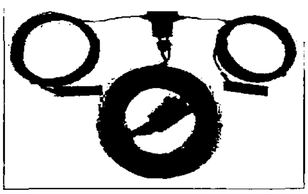

Photo A. All this, for a nickel under $30.

The little box in **Photo B** is the MFJ Multi-Reader, MFJ-462B, a $170 device that decodes a plethora of digital modes. Capable of decoding Morse, RTTY, and ASCII, this self-contained demodulator can either display incoming traffic on its built-in LCD display, or output them to a printer via an integral printer port. If you're into SWL or monitoring, this would be a simple way to go, to get dedicated digital reception at a reasonable price.

"If you're into SWL or monitoring, this is the way to get dedicated reception at a reasonable price."

On the other hand, if full-scale digital communication is more your style, have a look at the MFJ-1278B, their DSP multimode controller that does just about everything. With the sleek case, shown in **Photo C**, and with digital modes including RTTY, CW, packet, PACTOR, AMTOR, color SSTV, and gray level FAX, about the only thing this box doesn't do is fill in the logbook. There's a built-in 32k mailbox, expandable to 512k, a built-in parallel printer port, and, unlike another unit I've seen, this one comes with its own 110 volt power supply.

The c ontroller is available in several flavors, for several budgets, ranging from the basic MFJ-1278B for $300, without DSP, all the way up to the MFJ-1278B/DSP, featuring the "brick wall" DSP filters, for $380. MFJ's own software package, the MFJ-1289, is designed to take full advantage of the features of these controllers, and is sold separately. Again, here is another honey I'd love to replace an older unit with. Is anyone at my house reading my column?

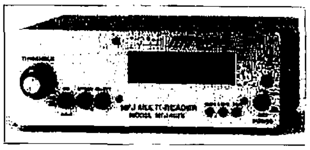

Photo B. The MFJ Multi-Reader, a little box that decodes a plethora of digital modes.

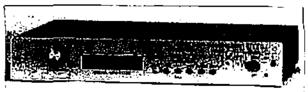

Photo C. About all the MFJ-1278B doesn't do is fill in the logbook.

Information on all of these products may be obtained from MFJ, at P.O. Box 494, Mississippi State, MS 39762, or call them at (601) 323-5869. Just be sure to tell them you read about it here, in RTTY Loop.

A few months ago, I mentioned the Snappy video digitizer, and invited those of you using the device to submit pictures of you or your projects. I received an E-mail from Bob KI5PG, who says he is a regular reader of the column. He purchased the Snappy video capture device, and is really having fun with it. Right now, he is using it to prepare illustrations for a short article on wiring the communications headsets sold for $5. I wonder if he will send the article to *73?* Anyway, **Photo D** is a picture of Bob, sent via the Internet.

Here are some interesting WWW links this month, passed along by Dave Horsfall, VK2KFU, in Sydney, Australia. He suggests: http://www.nsw.wicen.org.au/ the home page of the Wireless Institute Civil Emergency Network, in New South Wales. Sort of like the ARES/RACES, it contains information of interest to WICEN members and other emergency-related people, and has links to related sites.

Another of his hot hits is: http://sydney.dialix.oz.au/~wiansw/ the home page of the NSW Division of the Wireless Institute of Australia (WIA), their national amateur radio organization. You'll find information about the WIA, and links to other pages as well.

Of course, the RTTY Loop Home Page, at: http://www2.ari.net/ajr/rtty/ remains quite active, with many of you stopping by daily. Check there for recent columns, the full list of software in the various RTTY Loop collections, links, and other goodies. I look forward to hearing from you by E-mail at ajr@ari.net, or on America Online at MarcWA3AJR, or on CompuServe at 75036.2501. Non-line amateurs, feel free to drop me a letter at the address up top. Questions, comments, suggestions or critiques are always welcome, but be sure to include a self-addressed, stamped envelope if you desire a personal reply by snailmail.

Next month, even more as we conclude the nineteenth year of RTTY Loop! 73

Photo D. Bob KI5PG, via the Internet with Snappy.

Ham Radio Fun

Communications Simplified, Part 5

by Peter A. Stark K2OAW
PO Box 209
Mt. Kisco NY 10549

Having looked at the types of signals we may want to communicate, let's look at some methods for sending them through wires and fiber optic cables. Some of the methods we will describe depend on ideas and concepts which we will not cover until later; hence this discussion will be fairly low-level. We will fill in some more details later, as we learn more about the theory. (Continued from April 1996.)

Normal telephone circuits

Normal telephone service (often affectionately called *POTS* or *Plain Old Telephone Service*) uses 600-ohm balanced line and carries analog signals (as opposed to the newer digital lines, discussed later.) The cable carries audio in both directions at the same time, and this is called *full duplex* (as opposed to *simplex,* where a signal goes only one way, or *half duplex,* where a signal can go in both directions, but in only one direction at any given time.) Since audio goes both ways and distances tend to be long, the cable must be terminated in its characteristic impedance at both ends. Thus your telephone set is designed to have a 600-ohm impedance, and so is the circuitry in the phone company's central office.

Telephone lines come in two different types—*switched* and *dedicated* or *leased*. Your normal household telephone connects to a switched line, meaning that it connects to the phone company's switching circuits, which allow you to dial a number and be connected, through the switching circuits, to any other subscriber's telephone (*subscriber* is simply another word for customer). This dialing network (or switching network) is also sometimes called the *DDD* or *Direct Distance Dialing* network.

A leased line, on the other hand, bypasses the switching circuits and is directly and permanently connected between two subscribers. Rather than pay for such a line by the call, you pay by the month.

Since switched lines go through a lot of equipment, they generally have a limited frequency response, and substantial noise and distortion.

Moreover, each time you place a call, your connection is likely to go through a different route, so the noise and other distortions are different with each call.

Leased lines, on the other hand, always go through the same wiring, so their characteristics stay the same. They also bypass much of the circuitry that distorts signals or adds noise. Not only is signal quality better to begin with, but that also means that either the telephone company, or the user, can add additional equalizers and other circuits to improve the line even more. Such lines cost more, but can be used in places where a plain line cannot. For example, radio stations often rent such equalized lines (called *conditioned* lines) to carry high quality audio from their studios to their transmitters.

The above description holds quite well for short-distance connections (such as within a small town), but the picture changes when longer distances have to be covered and the signal gets too weak to make it without amplification. It is possible to insert a bi-directional amplifier into a full duplex line (meaning that the amplifier can amplify two signals traveling in opposite directions on the same line at the same time), but this introduces some other problems. For long-distance transmission, the telephone company therefore splits the full-duplex single line (usually two wires) into two simplex (one-directional) circuits; since this involves a total of four wires, it is called a *four-wire circuit.* This conversion is done with a device called a *hybrid* or *duplexer*. Once split into a four-wire circuit, the two simplex signals can be sent via wire, microwave radio, optical fiber, satellite, or virtually any other one-way medium.

The two-wire line which enters your home or business is generally called the *local loop*, while the four-wire line which carries the call between telephone company equipment (and other lines as well, which might be used not just for your conversation, but for others as well) is called a *trunk*.

Digital telephone lines

As of right now (1996), the telephone line—the local loop—entering your house is purely analog, meaning that the signal traveling in it is a wave shape which closely matches the wave shape of the sound of your voice. Many telephone lines, however, are purely digital.

Since even a moderately long telephone connection uses a four-wire trunk line at some point, carrying a separate set of four wires for every telephone call between large cities could obviously get very expensive. The telephone companies therefore send many different calls through a single cable at the same time, using a process called *multiplexing*.

Early multiplexing techniques were analog; the multiplexer at the sending end would change each signal into a different frequency range, and the modified

signals were then all sent through the same cable. At the receiving end, a *demultiplexer* would separate the signals, and change them back to the original frequency ranges. This concept was called *frequency division multiplexing* or FDM.

But FDM is an analog approach which is subject to noise and distortion. In an effort to reduce these effects, especially when a signal is sent through some combination of cables, microwave links, and other paths over a long distance. FDM has now been replaced by a digital approach. Right now, the actual local loop going from your home to the telephone company's central office is still an analog 600-ohm line. In the central office switching circuits, however, that signal is then converted to a digital signal by a *codec*, which is a coder–decoder circuit which converts to and from digital. The signal stays digital all through the network, until it is converted back to analog by another codec in some distant central office and sent to the person you are speaking with through his local loop.

In long distance circuits, the basic digital connection is called a *T3 digital carrier system*, which transmits digital data at a rate of 47.736M bps (47.736 million bits per second.) The T3 line can then be split into seven T2 lines, which operate at 6.312M bps; these in turn can be split into four T1 lines, which operate at 1.544M bps. Each of these can in turn be split into 24 digitized voice channels. (You will note that these numbers don't exactly multiply out to the correct values; that is because each of these T lines also carries some signaling bits.) A T1 line can therefore carry 24 voice channels at the same time, a T2 line can carry 96, and a T3 line can carry 672 voice channels.

The change to a digital network was actually driven by another problem. In order to tell the circuits at the far end of a connection how to route a call, the telephone companies needed to send additional signals through long-distance circuits. The original approach was to send these signals as audio tones (similar to the Touch-Tone tones we now use for dialing, but at different frequencies) right through the same circuits as the phone calls themselves. But some time in the 1960s or 1970s, telephone hackers called *phone phreaks* learned how to fake these tones, using a device called a *blue box*, to make free phone calls. The only way to eliminate this practice, as well as provide new services such as Caller ID, was to provide a completely different data path for the signaling signals, separate from the audio path, so there would be no way for a hacker to inject fake signals into the network. This has resulted in a complete redesign of the long distance network, making almost all the trunk lines, both those for digitized audio as well as those for signaling, completely digital.

If you have a lot of digital data to send, you can lease a T1 line, or a part of a T1 line (called *fractional T1*). Right now, this is a fairly expensive proposition which requires special wiring, so it is used only by larger businesses.

To lower the cost, a new system called ISDN or the *Integrated Services Digital Network* is being installed in larger US cities, as well as in many countries overseas. The idea is to bring a digital connection directly to your home or small business through the same twisted pair (refer to April's *Communications Simplified*) now used by the local loop connections, and put the codec directly into your telephone. This not only improves the quality of the connection — since it eliminates the last analog lines which might pick up noise — but also makes it possible to use the same lines for high speed digital non-voice applications.

The "Basic ISDN" connection, suitable for a home or very small business, is a single local loop twisted pair line which carries data at 144K bits per second. This is split into three channels, two at 64K bits per second and one at 16K bits per second. The 16K bps channel can be used for signaling or data, while each of the two 64K bps lines can carry a voice channel, FAX, or even high speed computer data.

A higher-speed ISDN connection, called "Primary ISDN," is available for larger businesses; it operates at 1.544M bps (like a T1 line), and can be split into 24 digital channels.

Although ISDN is here and now, it is only gradually being introduced. For example, even in New York City it is only available in some relatively small areas. But that will probably change in the future, especially since the local loop wiring is a big part of the telephone company's investment. Since ISDN basically doubles the number of voice channels that can be used on each local loop, there are great advantages in using it.

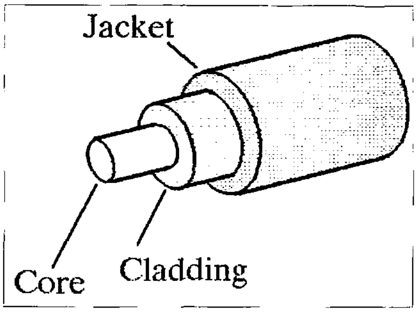

Fig. 1. Construction of an optical fiber cable.

Before going on, we shouldn't forget the other company that is in a position to offer you telephone service — your local cable TV company. Since so many homes are already wired with high-quality coax cable for cable TV, the cable companies are actively working on using those same cables for telephone service. One of the major hangups has been how to interconnect the cable companies' telephone subscribers with those of the traditional telephone companies, but in early 1995 there were several agreements between cable and telephone companies on how to do that. The major point of agreement was to allow subscribers to change companies without having to change their telephone numbers as well. This problem has been resolved, and so it's quite likely that "cable telephone" service will be around soon, especially since Congress has recently passed the 1996 Communications Act, which permits all sorts of new competition.

Radio-frequency signals

Just like audio signals can be sent through either shielded unbalanced cable, or through balanced cabie, so can radio-frequency (RF) signals. But at the high frequencies used for radio signals, most cables wind up being quite long compared with a wavelength, and so it is important to pay attention to the impedance of cable, load, and source, to avoid reflections.

Relatively little balanced cable is used for RF. The most common one is the thin "twin-lead" cable used for TV antennas, which has a characteristic impedance of 300 ohms. Because balanced cable can have a lower loss than coax cable in some applications, balanced cable is also sometimes used in other places, but not

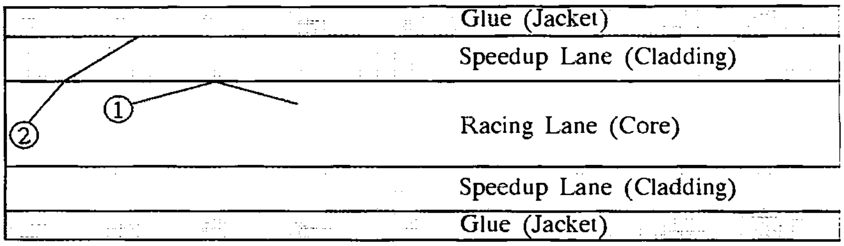

***Fig. 2.** The cladding steers light back into the core.*

as often. Most coax cable is 50-ohm or 52-ohm cable (the difference is unimportant). Some 75-ohm cable is used, but mostly in TV antennas and cable TV installations. The reason TV uses 75-ohm cable rather than 50-ohm cable is that 75 ohms is exactly one quarter of 300, which makes it slightly easier to convert back and forth between the two types of TV antenna cable.

At extremely high frequencies, the insulators used for balanced or coax cables have too much loss, and so a special kind of "rigid cable" is used which has no insulator at all, other than air. It is called waveguide, and is actually more a pipe than a cable.

Keep in mind that high-speed digital signals behave somewhat like high-frequency radio signals. Hence all the cautions about watching the characteristic impedance of lines, and properly terminating them, are also important for digital applications. For example, the coax lines used for LANs (local area networks used with computers) also need to be properly terminated. Many LANs use coax lines (both 50-ohm and 93-ohm), although unshielded twisted pair (UTP) lines are also popular.

Optical fibers

As fiber optic cables fall in price, they are being used more and more for communications. In a nutshell, electrical signals are converted into a light beam (possibly visible, but more likely infrared) with an LED (light-emitting diode) or laser, the light beam is sent through a fiber made of glass or plastic, and then converted back into an electrical signal with a photodiode or phototransistor. Thus the fiber cable simply replaces the copper wire.

A major difference, however, is that optical fiber communications are almost always digital. The reason is that it is easy to switch a light beam on and off, even at high speed, to carry digital data. But to carry analog data directly would require that the brightness of the light be varied in step with the analog data: this is difficult to do with any degree of precision.

Fiber optic cables can be made of either glass or plastic. A typical cable generally looks like **Fig. 1**, and consists of three parts:

a. The *core* is at the center. Made of very pure and clear glass or plastic, the core passes the light beam from one end of the fiber to the other.

b. The *cladding* is a second layer of glass or plastic, wrapped around the core. This layer is made of a slightly different glass or plastic, one that lets light travel just a bit faster than the core.

c. The *jacket* covers the outside of the fiber and protects it.

To understand how this works, imagine that we are laying out a race course for blind runners. Since the runners can't see, how can we keep them from wandering outside their lanes? One way, of course, would be to put a picket fence at both edges of the lane, but that's not very humanitarian — every time a runner hits the fence he will get all scratched up or bloodied, and pretty soon he will give up.

So we come up with the brainstorm of **Fig. 2**. First we lay out the actual lane, labeled the racing lane in **Fig. 2**. On each side of the racing lane we put a second lane made of a slightly different material, one which gives the runners slightly better traction so they can run just a bit faster on it. This is labeled the speedup lane in the figure. Finally, at the very edge, just in case a runner gets too far off course, we'll put a layer of glue to stop him so he can't wander back into the course and get in someone else's way.

So now look at runner 1, who's running at a slight angle to the course. As soon as he enters the speedup lane, his left foot will have slightly better traction than his right foot, so his left side will wind up traveling just a bit faster. This is going to turn him slightly to the right, so he goes back into the racing lane. Runner 2, on the other hand, is so far off course that he too will turn a bit to his right, but not enough to return to the course. He will eventually get stuck in the glue, and that will keep him out of trouble.

So the whole idea is that the speedup lane keeps the runners from straying off course, without in any way hurting them or slowing them down. The optical fiber works exactly the same way. The cladding is made from a glass that lets light travel just a bit faster than the core. When a ray of light tries to leave the core and enter the cladding, it gets bent back just enough to re-enter the core. If it's like runner 1, it returns to the core and keeps going. But if it's like runner 2, then it goes right through the cladding until it hits the jacket, and gets stopped.

Although the best cables are all glass, they are also available in pure plastic, or in plastic-clad silica (PCS) cables which have a plastic cladding and a glass (silica) core. The glass cables perform much better, but also cost much more. The following table lists some of the characteristics of a few different kinds of fiber cables:

Type	Attenuation (dB/km)	Bandwidth (MHz-km)
Glass	0.5	1000+
PCS	10	20
Plastic	400	20

Table 1.

Let's look first at the attenuation of these three sample cables, and compare them with copper cables.

The attenuation of various copper cables increases with the frequency of the signal. For example, good quality RG-8 with a foam dielectric has about 1.2 dB loss per 100 feet at 50 MHz, about 2 dB loss at 150 MHz, and 3 dB loss at about 300 MHz. Let's look only at the loss at 50 MHz, since that is close to the 47.736 MHz data rate of a T3 line.

Since there are about 3300 feet in a kilometer, a 1 km length of RG-8 would have about 40 dB loss at 50 MHz. Even one of the best and most expensive coax cables (7/8-inch diameter hard-line) would have a loss of 12 dB per km at 50 MHz. Compare this with the 0.5 dB per kilometer loss of a good glass optical fiber.

The attenuation determines how long a cable can be used before the signal becomes too small to be useful. Because of their low loss, the maximum usable length of a plastic fiber is a few hundred feet — long enough to go within a building, but not much more. PCS fiber cables, and coax wires, can be used for a few km, while high quality glass fibers can go 30 km or more. In a long distance circuit, such as the telephone company might use between cities, repeaters must be placed at intervals to amplify and reconstruct the digital signal. When a glass fiber is used, these can be much farther apart than when a copper cable is used — sometimes as much as 20 to 30 miles apart.

Another aspect, of course, is the bandwidth. The bandwidth of an optical fiber is rated in "MHz-km." For example, for a plastic fiber, this number is 20 MHz, meaning that a 1 km length (about 3300 feet) has a bandwidth of 20 MHz, a 0.5 km length has a bandwidth of 40 MHz, while a 10 km length would have a bandwidth of just 1 MHz. This makes it look as though plastic cable doesn't have nearly enough bandwidth for any real digital data transmission. But because plastic cables are only used in short lengths, their bandwidth is adequate.

But look at the bandwidth of the glass fiber, shown as more than 1000 MHz-km. Even in long lengths, glass fiber has a large bandwidth. It can carry many more voice conversations, for example, than a copper cable. There are systems that can carry as many as 30,720 telephone conversations in one cable, a feat which cannot be done with copper cables.

As a result, even though glass fibers cost much more than even good quality coax cable, their higher bandwidth, and the ability to go longer distances between repeaters, outweighs their higher price and makes them attractive.

Decibels

We have used decibels (abbreviated dB or sometimes dB) in the previous section, without really explaining them. Decibels or dB are important enough that a mere detour to cover them is not enough, so here is a more complete explanation.

The decibel originated in the telephone industry. The prefix *deci* means a tenth, so a decibel is really a tenth of a Bel, a unit named in honor of Alexander Graham Bell, the inventor of the telephone. But the Bel is too big a unit for most uses, so everyone uses decibels instead.

The decibel is usually used to compare an "after" with a "before." For example, we might compare the power after an amplifier (coming out of it) with the power before it (the power going into it.) The formula is then dB = 10 $\log_{10}$ Power after/ Power before (the factor of 10 converts the Bels into decibels.) The ratio of Power after/Power before is often called a *power gain ratio* or just plain gain ratio.

For example, if an amplifier takes a 1-watt signal and amplifies it to 100 watts, the gain would be dB = 10 $\log_{10}$ 100/1 dB = 10 $\log_{10}$ 100 and since the $\log_{10}$ of 100 is 2, the answer is 10 x 2, or 20 dB.

You've probably forgotten that $\log_{10}$ means the "logarithm base 10." This is the "power to which you'd have to raise 10" to equal 100. In this case, $100 = 10 \times 10 = 10^2$, so to make 100, you have to raise 10 to the second power. Hence the logarithm of 100 is 2.

If you have a modern scientific calculator, calculating logarithms is a lot easier than when I was in school. Still, we can save ourselves a lot of work if we make up a table like this:

Power Gain Ratio	db
100,000	+50
10,000	+40
1000	+30

0.001	-30
0.0001	-40
0.00001	-50

Table 2.

The important thing to notice is that when the power gain ratio is larger than 1—which means that the power after is larger than the power before—the number of decibels is positive. On the other hand, if the power gain ratio is smaller than 1—which means that the power after is smaller than before—the number of dB is negative. Therefore a positive number of dB means a gain, whereas a negative number of dB is a loss. (By the way, -3 dB represents a power gain ratio of 0.5, and so many people refer to -3 dB as "half power.")

For example, we said earlier that a 1 km length of foam RG-8 cable would have about 40 dB loss at 50 MHz. That translates to -40 dB (negative because it is a loss), so the power gain ratio is 0.0001. That means that the power after the cable is only 0.0001 times as large as the power going in. If you sent 1 watt into the cable, only 0.0001 watt would come out after just one kilometer, or about 3300 feet.

Compare that with glass fiber, which has a loss of 0.5 dB (which is really -0.5 dB) per kilometer. In six kilometers (about 4 miles), this adds up to -3 dB, and the above table tells us that is a gain ratio of 0.5. This means that the power coming out of a 4-mile length of glass fiber is half of what went in. This is an astounding number—just visualize how clear a piece of window glass would have to be if it were 4 miles thick, yet half of the light going in would still come out the other end!

Besides comparing powers, decibels can also be used to compare voltages. But in this case the equation has a 20 instead of a 10 in front of the log, and it becomes dB = 20 $\log_{10}$ Voltage after/ Voltage before.

This makes all the dB values twice as large, and gives us the following table:

Voltage Gain Ratio	db
100,000	+100
10,000	+80
1,000	+60
100	+40
10	+20
2	+6
1	0
0.5	-6
0.1	-20
0.01	-40
0.001	-60
0.0001	-80
0.00001	-100

Table 3.

For example, if an amplifier takes 1 volt in and produces 10 volts out, the voltage gain ratio would be 10, and so the gain would be +20 dB. As before, positive values are a gain, while negative values mean there is a loss.

My students often ask why we use decibels at all, when we could leave gains expressed as ratios instead. The main reason is that it makes calculations a lot easier when a signal goes through a chain of circuits, one after another.

For example, suppose a signal goes through an amplifier with a power gain of 100 (+20 dB), then through a volume control which drops the voltage in half (-6 dB), and another amplifier with a power gain of 10 (+10 dB). Figuring out the gain of the entire chain is easy with decibels — we simply add +20 -6 + 10 = 24 dB. If we try to do it with gain ratios, we get all bollixed up because the amplifier gains are given as power gains, but the volume control is described in terms of voltage.

If you have the patience to see how this would work, here goes: since the formula for power is $P = V^2/R$ the power is proportional to the square of the voltage. Cutting the voltage in half (in the volume control) therefore cuts the power in a quarter. The power gain ratios would then be multiplied as 100 times 1/4 times 10, which gives 250. When we plug this into the dB formula, we get $dB = 10 \log_{10} 250/1 = 10 \log_{10} 250 = 10 \times 2.4 = 24$ dB.

How do we convert from dB back to a plain ratio? This isn't done nearly as often as converting to dB, but it still is useful to know. Let's do it for the 24 dB answer. First, assume R stands for the gain ratio, so we have: $24 = 10 \log_{10} R$.

Next, divide both sides by 10: $2.4 = \log_{10} R$.

We now remember that the log of a number is the power to which we must raise 10 to equal the number. So 2.4 is the power that we have to raise 10 to equal R. That is, $10^{2.4} = R$.

We really need at least a calculator to get this answer; the best we can do without the calculator (or at least a book of tables) is to try to approximate. Since $10^2 = 100$ while $10^3 = 1000$, at least we can estimate that $10^{2.4}$ must be somewhere between 100 and 1000, probably closer to 100 than to 1000.

Conclusion

Communications over wires is the oldest form of electric or electronic communications, but it is still in wide use all over the world. And it's not likely to ever be replaced, even though optical fibers are making great inroads.

In fact, with today's ever-increasing need for more and more communications, wires and fibers are becoming more important than ever. While it would be nice to use "wireless" methods like radio, there are severe limits to the amount of information that can be sent in this way; there is just not enough space for everyone that wants to use it.

One of the biggest users of scarce radio space is TV. Some years ago, several TV channels were taken away from TV and reassigned to other uses (such as cellular phones); with the expansion of cable TV and satellite TV, this may even happen again.

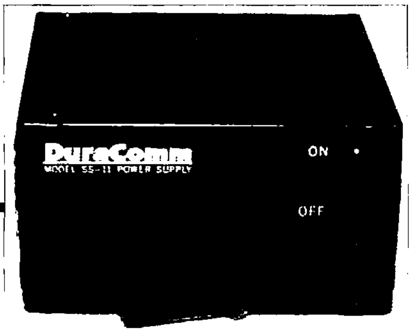
73 Review

The Ten-Tec SS-11 Switching Power Supply

Neat, compact, lightweight.



Joseph M. Plesich W8DYF
173 Brockton Road
Steubenville OH 43952

What I needed was an AC supply capable of powering my Ten-Tec Argosy II. It's a great little transceiver that runs 50 watts on CW and SSB, so I needed something more practical than the 11-pound monster I had on hand.

While reading the advertisement for the Ten-Tec Scout (which I hope some day to own), I noticed that one of the supplies available for it is a little three-pound 11- amp supply. If it would power the Scout, it would certainly power my Argosy. I ordered it.

The SS-11 supply converts 120 or 240-volt 50/60 Hz AC to low noise and ripple regulated 13.8V DC. The operating voltage is selected by a switch on the rear panel. The power supply is protected against inadvertent shorts and overloads by an electronic output current limiter. This circuit reduces the output current to a very low and safe value until the overload is removed, when the output is automatically restored after the unit has been turned off for 15 seconds. It also has an over-temperature protection feature. The unit will provide 12 amps surge and 11 amps continuous duty and it measures only about 3"H x 6"W x" 5-1/2"D.

I've been using the SS-11 to power my Argosy and it doesn't even get warm. You could also use it to power a tape player, an FM or a QRP rig. It's a neat, compact, lightweight supply that's real handy around the shack. For $95, in my opinion, it's a very good buy from Ten-Tec: 1185 Dolly Parton Parkway, Sevierville TN 37862 or 1-800-833-7373.

Homing In

Homing In Radio Direction Finding

Joe Moell P.E. KØOV
PO Box 2508
Fullerton, CA 92633

More foxhunts coming up — let's build a yagi!

Hardly a week goes by without hams telling me how much fun they had at Hamcon/Foxhunt-95. This international-style radio direction finding (RDF) contest, part of the ARRL Southwestern Division convention last Labor Day weekend, was one of the first such events ever staged in the USA. Despite the fact that Southern California is the transmitter hunting capital of the USA, a formal all-on-foot hunt under International Amateur Radio Union (IARU) rules had never been tried here before.

Perhaps you read about international-rules foxhunting and Hamcon/Foxhunt-95 in "Homing In" for December 1995 and January 1996. Many readers wrote or E-mailed to declare their interest in holding similar events in their localities. If the trend continues, it may soon be possible to establish an official foxhunting committee for IARU Region 2 (North and South America). Such a committee is necessary to sanction local foxhunts as qualifying rounds for future world championships.

If reading about Hamcon/Foxhunt-95 has made you eager to try this type of radiosport for yourself, plan now to attend the 1996 West Coast VHF/UHF Conference, May 3 through 5, near Los Angeles. In addition to the usual displays and technical sessions on propagation, mountaintopping, and contesting, this year's conference features both a traditional Southern California mobile T-hunt and an IARU-style foxhunt.

Both hunts are being sponsored by the Southern California Six Meter Club, the same group that put on Hamcon/Foxhunt-95. Transmitters will be on 2 meter FM. The foxhunt will begin Sunday afternoon at a site not far from the convention center. Don't forget your RDF gear!

Gather your sporting goods

I lost count of the would-be foxhunters who stopped by the sign-up table at Hamcon-95 to say they wished they could go on the hunt, but didn't have any suitable equipment. Actually, it's easy to get set for this type of RDF contest. You could build or buy a dual-switched-antenna "homing" device, as some competitors did. A few entrants brought special foxhunting beam-receiver sets made in Japan or Russia. But the majority of runners used the tried and true amplitude-based RDF method: just a directional antenna, RF attenuator, and handie-talkie with S-meter. Some carried full-sized three-element yagis, while others held wire quads, similar to the ones they like for mobile T-hunting.

The most intriguing antenna I saw at Hamcon/Foxhunt-95 was carried by Glen Allen KE6HPZ of the Downey Amateur Radio Club (**Photo A**). Its two closely spaced aluminum elements were about the same length. It looked like a phased array, but I couldn't be sure because its feed system was concealed in PVC pipe. Glen said it was a yagi. I figured that such close spacing would not give him much sensitivity, since high gain is normally associated with long boom antennas. Thus, I was truly impressed when KE6HPZ won first place in the Masters age division. In fact, he was the only one in his division to find all six foxes within the allotted time.

Photo A. Glen Allen KE6HPZ (second from left) had one of the smallest 2 meter RDF antennas at Hamcon/Foxhunt-95, but that didn't keep him from taking first place in his division.

KE6HPZ's yagi was designed by Doug Lyon N6WZI, a fellow Downey club member (**Photo B**). Doug told me that this antenna, which he calls the RDF², came about after he tried a number of multi-element yagis and quads and found them to be "too big and clumsy," to use his words. He set out to design his own model, one that would be light but sturdy, easy to build, compact and inexpensive. It had to have enough gain to hear distant milliwatt foxes and sufficient front-to-back (F/B) ratio to give sharp bearings.

"While reading the *ARRL Antenna Handbook*," N6WZI says, "I discovered that a parasitic element, cut as a director and placed about .05 wavelength from the driven element, provides a theoretical F/B ratio of nearly 30 dB. I was further surprised to read that at such close element spacing, theoretical gain approaches 5.4 dB. That was an unexpected plus. I kept expecting to find a snag, a problem characteristic. I had never seen this design in commercial or amateur radio use, so I assumed something must make it impractical."

Doug soon discovered that the biggest challenge would be matching a short-spaced yagi to 50-ohm coax. "The closer the director gets to the driven element, the lower the feed point impedance becomes," he says. "There is a negative reactance to be dealt with as well. I explored different feed systems including gamma, T and others. None seemed suitable. Then I read that a U-shaped loop (hairpin) will match antennas with impedances as low as 8 ohms."

Photo B. Doug Lyon N6WZI designed the RDF² antenna described in this article.

A typical hairpin match uses quarter-inch rods with 1-1/2 inch spacing. This approximates a 300-ohm transmission line. N6WZI successfully substituted TV twinlead to make a much more compact feed (**Photo C**). Physically, a hairpin is like a half-turn coil, so it is inductive. This is desirable for canceling out capacitive reactance at the feed point.

I was still unsure how Doug's close-spaced yagi with no reflector could give adequate gain and F/B ratio for foxhunting, so I modeled it with the ELNEC computer program. **Fig. 1** shows two directivity plots. The figure-8 pattern is for horizontal orientation with horizontally polarized signals. There are deep nulls at 90 and 270 degrees.

Turning the antenna to vertical orientation and tracking a vertically polarized signal source gives the outer elliptical pattern. Forward gain and F/B ratio are the same, but 3 dB beamwidth increases from ± 36 to ± 70 degrees. The side nulls disappear, but they won't be missed. Signal reflections from nearby terrain objects tend to fill pattern nulls on 2 meters, so it's best to take RDF bearings using the forward lobe instead of the nulls.

ELNEC assumes that this yagi is in free space. It takes into account the diameter of the aluminum elements and their skin-effect losses. It predicts 17.7 - 54.6 ohms complex feedpoint impedance at the design frequency (146.565 MHz). This is the value that is matched to 50-ohm coax by the hairpin. Gain is above 4.7 dBi and F/B ratio is above 8 dB over the entire 2 meter band.

N6WZI chose 1/4-inch solid aluminum rod for elements. He says, "I used grade T-6061 aluminum at a slightly higher price

because it is less apt to bend than ordinary rod. With such close spacing, construction must be sturdy so that element positions remain constant. I chose 1/2-inch PVC Schedule 40 water pipe for boom and element supports. A block of 3/16-inch thick insulating material such as hardwood or plastic centers the rods in the PVC tee and cross connectors."

The TV twinlead hairpin match is shorted at one end and connected to the two halves of the driven element at the other (**Photo D**). Length is 1-5/32 inches. It must be formed along the boom toward the driven element for lowest SWR. N6WZI measured 1.6:1 SWR at 146.565 MHz. It was under 2:1 over the entire 2 meter band. I tested the RDF² in a clear area and found its F/B ratio to be approximately 14 dB.

You should be able to build the RDF² for under $12 in materials. Overall driven element length is 37-9/16 inches. Director length is 37-3/16 inches. The model in **Photo C** is a special "cutaway" version illustrating how elements are mounted inside the PVC fittings. For a rugged water-resistant antenna, do not cut the PVC junctions. Simply assemble the antenna into the fittings.

Assembly instructions

Cut a 37-3/16 inch length of aluminum rod stock for the director and two 18-5/8 inch pieces for

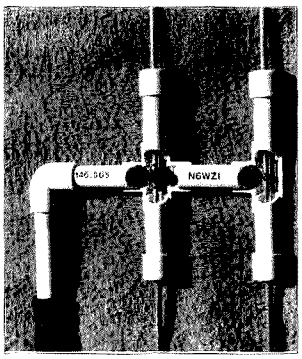

***Photo C.** N6WZI made this special cutaway version of the RDF² to show how it goes together. Each of the six short PVC pipe sections is three inches long. The driven element is in two sections; the gap between them is obscured by the twinlead matching section.*

the driven element. Fabricate two 1 x 1/2 x 3/16 inch support blocks. You will also need 28 inches of 1/2-inch Schedule 40 PVC pipe, one each 1/2-inch tee (T), cross (X), and elbow (L) slip fittings, and PVC cement.

Drill the director rod at its center with a 7/64-inch bit to accept a 4-40 x 3/4-inch screw. Referring to **Photo C** for location, drill a 7/64-inch hole through the PVC T fitting. Feed the director into the T and mount it inside on its support block, similarly drilled. Secure all with a 4-40 machine nut and lock washer. Use a little hot melt glue or household glue to seal the nut in place. Cut two 3-inch pieces of PVC pipe and cement into each end of the T. Drill 1/4-inch diameter holes through the center of two PVC end caps, slide these over each end of the director and cement to the 3-inch PVC pieces. This completes the director element.

Drill each driven element rod section at 5/32 inch from one end with a 7/64-inch bit. Drill the driven element support block with a 7/64-inch bit at 9/32 inches each side of the center. These holes will be 9/16 inch apart, to provide 1/4-inch spacing between the legs of the dipole.

With 4-40 x 3/4-inch machine screws, use the drilled insulating block as a jig. Prepare two solder lugs by trimming the tabs to 1/16 inch. Place solder lugs over the screws and solder the two leads of the unshorted end of the hairpin in place, one to each lug. Now solder on a 64-inch length of RG-58 coax, center conductor to one lug and shield to the other. Trim excess wire and lift off the complete assembly.

With a 7/64 inch bit, drill two holes through one side of the PVC X, using the drilled driven element insulating block as a pattern. Now assemble all the parts (coax, hairpin, solder lug assembly and insulating block) inside the X. Put the screws part of the way through from the outside of the X, then place the insulating block inside and over the screws. Put a dipole end over each screw. Now put the solder lug/coax/hairpin assembly in the X and over the screws, feeding the coax through the X at 90 degrees to the dipole elements. Face the hairpin toward the director element inside the X. Secure all with 4-40 machine nuts and lock washers. Use glue to seal the nuts.

Cut a piece of 1/2-inch PVC pipe to three inches in length and cement it between the director T and the driven X. This provides four inches (.045 wavelength) spacing between the driven element in the X and the director element in the T. Be sure to align the elements parallel to each other. Make the handle from an elbow fitting, 3-inch and 10-inch length of PVC pipe, then cement it in place. The coax goes through the pipe and out the bottom. A bicycle handle grip held with a small sheet metal screw finishes the antenna.

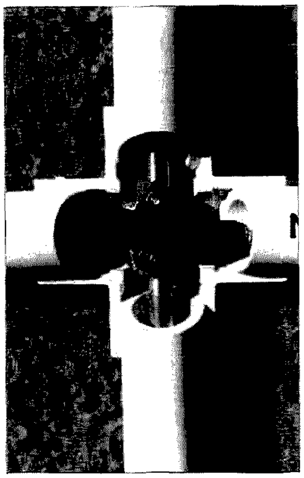

***Photo D.** Close-up of the driven element feed point showing the supporting wood block, coax connection and hairpin match stub.*

A one-afternoon project

The RDF² is so easy to build that it would make a great group project for your club. Plan a short foxhunt soon after the construction party so all builders have a chance to try out their yagis and experience the thrill of finding radio foxes.

As of this writing, N6WZI is not in the antenna-building business, but he is considering making RDF² parts kits available, if there is sufficient interest. Write to him at the address in the sidebar for more information. Please enclose a self-addressed stamped return envelope with your request. (*73* columnists appreciate this courtesy, too.)

A compact yagi is ideal for more than foxhunting. For example, you could use it to pinpoint sources of electrical noise around the neighborhood. N6WZI realized that it might be useful for search/rescue workers seeking aircraft Emergency

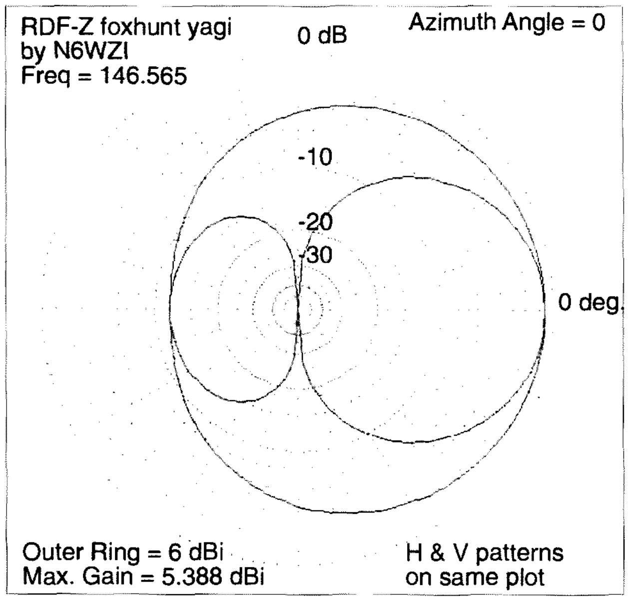

***Fig. 1.** Calculated horizontal and vertical polarization patterns for the RDF². ELNEC shows that its F/B ratio is higher than the classic three-element National Bureau of Standards yagi, which has eight times greater total spacing.*

Locator Transmitters. "I made a prototype scaled to 121.5 MHz for Bob Miller N6ZHZ of the Civil Air Patrol," Doug told me. "Bob used it with such good results that I got a call from a Captain wanting to know how they could get some more. I built another six and shortly after I delivered them, I got a phone message stating that they had been instrumental in the timely location of a downed aircraft."

Caution: For ruggedness in the field, this yagi has rigid elements, firmly attached. When the antenna is oriented vertically, falling on it could cause injury. Children should be trained to hold the antenna so as to minimize this danger. If the user will be running while holding it, attach one-inch diameter solid spheres to the four element ends and wear protective goggles. Always keep safety in mind when foxhunting.

Join me for a weekend of fun at the VHF/UHF Conference. I'll be presenting a slide show Saturday morning on the joys of foxhunting. With any luck, we'll fill the woods with fox trackers Sunday afternoon. I want to hear about RDF contesting in your area, so write and send photos to the address at the beginning of this article. Send E-mail to Homingin@aol.com or 75236.2165@compuserve.com.

This Month's Resources

The 1996 West Coast VHF/UHF Conference will be at Gateway Plaza Holiday Inn, 14299 Firestone Boulevard, La Mirada CA. Conference registration is $15 per person. Saturday night banquet, Sunday morning breakfast, and Proceedings book are available for additional charges. To register, send check to Southern California Six Meter Club, P.O. Box 10441, Fullerton CA 92635. E-mail conference inquiries to rhasting@ix.netcom.com. Call (714) 739-8500 for hotel reservations.

Send RDF² yagi kit inquiries to Doug Lyon N6WZI, 11905 Cresson Street, Norwalk CA 90650.

ELNEC antenna analysis program for PCs is available from Roy Lewallen W7EL, P.O. Box 6658, Beaverton OR 97007. Write for prices.

NEVER SAY DIE
Continued from page 61

even Pons and Fleischmann, the discoverers of the cold fusion effect, have been able to get any patents issued making a claim of over unity energy.

What does this mean to you? Well, that depends on how alive you are. How interested in learning new things. Maybe even trying them. A Manitoba reader called a few days ago to say that when he read about this cold fusion stuff he set up a simple tabletop experiment using nickel. He got 33% excess heat and was hooked. He said he tried gold instead of nickel for the cathode and improved his output by about five times, so now he's heating his greenhouse with a small cold fusion cell.

Well, you can see why I'm excited about this.

Dennis Cravens, a young physics teacher at a small Texas community college (Vernon), is the leading American researcher in the field. His lab cost him under $5,000 over a period of five years. He's recently moved to New Mexico, set up a small lab there, and is working with Dr. Patterson to develop his patented cell. Some business giants are starting to take note.

It didn't hurt when "Nightline" devoted a half hour in early February to interviewing Dr. Patterson. Plus a short interview segment on "Good Morning America."

The Jan. 23rd piece in the *Wall Street Journal* by Jerry Bishop reported on the December Power Gen conference demo by Patterson and Cravens, but kept repeating the old critic refrain that nobody knows why excess heat is happening, and that it is preposterous to claim it is fusion. But then these same hide-bound scientists refuse to accept that fusion is constantly taking place in living cells, so they need to get off their high horses and read more.

I've had to start remembering some of my fundamental chemistry from college. If you fuse lithium and hydrogen you get beryllium plus some lost matter (energy = heat). When you fuse this beryllium with another hydrogen you get boron plus some more lost matter (energy = heat).

Scientists often tend to be so solidly imprinted with what they learned in college that almost no amount of contrary evidence can break through. Max Planck commented on this phenomenon when he proposed quantum mechanics and it was rejected by the scientific establishment. Galileo had the same problem. Nothing has changed. Indeed, I see the same pattern in the medical field. It was this rigid thinking which killed most of the computer mainframe

New Products

Link Plus For Hams

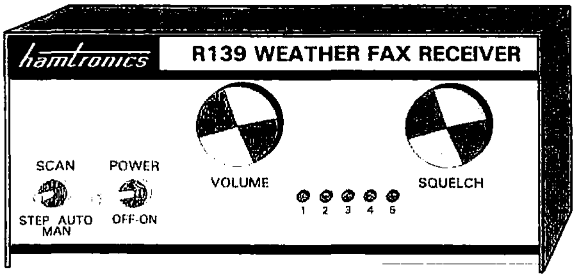
It used to be that you had to have a budget like the Pentagon's in order to afford signal processing equipment such as the LinkMate, but no more. Link Plus Corporation recently introduced the newest member of its family, specifically for the ham radio market.

The LinkMate uses Lincompex technology, in which the transmitter signal is compressed and the receiver signal is expanded, reducing noise and interference.

The marriage of the Lincompex technology and the digital signal processor technology provides a cost-effective alternative for interference reduction previously available only to military and government users.

Government tests have shown improvements ranging from 7 dB to 36 dB, with an overall average of 22 dB under "extremely noisy and unsettled atmospheric conditions."

For more information, contact Link Plus Corporation, 9052 Old Annapolis Road, Columbia, MD 21045. Phone (410) 995-1919. You can also see LinkMate at the Dayton Hamfest, booth #557.



Hamtronics Weather Satellite Receiver

Here's a cheap and easy way to receive weather fax information from the 137 MHz band—the Hamtronics R139 Weather Satellite Receiver. It's a wideband receiver specifically designed for this purpose.

Hamtronics combined the circuitry of the pervious R138/AS138 modules in one unit, with a cabinet and a power supply. Many customer suggestions were also incorporated in the new design.

The R139 is a crystal-controlled unit, with five settings that cover all the popular US and Russian weather satellite frequencies. The crystals are included. The channel can be controlled manually, or the unit can be left scanning for an active satellite.

That way, you can download and record transmissions for later output to a computer demodulator. LEDs on the front panel indicate which satellite is received.

The module form of the kit is just $159; for another $30 you get a 12V power supply and an aluminum cabinet. If you're scared of your solder iron, or don't have the signal generator needed to align the kit, you can buy one wired and tested for $239.

Contact Hamtronics Inc. at 65-D Moul Rd., Hilton, NY 14468-9535, or call (716) 392-9430. Fax: (716) 392-9420. A complete catalog of all the Hamtronics kits, which range from VHF/UHF transmitters and receivers to repeaters, preamps and accessories, is available from the same source.

New HS-1000 All-Band HF Mobile Antenna

Mobile HF operators have a new choice of antennas. High Sierra Antennas has introduced its new HS-1000 all-band HF mobile antenna.

The design incorporates features such as new low-cost mounting options, center-loading coil for high-power and high-temperature applications, a decoupler system, and improved matching system and a remote control panel with limit indicator.

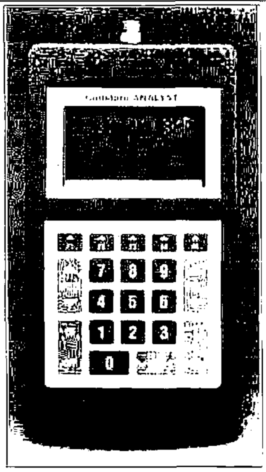
The antenna provides coverage from 3.5 MHz to 30 MHz and beyond without sacrificing performance on any frequency. The variable loading coil is remotely controlled, so the operator can tune the entire HF spectrum without leaving the driver's seat.

The HS-1000 uses two basic mounting systems. The easy-off mount allows the entire antenna to be removed in about 30 seconds for safety or security. This method uses a tapered stud at the base of the antenna together with an upper clamping mechanism.

The new single point mounting method allows the antenna to be attached to horizontal surfaces.

The antenna can be purchased as a complete package, or in its component pieces for those who already own some of the hardware from High Sierra Antennas, Box 2389, Nevada City CA 95959. FAX 916-273-7561 or telephone 916-273 3415.

Check Your Cellular Antenna Performance



Advanced Electronic Applications has released the CellMate Antenna Analyst, a hand-held diagnostic unit that provides comprehensive antenna performance information in an easy-to-read graphic format.

The CellMate covers the 806 to 960 MHz range continuously, graphically displaying antennas' VSWR vs. frequency plots on an LCD screen over a range from 1:1 to 10:1.

The unique LCD readout graphically plots the SWR curve over the entire frequency range, as well as at single frequencies.

CellMate is equipped with a serial interface for use with an IBM-compatible computer. With optional AEA software, users can store VSWR plots obtained by the Analyst in a PC for later reference, comparison or printing. You can even upload plots from the PC to the Antenna Analyst, and the Analyst's functions can all be controlled from the PC as well.

For more information, contact AEA at (206) 774-5554.

Massillon OH 44646

Radio Magic

by Michael Bryce WB8VGE

Let's set the Wayback Machine to 1975, when a very popular construction project was the W4VVF electronic CW keyer. This keyer did all kinds of things that were unheard of then. It sported such goodies as dot-and-dash memory, iambic keying, and solid-state output keying. The keyer consisted of five TTL chips and a handful of other parts. The whole shebang went on one single-sided PC board. There were zillions of these things built by hams. Including me. I had the distinction of assembling one and never getting it to work.

After weeks of troubleshooting, I got so mad at the keyer, I took a three-pound hammer and beat the keyer, ICs and all, into the top of my workbench. While I didn't figure out what I did wrong, I sure had a case of the warm fuzzies after smashing the poogies out of it. To this day, there are still hunks of that project oozing out of the workbench. Ah hah! I hear you saying. So you had The Kit From Hell, too!

Not one to give up, I ordered another PC board and started over again. This time the keyer worked as it should have and I went on to assemble dozens more for various friends and members of the local radio club. What did I do differently the second time around? I asked for help.

As it turned out, there was a mistake in the schematic that caused the bug. Armed with this knowledge, it was a simple matter to correct the error and produce a working keyer. I would have never been able to track down the problem by myself. So, after exhausting all your options, sometimes a note to the company that packed your kit may solve your dilemma. It's always to your benefit to inform the company of a missing step or error in the assembly instructions of the kit. In fact, when you contact the company, they may have several "fixes" available to enhance the operation or assembly of the kit. Don't be afraid to ask for help!

"I got so mad, I took a three-pound hammer and beat that keyer, ICs and all, into the top of my work bench."

Go ahead...touch it

With that out of the way, let's do a little bit of signal tracing. In a receiver, the best place to start is at the input to the audio amplifier. All you need is a fingertip. Of course, don't try this trick if your receiver is being powered by 110 volts. With your fingertip, touch the center terminal of the volume control. If the audio circuits are working as they should, you will hear a load buzz coming from the speaker.

Work your way back toward the antenna. Check for the proper operation of key oscillators such as the BFO and mixers. The VFO should be running as well as the local oscillator. You may need to use a frequency counter or an oscilloscope to check these stages for proper operation. Getting your kit to work takes only a matter of time while working out a few steps in the troubleshooting process.

Projects from the pages

When building a project out of a magazine, it is usually up to the reader to supply all the parts. In some cases, the author may have specified a particular part that not only has the required electrical specifications but also physical characteristics needed to fit the PC board. Usually, the author will have at least one source for all the parts needed to duplicate the project. Be sure that "oddball" part has a source.

Don't forget to check for any software or EPROM that need coding. Without the code, many of the projects won't work. And watch out for prices when dealing with source codes. A programmed micro-processor can be expensive.

73 Amateur Radio Today is one of the few ham magazines that still print the PC board foil pattern and silk screen. Many others request that a letter be sent to obtain the artwork. I suggest you purchase the PC board, if available, and forgo trying to make your own board.

In almost every case, someplace, somewhere, there will be an error in either the silk screen or the schematic. Errors usually happen when drafting the schematic from original artwork to what ends up in the magazine. No matter how many times it is checked for screwups, bugs do get in.

I once had a ham call me and insist that both the magazine that published the article and I had put in errors just so he'd have to buy the next couple of issues. That's just not true. No one wants mistakes to show up in a construction article, especially the editors and the authors!

So, keep in mind there may be nothing wrong with your project, even though it may not work correctly. I'd drop a note to the author. Be sure to include an SASE and ask if there are any errors in the plans.

Since you are your own kit builder when dealing with a construction article, you are free to change values of some parts to match what you have on hand. Unless the author states that certain components must be a specific value, you can change most values without getting into trouble.

Resistors are perhaps the easiest to change. There's not much difference between a 10K resistor and a 12K resistor when used to couple two stages together. The same is true for pull up resistors used to keep a logic high on the output of TTL and CMOS ICs.

You don't get to play with capacitor values as much as with resistors. For one, you don't have as large of selection in capacitor values as you do in resistors. Capacitors are usually selected to provide timing signals, bypassing at specific frequencies and to couple two stages together. Of course, changing the value of a capacitor used in a timing circuit (or oscillator) means the output of that timer or oscillator will be changed.

On the other hand, a capacitor used to couple two stages together can have its value changed without much thought as to circuit performance. If the construction article specifies a 47 pF capacitor, and your junk box yields only 33 pF, that's fine.

As long as you don't stray too far from the published specifications, go ahead and adapt the circuit to suit the parts you have on hand. A good dose of common sense goes a long way when you're building a project from a magazine article.

A 220 Super J-Pole Antenna

Materials List

- 1/2" Copper Tubing (Cut one each of the following lengths): 12.5", 37.5", 25", 1 1/8" (for the cross bar), 1"-2" (for the base stub)
- 26" Length of 3/16" OD copper tubing or wire
- 2" #14 Stranded copper wire
- 1 1/2" Copper elbow
- 1 1/2" Copper "T" fitting
- 2 1/2" Copper end caps
- 2 3/4" Stainless steel hose clamps
- 12" Length of 1/2" birch dowel (for insulator)
- 1 SO-239 Panel mount coaxial fitting
- 1 1/2" Copper threaded fitting
- 1 1/2" Cast iron floor flange
- Tubing cutter
- Screwdriver
- Electric drill and bits: 5/64", 3/32", 3/16"
- Propane torch
- Solder and paste flux
- Electrical tape
- Drill press and small hobby file (both optional)
- Caulking or silicone compound
- 1 1/8" X 1 1/2" piece of thin sheet metal for soldering shield
- Steel wool or household scrubber pad (without detergent)
- Solvent
- Clear exterior spray
- VHF SWR Bridge capable of 225 MHz (borrow, if you don't own one)

NEVER SAY DIE

Continued from page 71

manufacturers and then wiped out most of the minicomputer companies. Where are Wang, Prime, Data General, and the others today? Even mighty DEC is fading away.

It's this pattern which has kept so many people and major companies missing the boat on new technologies. I might mischievously call this the CW mindset.

Our government does it again

One of the cutbacks of government funding has been the Navy research into cold fusion, which was going on in Washington, DC, and China Lake, California. Now, just as cold fusion has proven, even in its early research stages, to be everything promised, the Navy has stopped all further research funding. The Army and Air Force haven't been doing any research at all. Even the Electric Power Research Institute (EPRI) has cut research funding almost totally. Stanford Research Institute (SRI), funded by the Japanese, is moving ahead. Indeed, the Japanese have been increasing their cold fusion research funding every year. The Japanese have also funded Drs. Pons and Fleischmann, the pioneers in the field, and put a total blackout of news on their work.

So it sure looks like we're doing it again, setting ourselves up to lose the biggest industry yet. We lost the audio and videotape industries. We lost the compact disc industry. The TV and camcorder industries. Without any government scientific policy, big business in America is run by next quarter profits, so there's little incentive to invest in any long-range projects. And that's one of the big ways Japan has done so well.

Bio-nucleonics

Scientists have a blind spot when it comes

Number 76 on your Feedback card

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The 73 Flea Market, Barter 'n' Buy, costs you peanuts (almost)--comes to 35 cents a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to: *73 Magazine*, Barter 'n' Buy, 70 Rt. 202N, Peterborough NH 03458 and get set for the phone calls. The deadline for the May 1996 classified ad section is March 12, 1996.

NEVER SAY DIE

Continued from page 56

to anomalies. But I've been complaining to you for years about this, with no hint so far that I'm getting through.

It was my interest in anomalies that got me to follow up on a piece of weird science in the Tompkins-Bird book *The Secret Life of Plants*, which is on my recommended book list. They mentioned that chickens seem to be able to eat silicon and somehow turn it into calcium for their eggs. Transmutation? Shades of alchemy!

So I called Chris Bird and asked him about this. He put me onto a book by Louis Kervran, which was most fascinating. And that led me to Mishio Kushi and his book, *The Philosopher's Stone* (also on my list). All this was just my curiosity at work. I had no idea that it might lead to a possible explanation for the mysterious cold fusion reaction, which has been a matter of controversy for physicists and chemists for seven years now.

As I read these books, which confirmed the ability of living organisms (including chickens and humans) to transmute elements, it occurred to me that this might be what was responsible for all the anomalous heat the cold fusion researchers have been trying to explain.

It didn't take a lot of calculations to show that combining hydrogen and lithium to produce boron would result in a tiny bit of lost mass. We know from Einstein's $E = mc^2$ (where "c" is a huge number) that a little mass is equal to one heck of a lot of energy (heat). Somehow, in the crystal lattice structure of a few metals like palladium and nickel, this transmutation must be taking place. If more atoms were transmuted per unit of time we could have one heck of an explosion, so we're fortunate that Drs. Pons and Fleischmann discovered a very slow reaction.

I proposed this idea to the readers of my *Cold Fusion* magazine, who are some of the world's top physicists and electrochemists, expecting to get flamed for proposing something so dumb. Instead, I've been getting papers from scientists with equations showing how this is probably what is happening. We're waiting for spectrographic confirmation from two universities as to the elemental makeup of used cold fusion cells.

Louis Kervran, many years ago, did an extensive research project in Africa to check on the human transmutation of elements. He measured everything going into a group of men, and everything coming out (ugh!). His reports left no doubt that humans do somehow transmute elements. And this obviously has to result in the generation of some heat. Indeed, this might just turn out to be the major source of heat for us and all other living things. Bio-nuclear reactions. You can learn more about this by reading Kervran's book, *Biological Transmutations*, Swan House Publishing, 1972, 163p; ISBN 0-913010-03-0.

Well, somehow we mammals are turning food into heat. So where in the body is this happening? Where's the furnace? Can the transmutation of elements be the way we maintain our body heat?

In the cold fusion reaction, when we check the cathodes after use, we find microscopic pits. These could be the sites of transmutation, which would generate a lot of heat in a very tiny area as individual atoms transmute and convert the leftover matter into heat. If we find some silver, that would have had to come from palladium plus hydrogen. We'll see.

When I got interested in cold fusion a couple years ago I knew almost nothing about chemistry or nuclear physics. So I started reading everything I could find and asking endless dumb questions. And now I'm able to understand much of the stuff the theoretical physicists are writing for my magazine. I just wish I had the time to set up a small lab and do some research. I'd be surprised if I couldn't generate some high output over input devices using granulated or powdered nickel and a lithium electrolyte.

But then, I wish I had time to learn more about audio compacting algorithms so I could help develop some really narrowband real time audio. Maybe I can get you to do that? And write some articles as you pioneer? Let me put that another way: What have you read and learned in the last month? I've just ordered 30 more books by mail order. I'll let you know if any are really outstanding, and I'm pretty sure some will be.

Are you deaf?

Opportunity keeps knocking and you keep yelling for whoever it is to go the heck away and stop making all that racket. Ray WA2MMT sent me a recent newspaper clipping about a Boston doctor who managed to infect 19 of his patients with hepatitis B, despite wearing gloves while operating on them.

The first letter in the March *73* was from Ray, pointing out that most brands of latex gloves leak after about 20 minutes of use, so there is an opening for a simple gadget which could be connected to the doctor and the patient being operated on to indicate when a glove starts to leak. The medical market is a whopping one. After all, it's a trillion-dollar industry, so medical electronic gadgets command a premium price.

I remember when Wes Schum W9DYV got forced out of his Central Electronics business, a victim of the loss of our whole ham industry in 1964. He went into medical electronics and instead of just barely making a go of it, he was making money hand over fist.

He'd had to sell his small manufacturing business to a larger company a couple years before because he didn't have enough money to keep up with its growth. It all hit the fan when he announced a new rig which cost him about $400 to make. He quickly had thousands of orders on hand and not nearly enough money to buy the parts for that many rigs. The banks couldn't care less about his orders, so he had to sell his business just to keep going.

Then the 1964 "Incentive Licensing" catastrophe hit him, as it did every other ham manufacturer.

When you read Ray's letter in the March issue did you dash to your workbench to see what you could do, or did you ho-hum it and pick up *TV Guide*?

On the bright side for the 19 infected hepatitis patients, and the doctor, if they buy or make one of the Bob Beck gadgets, unless Bob faked a whole stack of lab reports, they'll be able to get rid of the wretched virus in a jiffy. Ditto anyone infected with AIDS and/or HIV.

How difficult can it be to make a gadget which will connect to the doctor and patient and indicate when there's some leakage?

Along the same line, this business of trying to promote condoms as a preventative for AIDS, as I think I've mentioned before, is not as safe as the condom manufacturers would like you to believe. The pores in condoms are much larger than the virus, so they act more as a strainer than a barrier.

Transplants

If you remember my reviewing *The Secret Life of Our Cells* by Robert Stone, you probably weren't surprised at the flurry of talk in the media about a new book claiming that transplanted organs bring along memories from the previous owners. NPR did a segment on it recently.

But this is just what I predicted in my review. My interest in this kind of weirdom started with *The Secret Life of Plants* by Bird and Tompkins, which was published in 1973. A couple of years ago I called Chris Bird to find out what new information had developed since the plants book was published. He suggested I get in touch with Cleve Backster, the chap who did most of the research reported in the book. So I called Cleve and found that his more recent work has been with human cells. The results have been incredible and are described in the Stone book. Both of these books are on my "books you're crazy if you don't read" list. Cleve and other researchers have shown

Antenna Noise Bridge Detector

Tune your antenna, then measure its radiation pattern with this pocket-sized instrument.

J. Frank Brumbaugh KB4ZGC
Box 30 – c/o Defendini
Salinas PR 00751

Using an antenna noise bridge is one of the best and simplest means of measuring antenna characteristics. It is invaluable for tuning an antenna, especially a beam, to resonance at a desired frequency. Normally the station receiver is used with the noise bridge as a detector to indicate the resonant frequency of the antenna, and the resistance and reactance (if any) at the feed point.

The feed point of most antennas, and practically all beams, is high in the air or at the top of a tower. It is extremely unhandy to carry the station receiver/transceiver up a ladder or tower, dragging a long extension cord. All this climbing increases the possibility of falling, which can be detrimental to yourself and whatever you are carrying. Of course, you could make your measurements on the ground, at the end of a multiple of half-wavelengths of transmission line, running up the tower to make an adjustment, then back down and into the shack to adjust the noise bridge and receiver. To make the job easier, I designed this simple-to-build instrument for you.

This detector, used in conjunction with your antenna noise bridge, substitutes for the station receiver. It even fits in your pocket so you can use both hands to climb to the feed point. Measurements at the feed point of your antenna are quick, easy and accurate. Even better, you probably already have the necessary parts in the junk box, so it can be constructed in an hour or two. Even if all parts must be purchased new or surplus, your total expense shouldn't exceed five dollars, not including the enclosure.

How it operates

The circuit is illustrated in **Fig. 1**. The noise output from your antenna noise bridge is applied through a coax jumper cable to J1, an SO-239. This noise, which usually will peak slightly below 1.0 volts, is broadband white noise and is fed through C1, a 100 pF capacitor, to a pair of small signal diodes connected as a rectifier/voltage doubler.

The rectified DC voltage, filtered by C3, a 0.1 μF disc capacitor, is then applied to the base of a small signal NPN transistor Q1, which serves as a meter amplifier. Meter M1 is a small surplus 200 μA meter. It monitors collector current through Q1.

The emitter of Q1 is connected to the wiper of GAIN potentiometer R2, which controls the emitter voltage between zero and about +1.5 VDC. On/Off switch S2 is mounted on the GAIN control which, in series with R3, forms a voltage divider across battery BT1, a 9-volt battery which powers this instrument. The GAIN control is wired so the wiper travels from the end of R3 to ground as the knob is rotated clockwise. This sets the emitter bias and the point at which Q1 will go into conduction as rectified noise voltage is applied to Q1 base.

The current drain from the battery is approximately 8 μA with no input, increasing to slightly over 200 μA with the meter at full scale. With such low current drain an alkaline battery should last for years, even if you forget to turn the instrument off!

Frequency coverage

This instrument covers the range from below 40 meters to above 10 meters in two bands: 40 and 30 meters; and 20-17-15-12-10 meters. Eighty and 160 meters were not included for two reasons. First, there are very few 80 and 160m beams. Second, eliminating these frequencies made band switching considerably simpler, and reduced the cost and complexity.

Bandswitch S1, an SPDT toggle or slide switch, selects the frequency range. The tuning capacitor C2 is a small 150 pF air variable, although one of the small variables with thin plastic sheets between the plates, such as used in many small portable radios, may be used instead. C2, in conjunction with inductances L1 or L2, allows peaking the

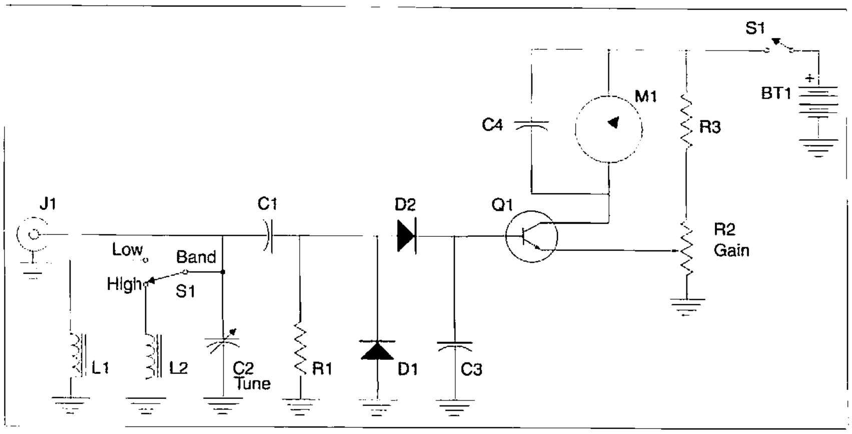

Fig. 1. Noise bridge detector schematic diagram.

frequency response of the instrument in the ham band in which your antenna is to be adjusted. Thus, it readily and handily substitutes for the station receiver, which otherwise would have to be used.

Construction

The detector should be constructed in an aluminum box, or an enclosure made of printed circuit board stock, because it must be well shielded to function accurately. Other than compact construction on a small piece of perf board, or a general-purpose printed circuit board such as are available at Radio Shack™, and short, direct leads carrying RF, parts placement is not important. Only those connections between C1, C2, L1, L2, R1, J1 and S1 carry RF. The other leads carry only DC, so their routing is unimportant.

Although any small 140-150 pF tuning capacitor can be used (take a look in your junk box), an APC type is recommended for compactness. This was a common WW II surplus item and can often be found at hamfest flea markets, or from Fair Radio Sales, Inc., Box 1104, Lima OH 45802. Small surplus meters with 100 or 200 µA movements, originally made for CB and home entertainment equipment, are also available from Fair Radio Sales and other mail order dealers as well as at hamfest flea markets. The toroid cores (T50-2) are available from Amidon Associates, Box 25867, Santa Ana CA 92799, and from Radio Shack. Other components may be found at numerous mail order parts dealers. However you probably can find just about everything you need in your junk box, from other local hams, or at the next hamfest you attend.

Calibration

There are several ways to calibrate this instrument. A source of low level RF covering the ham bands from 40 through 10 meters, with accurate frequency determination, is required. Your station receiver, or a frequency counter, can be used to check the frequency of a signal generator or a dip oscillator.

To calibrate with a dip oscillator, temporarily wind a two-turn loop around L1. Lightly couple the dip meter coil to the link, tuned to a ham band (40 or 30 meters). Be sure S1 is in the proper position. Tune C2 for a dip in the dip oscillator meter. Reduce coupling and tune C2 until the dip is just barely discernible. Mark this spot on the dial of C2. Using your station receiver to make certain the dip meter is on the right frequency will enable you to mark the edges of the wider bands on the dial.

Repeat this procedure with a link on L2 and S1 set for the high band. The 20, 15 and 10 meter bands are wide enough so you can mark both edges on the dial.

You can also use a signal generator to calibrate this instrument, using your station receiver to maintain frequency accuracy because signal generator dials are seldom very accurate. Connect the signal generator output, set for low level, to J1. With S1 set for the low band, tune C2 on this instrument for a peak on M1. Mark this point on the C2 dial. Repeat the process for each ham band.

You can also use your station equipment to calibrate this instrument by feeding your transmitter into a dummy load, or use very low power if you are feeding an antenna. Place a short piece of wire into the center terminal of J1 to act as an antenna. Key the transmitter on CW (key down) and tune C2 for a peak on M1. Mark this spot on the C2 dial.

Operation

This device can be used to replace the station receiver when adjusting an antenna. It can also be used as a linear field strength meter to measure the field around the antenna and plot its radiation pattern.

Operation as a noise bridge detector

Connect a short length of coaxial cable between J1 and the "receiver" connector on your antenna noise bridge. Connect the "unknown" connector on the bridge to the feed point of your antenna.

Tune the noise bridge detector to the ham band of interest. Then follow the directions in your antenna noise bridge manual and adjust your antenna, substituting the noise bridge detector wherever "receiver" is mentioned in the manual.

Measuring antenna radiation pattern

After you have adjusted your antenna you can use this instrument as a linear field strength meter. Connect a short antenna or a remote dipole to J1. With low power applied from your transmitter to your antenna, enough to register on the meter of this instrument, either rotate the beam to check its radiation pattern, or move the detector and its antenna around the antenna, noting the meter indications at each point. The distance between the station antenna and the detector or its remote antenna should be several wavelengths at the frequency in use for greatest accuracy.

When used to indicate field strength, the lower fifth of the meter scale will be nonlinear because of diode conduction knees. However, the upper 80% of the meter scale provides linear indications, so increases and decreases in the meter indication in this upper scale portion indicate equivalent changes in radiation intensity from your antenna.

Caution!

This instrument is extremely sensitive. It is easy to pin the meter when using it in conjunction with your antenna noise bridge, and also during the calibration procedure. Use the GAIN control as necessary to keep the meter needle from wrapping itself around the pin! 73

Parts List

BT1	9-Volt alkaline battery
C1	100 pF mica or poly capacitor
C2	140-150 pF variable capacitor (see text)
C3	0.1 µF disc capacitor
C4	0.01 µF disc capacitor
D1,D2	Germanium diode: 1N34, 1N60, 1N90, 1N270, etc.
J1	SO-239 UHF female connector (or builder's choice)
L1	33 turns #26 enam. wire on T50-2 toroid (40-30 meters)
L2	11 turns #26 enam. wire on T50-2 toroid (20 through 10 meters)
M1	100 or 200 µA meter (see text)
Q1	NPN small signal transistor: 2N2222, 2N3904, 2N4124, etc.
R1,R3	10k 5% 1/4 Watt resistor
R2	1000 Ohm linear taper potentiometer, with switch S2
S1	SPDT toggle or slide switch (Bandswitch)

Carr's Corner

Analog-to-Digital (A/D) Converters

Joseph J. Carr K4IPV
P.O. Box 1099
Falls Church VA 22041

Amateur radio astronomy has been a long-time favorite topic in this column. I've discussed the topic of frequencies from near-DC to daylight (literally!), but there always seems to be more to say. One constant question, however, is how can one collect the (essentially) analog data that results and store it in a computer? The answer is to use an analog-to-digital converter (ADC or A/D).

How the DC signal is derived

The receiver used for radio astronomy observations, whether VLF, HF, or VHF, will produce a varying signal level according to the strength of the received signal. It is that signal level variation that you want to record. This job requires that the signal be converted into a DC voltage; or, more correctly, a unidirectional varying signal that looks a lot like unstable DC.

This is done by using a rectifier and integrator circuit. Like most things, we can do this plain or fancy, depending on how you want it and what you want to do. **Fig. 1** shows the plain solution that I learned from Bob Sickles and Jeff Lichtman. It uses a plug (P1) to the speaker or headphones jack of the receiver. Once the receiver is tuned to the frequency being observed, the plug is inserted so that this circuit comes into play. The rectifiers consist of a half-wave voltage doubler made up of C1, D1 and D2; C2 is also part of the voltage doubler, but it serves a dual role as the integrator. Capacitor C1 can be a 1 µF tantalum, or some other form. If the capacitor is a polarized variety, then the polarity as shown should be observed. The diodes are plain vanilla 1N60 germanium diodes. These diodes are also sold by some dealers under the designations ECG-109 and NTE-109 (these are intended for the radio and television repair industry).

The integrator consists of C2 and R1. The time constant of the integration can be varied by changing the values of C2. I've used values from 10 µF to 470 µF with only a small observable change in the way it operates. The output signal is a DC voltage or current that goes to a meter, an oscilloscope, strip-chart recorder, or the input of an ADC.

The fancy approach is shown in **Fig. 2**. This circuit is a *mean value amplifier*, and is made from circuits seen in most good operational amplifier books, including my newly released (March 1996) title from Butterworth-Heinemann (313 Washington Street, Newton, MA 02158-1626; 1-617-928-2500). The book was released in England, but is available in the USA through the address shown. What is a mean value amplifier? Well, it's really just a rectifier/integrator writ large to justify using the op amps.

Amplifier A1 is a precise rectifier (half-wave), while A2 is a Miller integrator. The op amps can be CA-3140s (which use 741 pinouts), or a single CA-3240 (two 3140s in a single DIP with the pinouts of the popular LM-1458 device). The values of the resistors are not critical, but the ratios (R and 2R) should be followed. 5k ohm and 10k ohm, or 10k ohm and 20k ohm are likely candidates for value. The diodes are germanium 1N60s, although I've used silicon 1N4148 with no observable problems. The integrator time constant is R times the value of the capacitor. Start with 1 µF and work up 'til you get a good response. The compensation resistor between the (+) input of A1 and ground should have a value of R, or that input can be grounded if some small DC offset can be tolerated (try it first, however, because integrators like A2 don't like offset voltages at their inputs).

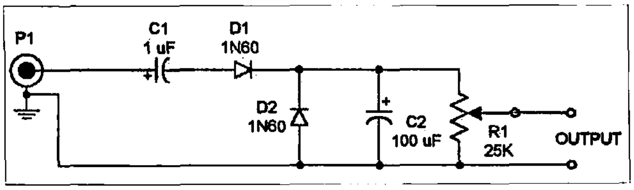

Fig. 1. Plain vanilla rectifier/integrator.

A/D converters

The job of the ADC is to take an analog input voltage and render it into a binary word that represents it. Cheapo converters that divide up the analog input voltage range into 256 states are available in 8-bit lengths A 12-bit converter costs a little more, but can divide up the analog voltage into 4,096 different values. In the 12-bit case, on an ADC that allows analog input voltages from 0 to 5 volts, 0 volts might be represented by binary 000000000000, while +5 volts would be represented by binary 111111111111. Actually, because of the 1-LSB and zero problem, the maximum input voltage would be only (4,095/4,096) x 5 volts, or 0.9998 x 5 volts = 4.999 volts.

One approach to the ADC problem is to build one yourself. The Maxim people seem to have a lot of really interesting circuits, one of which is their MAX-187 ADC. It comes in an 8-pin mini-DIP package, and offers 12-bit conversions and a serial output. The circuit of **Fig. 3** uses a MAX-187 and is connected to the computer via the parallel printer interface. The parallel printer interface is normally regarded as an output because it sends data to the printer, but there are five handshaking and signaling lines on the interface connector that either go back to the computer or are bidirectional. Wire the connector as shown, and then plug it into the printer output at the back of the computer. Make sure that the gender of the connector that you use is opposite that of the parallel printer output (otherwise, it's still a DB-25 connector).

You will have to write a short BASIC program to input the data. I have a candidate program, but it belongs to someone else. If you send me an SASE or reach me via E-mail, I'll tell you where to get the BASIC listing that runs this ADC.

The MAX-187 can be bought in single quantities from dealers such as Digi-Key (701 Brooks Avenue South, P.O. Box 677, Thief River Falls MN 56701-0677; 1-800-344-4539). By the way, if you're at all interested in electronic construction projects you need the Digi-Key catalog. It is chock full of neat parts; there's not a lot in the RF realm, but it offers nearly everything else (and they do have at least some RF parts). They are a source of the NE-602 chip used for a lot of direct-conversion radio receivers, for example.

Photo A. Pico Technology, Ltd ADC-16 serial port ADC.

Another solution is to buy a ready-made ADC from a commercial source. Several models are available that plug into either the parallel printer port or the RS-232 serial asynchronous communication port on the back of the computer. **Photo A** shows one that I bought from Pico Technology, Ltd. (Broadway House, 149-151 St. Neots Road, Hardwick, Cambridge CB3 7QJ, England). They take Visa cards, so you can order and not worry about sending a check (or as they say, "cheque") denominated in pounds sterling.

The version shown in **Photo A**, is the Pico ADC-16 model (although I understand a newer version is now out). It has eight software-selectable analog (or "analogue") inputs, resolution that is programmable between 8 and 16 bits, and a 12.5 volt input range. Pico Technology, Ltd. also offers two software programs for MS-DOS and Windows computers that allow you to run their various ADC products. PicoScope makes your computer work like a storage

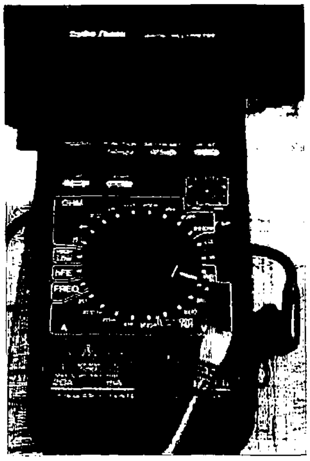

Photo B. Radio Shack computer-interface digital multimeter.

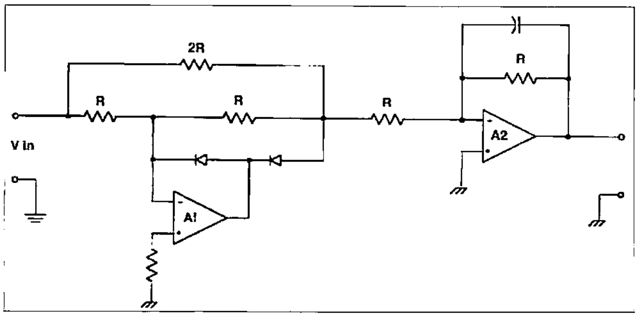

Fig. 2. Fancy rectifier/integrator (or "mean value amplifier").

oscilloscope when the ADC is connected, while PicoLog makes the computer into a nifty data logger. I use both software packages.

The final method, shown here in **Photo** B., is the Radio Shack™ digital multimeter that interfaces to IBM-PC compatible computers through the RS-232 serial port. The advantage of this device is that it also functions as a combination frequency counter (although not to a high frequency) and digital multimeter, when not being used for ADC. Also, because of the different ranges and functions, a wider range of parameters can be input to the computer. The Radio Shack instrument also comes with its own software for MS-DOS or Windows machines.

The Radio Shack computer-interface digital multimeter comes in a couple of different models. The one I bought is not easily found anymore; however, the manager of my local Radio Shack told me that he stocks a couple of varieties that replaced it. Check with a Radio Shack store to see whether or not this is a good idea for you. I paid around $130 for mine, but don't know what the current price is.

The use of the computer allows you to make a lot more observations, as well as do some neat data analysis that would be harder by hand. Strip-chart recordings look like "real science" but are a pain in the neck to read and use properly. I prefer the computer approach, if only for that reason.

Note: If you write a BASIC or Visual-BASIC program to read data from any sort of ADC, and want to time and date stamp the data using the computer's internal clock/calendar, then make sure that you store the data in a file in comma-delimited format. This means putting a comma "CHR$(0)" character between "print#" statements for the ADC data, time and date. If you do it right, then you can display the data through an Excel, Lotus 1-2-3, or other spreadsheet program. Also, the graphing functions of those programs can be used to plot your data if the ADC software lacks its own version.

Connections

I can be reached at P.O. Box 1099, Falls Church VA 22041, or via Internet E-mail at carrjj@aol.com. I welcome your input.

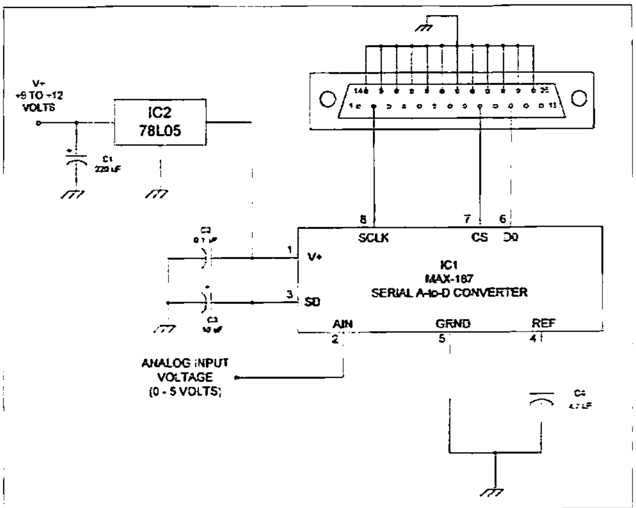

Fig. 3. MAX-187 ADC to plug into parallel port of a computer.

NEVER SAY DIE

Continued from page 77

conclusively that all of our cells are in some way in communication with each other, no matter where they are. Which raises some interesting questions when it comes to organ transplants and blood transfusions.

It also ties in with the work of Antoine Béchamp (1812-1908), who opposed Pasteur's theory of microbes causing illness. You can read *Pasteur Exposed, the False Foundations of Modern Medicine* by Ethel Hume for the gory details of Pasteur's fakery. And the work of Royal Rife (1888-1971), as reported in *The Cancer Cure That Worked* by Barry Lynes. Rife's amazing microscope allowed him to see the most fundamental of life forms, just as Béchamp's had. And as Gaston Naessens (1924-) did with *his* super-powerful microscope. Naessens called these smallest of life forms somatids. And he found that they could survive freezing and 200°C. They were impervious to any acid, to nuclear radiation, and not even a diamond knife could cut them.

Béchamp was able to see them with his microscope by viewing cells using sunlight for illumination. This caused them to fluoresce and become visible. Rife did it by beating ultra-violet light against their UV light and viewing the mixing product of the two light frequencies.

Naessens found that when he injected the somatids from one rabbit into another he could make skin grafts to the second rabbit that would not be rejected. He tried this with humans and again there was no rejection. But the Canadian government and the medical association were so busy trying to put Naessens in prison for curing people of cancer (1989) that he couldn't get his research papers published. I reviewed the book, *The Persecution and Trial of Gaston Naessens*, by Chris Bird, some months ago. Of course it's on my recommended book list.

So much for transplanted organs staying in touch with the original owners, even after death. That brings up the question of memory, where very little research has been done. Somehow our cells seem to be able to contact our memories.

While most of us, when we are reborn, have our past lives erased from our memories, reincarnation investigators have found that many young children have memories of previous lives, but these fade away by the time they are around three. I've never had much problem helping almost anyone contact their past lives under hypnosis, often with great clarity. I found, as have many other therapists, that events in previous lives can sometimes have a considerable impact in one's current life. It would be interesting to regress someone with an organ transplant and see if there are contactable memories via the new organ. Ditto even blood transfusions.

The next step might be to develop people's ability to contact these memories. Might we eventually be able to give people transfusions of blood from hundreds of people with knowledge and skills in a wide variety of fields? How about becoming a concert pianist via a transfusion? Yes, I know, I'll probably get a bunch of letters from Techs asking where they can get some blood from a high speed CW op. Anything to keep from having to actually sit down and spend a few hours training their minds to get their hands to write letters when their ears hear the code sound patterns.

Walking out

Instead of telling me about your antenna and rig the next time we meet on the air, how about telling me about any outstandingly good movies you've seen recently? Sherry and I have walked out on two serious turkeys recently, despite one of them getting thumbs-up reviews and several OSCAR nominations.

You might also tell me what TV shows you find particularly interesting. I'd hate to be missing anything outstanding, which I doubt I am. Most of the stuff on TV is instantly forgettable and the time better spent contemplating one's navel. Or watching paint dry.

For a couple of seasons I really enjoyed "Picket Fences," but the writing took a serious nose dive this season. Something has gone terribly wrong there. Ditto "Roseanne," which used to have writing verging on genius. It's turned blah too. "Law and Order" has been

Continued on page 82

NEVER SAY DIE

Continued from page 81

continuing with its unpredictable plot twists, despite some cast changes. "Murphy Brown" started out pretty good, but ran out of steam a year ago. "Strange Luck" has been pretty good, but it's been canceled. Not much else I've checked out has. Oh, I enjoy Chief Inspector Morse in the "Mystery" series. And I save any magic specials that come along. Love those.

"Homicide" and "NYPD Blue" started off pretty well, but they got more and more wrapped up in developing the characters instead of the crime stories, turning them into soaps. The writing on "The Simpsons" is cleverer.

I save a lot of viewing time by taping everything first. I zip through the commercials, and ditto anything boring. I tape several of the magazine shows and zip most of them, slowing down for exposé segments. I prefer not to waste time gawking at OJ and the usual sob-sister fluff. News? If it's important it'll be covered in *Newsweek*. The rest of it is like gawking at road accidents.

I do most of my TV viewing while I'm eating meals, since I wouldn't be able to read or write then anyway. So my actual TV-only viewing time is minimal. Even so, it seems to be beating most of the movies I've gone to see. I guess my favorite for last year was "Babe." I'd rather spend more time reading, writing, and maybe even some time to get on the air.

Fluoride HI

My apologies for harping on this, but I just heard from one of your friends that despite my fluoride editorial last month you are still drinking city water. Do you really want to chance ending up as Alzheimer's veggies in a nursing home? Yes, Chicken Little is pecking at your door.

A reader sent me still another report on water fluoridation research. It turns out that even a small amount of fluoride in the water tends to leach out lead, copper and iron from water pipes, increasing their toxic effects. In fact, the total toxicity of the combinations is much greater than their sum. Sodium and aluminum fluoride cause irreversible memory loss, dyslexia, behavioral and learning problems. Just what your kids need. Of course we're solving that problem by sedating 'em with Ritalin.

Fluoride exposure during pregnancy retards brain development, lowering the child's IQ. That what you want?

My mother died of Alzheimer's, so perhaps I'm being over-protective of your health. I sure wish I'd known 30 years ago what I do now, but it never occurred to me that the government might do something so harmful to our health as this. Or that doctors, many of whom must have found out about this, would contribute to the conspiracy of silence. Up until I started reading about health care as part of my homework for the New Hampshire Economic Development Commission a few years ago, I believed in doctors, just as most of you do. I sure got a rude awakening.

If you run short of something to talk about on the air you might pass the word. And please keep your eyes peeled for any clippings I may have missed.

LETTERS

Continued from page 46

confident in saying I have similar opinions to many "no-code Techs." Since I am in amateur radio for fun, I refuse to be bullied into jumping through hoops to upgrade. I have no interest in Morse code. To steal a phrase from a soft drink commercial, "never had it, never will." It simply makes no sense to require code proficiency in operators who will never use it. I have no problem with operators who enjoy CW. That is what they like. I enjoy repeaters, FM, public service, and packet. I wouldn't expect anyone who had no interest in packet operations to demonstrate packet proficiency.

I would like to operate HF because I could pass traffic from other areas of the world experiencing disasters. This past hurricane season highlighted the need for services like this. Who gains when an eager operator is prohibited from performing public service work due to lack of code proficiency? How about the people in affected areas? This makes losers out of the amateur community as a whole. Public service is the strongest argument for amateur radio.

Escalating difficulty levels through the theory and practices sections of the test makes sense because we all use theory and we all had better know the rules. CW subbands are good because they give operators who enjoy CW a place to have fun. Let's face it, when it comes right down to it, code is being used to keep "the riffraff" out. If there is such a need, make the written tests harder. Keep it relevant. There is also probably an element of "I had to do it, why shouldn't you?" Ridiculous! Until we get past this absurd idea that proficiency in an antiquated form of communication must be a rite of passage, the lack of activity in the upper license classes will continue. Even the military has recognized the uselessness of code and phased it out. At one time CW had its place. In an era before the high quality electronics and alternate modes of today, CW may have been the only mode that could be pulled out of the noise. This no longer applies. Hams have always been progressive when it comes to equipment. Too bad we can't say the same about licensing. People in a hobby will do what is fun and forget the rest. When the ARRL realizes this I will upgrade, and probably not before.

Hey Mike, you troublemaker, you've got the germ of a really good idea there! Since the code is considered so important by the old-timers, not only should they be retested every year to make sure their code skills haven't deteriorated, they should also be forced to demonstrate packet, RTTY, and slow-scan skills...Wayne

Pete Sedler, Georgetown OH. Even though you've got an 84-page booklet of your as yet unpublished editorials, would you please discuss in *73* how to become an entrepreneur? I don't mean learning marketing, PR, budgeting, accounting, etc.; I mean how do you change from the employee mindset to the boss mindset? When I suggest to my always-broke fellow employees that they think of starting some kind of small business, they look at me as if I'd just beamed down from the mother ship. When I tell them I've started learning about the Internet in order to start a business, they edge away. They like to complain, but where has the old American pioneer spirit gone? An article in the paper said Baby Boomers are planning on using their paychecks from age 50 to 65 to finance their retirement, but with corporate downsizing, their careers will probably be over by the time they're 58.

Pete, if people were any good at planning ahead they wouldn't smoke, drink, get amalgam fillings, eat coffee and Danish for breakfast and burgers and fries for lunch...Wayne

Helen Clancy - XYL VK3DC. My husband David thrusts your wide-ranging and excellent editorials under my nose nearly every month. Your "Chef Green" November editorial prompted me to write. Indeed, you inherited a tasty coleslaw dressing from your grandmother. We tried it! But not simply on boring old cabbage. To the finely shredded cabbage we add shallots or spring onions, capsicum, green and red pepper, celery, and grated carrot. You can also add some diced apple, corn kernels, sultanas, cooked peas, pine nuts, and diced raw mushrooms. In our climate, four or five months of the year are salad delights. As you say, raw is healthy. And delicious. Keep the creative thoughts flowing. Oh yes, I love your contract.

You're right, Helen. I too enhance my coleslaw. The dressing also makes a marvelous dip for fresh veggies. I use it every day...Wayne

Bill Chatterly N1SGI. Since I'm a satisfied user of Computer Aided Technology's *Pocket Morse Trainer*, I was happy to see the ad for it in your magazine. I've passed my 5 and 13 wpm tests and expect to pass the 20 wpm test soon, but there's more. After seven months of use, the unit stopped working. I thought it might have been my fault, so I shipped it back, saying I'd pay the repair costs or the cost of a new Trainer, since I sure didn't want to be without it. Within 10 days I received a brand new Trainer...no fuss, no charge. My thanks to Computer Aided Technology. Thanks, also, to *73* for the many excellent articles you've published. I'm glad I subscribe.

Ed Fowler KC4RIY. I enjoy your magazine and your editorials. Your projects are great and do not have the voodoo that *QST* and *CQ* have. Keep it up.

Sure, Ed, but you can help. Whenever you run into anyone on the air who's built something that sounds interesting...like maybe an antenna that's working like gangbusters...get after him to write it up for us...Wayne

Tom McLaughlin, Mango FL. We are trying some of the remedies from your Nov. editorial and they seem to be working! My dentist, who is a very smart person and a stealth health nut, hasn't said anything about mercury fillings, but he has quietly been replacing my fillings with crowns. A recent article on ozone references gas vapors released during vehicle fueling. Maybe you've seen the very tiny federal warning stickers on gas pumps. If the truth was ever let out, I'm sure we'd see that Freon™ causes less than a hundredth of the ozone reduction that gas vapors cause. There is very little of anything in the air that matches the carcinogenic power of raw gas vapor, with its benzene and toluene components. Vehicle fueling should be done with vapor-tight fittings, like those used for propane. The cancer rate would probably start to go down immediately.

Another troublemaker...Wayne

Michael Smith WD4KMP/5. Two names stand out from my early years: Gernsback and Green. Thanks for four decades of entertainment and information. Three decades ago I developed painful ulcers. Gallons of Tagamet and such provided only temporary relief. But I got lucky...I contracted something much worse. After great quantities of various drugs I was "cured" and...surprise!...the ulcer was gone. This of course proves to me your idea of ulcer causation and cure. And reaffirms my "faith" in the AMA. Microbes, little critters which we can't see, right on down to viruses and even sub-viral "living molecules" cause us various cancers, rheumatoid arthritis, and a variety of illnesses. Internal medicine, as practiced today for profit, does just that: It generates more profit than health, just as you say.

The AEC said on TV recently that 3000 people die each year from cardio-pulmonary disease caused by burning fossil fuel. Disregarding their particular pecuniary interest in such stats, that's still not as dangerous as the cheeseburger and even less deadly than the automobile. But little is said of the things which cause 95% of us to die from other than old age because these things are not emotionally arousing. Is there a cure for *this* disease?

Wayne, you cost me $5 for the wonderful Roche tape, "The Fall of the Ivory Tower."

Ulcers? Lordy, read the $15 book, "Your Body's Many Cries for Water." A few glasses of water will quickly end ulcer pains. Are the millions of Alzheimer veggies ending up in nursing homes merely the product of years of dehydration? Mike, the "health industry" is just as crooked as all the other big businesses. I would be most interested to learn of any major industry that isn't crooked. Meanwhile, if any reader knows of a way to get people interested in living longer, please let me know. I've found almost everyone angrily resistant to any efforts to help them live longer and healthier... Wayne.

QSL Contest

Did you buy your QSL off a rack, or did you put some thought and creativity into it? If you think you have a winner, send it in and let us have a look at it. Who knows, it might make the cover. Well, maybe page 85 or so. Or maybe Wayne's wastebasket. If it's declared a winner, you'll get a CD of your choice of any of 26 kinds of music, as listed in Wayne's November editorial. You'll also see it in 73!

Send it to:

QSLContest,

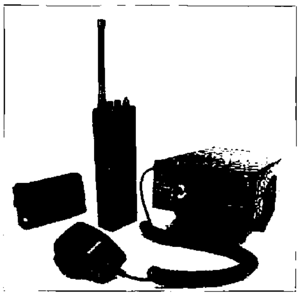
Presto-Change-O: New "Jerk and Run" Bendix King Radios



When you're in your car, it's a mobile unit with an RF amplifier, and when you leave your car behind, you take out the module and it's an HT.

That's the idea behind the new line of Bendix/King Jerk & Run radios. The ECH59 0JA and ECU49 0JA models include a 50-watt broadband amplifier. In addition to increasing the output of the units, the EC series allow any Bendix/King VHF or UHF portable radio to be inserted into a metal housing that charges the battery. The Jerk and Run feature allows the user to flip a lever and eject the radio with a spring-loaded mechanism and take the unit away for portable use.

BK Radio, Inc. can be reached at 2901 Lakeview Road, Suite 100, Lawrence KS. 66049. (913) 842-0402; fax (913) 841-0287.

Manufacturers: If you have a new product and want it considered for review in 73, please call 603-9240058.

SPECIAL EVENTS

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the April issue, we should receive it by January 31. Provide a clear, concise summary of the essential details about your Special Event.

APR 28

BUDD LAKE, NJ The Northwest Jersey Hamfest will be held at the Budd Lake Firehouse, Route 46, rain or shine. Open at 6 AM to sellers; 8:30 AM to buyers. Talk-in on 146.520. Call *(201) 584-6550 days; (201) 770-0242 eves.*

MAY 4

CADILLAC, MI The Wexaukee ARC will hold their annual Hamfest 8 AM–2 PM at the Cadillac Middle School. VE Exams for all classes at 1 PM. Talk-in on 146.98 Rptr. Contact *Dan KE8KU, Wexaukee ARC, P.O. Box 163, Cadillac MI 49601. Tel. (616) 775-0998.*

FRESNO, CA The Fresno ARC, Inc. will hold its annual regional HamFest at the Riverland RV Park. Gates open at 7 AM and festivities last all day. Free camping Fri. night, May 3rd. For more info, listen to the Club's Sun. night Net at 7 PM on the Club's Rptr. at 146.940(-); or call *John Pritchett WA6JWK at (209) 222-6793.*

GREENVILLE, SC The 1996 Greenville Hamfest, sponsored by the Blue Ridge ARS, will be held 8 AM–5 PM at Anderson County Fairgrounds. Talk-in on 146.01/.61 or 146.22/82. Walk-in VE Exams at 12 noon. Contact *Jeff WA4EFT* or *Kay KE4NHX Borke* at *(864) 967-3284 after 6 PM, EST. E-mail: 102431.2306@compuserve.com; or mail to 403 Aster Dr., Simpsonville SC 29681.*

SIERRA VISTA, AZ The Cochise ARA Hamfest will be held at the club's site on Moson Rd., beginning at 7 AM. VE Exams on-site. Talk-in on 146.76(-). Contact John or Leatha Braden, 2200 Sonoita Dr., Sierra Vista AZ 85635. Tel. (520) 459-7960.

MAY 4–5

ABILENE, TX The Key City ARC, Inc., will host the ARRL West Texas Section Convention and the Key City ARC Hamfest. Setup for dealers and manufacturers will be Fri., May 3rd, 4 PM–9 PM. Set-up for all others, including dealers arriving late, will begin at 6 AM Sat. May 4th. Contact *Peg Richard KA4UPA, Hamfest Chairperson, Key City ARC, Inc., PO Box 2722, Abilene TX 79604. Tel. (915) 672-8889.*

MAY 5

BEMIDJI, MN The Paul Bunyan ARC will hold its annual Hamfest at the Northwest Tech. College, 8 AM–2 PM. Talk-in will be on the 146.73 Rptr. VE Exams. Flea Market. Contact Roben Beyer, *P.O. Box 524, Bemidji MN 56601. Tel. (218) 751-4801;* or *e-mail emilee@northernnet.com.* Individuals wishing to test must pre-reg. with *Gurnee Bridgeman, (218) 243-2002.*

DECATUR, IL The Richland Comm. College, Corner of Reas Bridge Rd. and Brush College Rd., will be the location for a Hamfest being sponsored by the Cenois ARC. Outdoor Flea Market open at 7 AM. New Vendor Area inside. VE Exams at 9 AM, walk-ins only. Talk-in on 146.730(-) PL 123.0; and 442.250(+) PL 123.0. Contact *Decatur Area Hamfest, P.O. Box 4595, Decatur IL 62525: or call Bert Ruble at* (217) 423-0314.

WRIGHTSTOWN, PA The 22nd Annual Hamfest of the Warminster ARC will be held at the Middletown Grange Fairgrounds, Penns Park Rd. starting at 7 AM. Setup at 6 AM. Computer hardware and software vendors are invited to participate. Talk-in on 147.69/.09 Rptr., and 146.52 simplex. VE Exams at 11 AM. Pre-reg. begins at 10:30 AM. Applicants bring original and one copy of present license and/or certificates of successful completion (if any): two forms of ID and the $6.05 exam fee (Novice class exams are free). Contact *George Brechmann N3HBT, at (215) 443-5656, 9 AM–9 PM.*

MAY 11

MANITOWOC, WI The Mancorad RC will hold their 1996 Hamfest and Computer Swapfest at Manitowoc County Expo Ctr. on County Hwy. R. Flea Market (amateur, computer, electronic). VE Exams (all classes) at Silver Lake College (Hwy. 151). Test reg. closes at 9 AM. Talk-in on 146.01/.61. Contact by sending an SASE to *Mancorad RC, P.O. Box 204, Manitowoc WI 54221-0204;* or call *Red (414) 684-9097 days; or Glenn (414) 684-7096 day or eve.*

MAY 17

SOUTHWEST OH The Southwest Ohio Chapter of the Quarter Century Wireless Assn. will hold its 1996 Annual Banquet in conjunction with the Dayton Hamvention on Fri., May 17th, at Alex's Continental Restaurant. C.O.D. bar at 7 PM; Banquet at 7:30 PM. Reservation deadline is May 15th. QCWA membership is not a requirement. Tickets $15 ea. Make check payable to *Robert L. Dingle, Treas. Chapter 9,* and mail to *1117 Big Hill Rd., Kettering OH 45429-1201.*

MAY 17–19

DAYTON, OH The 1996 Dayton Hamvention will be held at the Dayton Hara Arena and Exhibition Center. For Exhibit info, call *(513) 276-6931;* for Flea Market details, call *(513) 276-6932.* Talk-in on the DARA Rptr. 146.94(-), alternate 146.91(-). Dayton hams also monitor 223.94(-) and 442.1(+). Sponsored by the Dayton ARA, Inc.

MAY 18

EPHRATA, PA The Ephrata Area Rptr. Soc. will hold the 11th annual Hamfest starting at 8 AM at the Ephrata Sr. H.S., 803 Oak Blvd. VE Exams will be given. For info and table reservations, write *E.A.R.S., Inc., 906 Clearview Ave., Ephrata PA 17522,* or call *Bill N3PZA after 6 PM at (717) 484-2102.*

FORESTDALE, RI The Rhode Island Amateur FM Rptr. Service, Inc., will hold their Annual Spring Auction and Flea Market at the VFW Post 6342, Main St. The Flea Market opens at about 8 AM. An Auction will be held 11 AM–3 PM. Talk-in on 146.76. Contact *Rick Fairweather K1KYI, 144 Parkview Dr., Pawtucket RI 02861;* or call *(401) 725-7595 between 7 and 8 PM.*

MAY 18–19

YAKIMA, WA The ARRL Washington State Hamfest will be hosted by the Yakima ARC (W7AQ). Sat. May 18th, 9 AM–4 PM; Sun. May 19th, 9 AM–1 PM. Commercial dealers. Flea Market. VE Exams. Talk-in on 146.06/.66 PL 123. Contact *Larry Sieger KI7JL, 13112 Douglas Rd., Yakima WA 98908. Tel. (509) 966-5117 eves.* This event will be held at Selah Middle Sch., 411 N. 1st St., Selah WA.

MAY 19

SACRAMENTO, CA The North Hills RC will hold their Annual Radio Swap and Electronics Fair from 7AM–Noon at the Carmichael Elks Lodge, 5631 Cypress Ave. Carmichael CA. Talk-in on 145.190(-) and 224.400(-). Contact *Tim Lewis KD6FWD at (916) 722-7037;* or write to *NHRC SWAP, P.O. Box 41635, Sacramento CA 95841-0635.* Internet http://www.ns.net/~NHRC.

MAY 31–JUN 1

SO. SIOUX CITY, NE The ARRL Midwest Div., and the ARRL Dakota Div. will combine for the Midwest-Dakota-Hamboree Convention. The 3900 Club will host this event. A special luncheon aboard the Sioux City River Boat "Belle" is planned for the ladies on Sat., as well as other programs for XYLs. VE Exams. QCWA Luncheon and meeting. Wouff Hong ceremony. Flea Market. A Fri. night dinner has been arranged as a special fun night. Please request a flyer from *Dick Pitner WØFZO, 2931 Pierce St., Sioux City IA 51104.* The convention will be held at the Narina Inn on the Missouri River.

NASHVILLE, TN The Nashville ARC, Inc. will sponsor "Hamfest Nashville" on June1st at the Tennessee State Fairgrounds. Open to the public at 8 AM. Open to vendors from noon–11 PM Fri. May 31st; 5 AM–7 AM Sat., Jun. 1st. For table reservations, contact *David Scott KK4WZ, (615) 736-7855 days, or (615) 356-2929 eves.*

JUN 1

BANGOR, ME The Bangor Hamfest will be sponsored by the Pine State ARC at Hermon

H.S., 0800–1300 hrs. Flea Market. Dealers. VE Exams. Campgrounds and motels within 5 mi. Contact *Roger W. Dole, RR #2 Box 730, Bangor ME 04401. Tel. (207) 848-3846.*

LOVELAND, CO The Northern Colorado ARC will host "Superfest" 8 AM–3 PM at the Larimer County Fairgrounds, 700 S. Railroad Ave. VE Exams, commercial exhibits, computer and radio goodies, more. Reserve tables from *Jeanene Gage NØYHY, (303) 351-7327. Call Michael Robinson AAØUB at (970) 282-1167* for general info. Talk-in on 145.115(-), 100 Hz.

JUN 2

BUTLER, PA The 42nd Breezeshooters' Hamfest will be held 8 AM–4 PM on the Butler Farm Show grounds, just north of Butler PA. Talk-in on 147.96/.36. Dealers. Hamfest. For more info, call the *Breezeshooters' Hotline at (412) 854-5593.*

PRINCETON, IL The Starved Rock RC Hamfest will be held at Bureau County Fairgrounds beginning at 6 AM. Camping and outdoor Flea Market area is free. Talk-in on 146.355/.955. Contact *Bruce Burton KU9A*, or *Debbie Burton N9DRU. 1153 Union St., Marseilles IL 61341-1710. Tel. (815) 795-2201.*

SPECIAL EVENT STATIONS

MAY 3–5

GAY HEAD, MA The Fall River ARC will conduct their 3rd Annual DX-pedition at the historic Gay Head Cliffs; Martha's Vineyard Island. All HF bands, SSB, CW, 2m FM, 220 FM, 440 FM, and 421.25–439.25 MHz ATV. W1ACT/P will operate on IOTA freq. as NA-046. There will also be a MA QSO Party around 1.810, 1.850, 3.550, 3.890, 7.050, 7.290, 14.270, 21.390, and 28.390 MHz. QSL with SASE to *Roland Daignault, Jr. N1JOY, 19 Davis Rd., Westport MA 02790.*

MAY 4

ALEXANDRIA, VA The Mt. Vernon ARC will operate NJ4F May 4th to commemorate the 133rd Anniversary of the Civil War Battle of Chancellorsville. This will be from the site of "No Man's Land" on the original battlefield. Operation will be in the General portion of the 40 and 20 meter phone bands. CW contacts by request. For certificates, send QSL and large SASE to *MVARC, P.O. Box 7234, Alexandria VA 22307.*

GLEN BURNIE, MD The Bay Area ARS will operate W3QLP 1300 UTC–2000 UTC to commemorate the 152nd Anniversary of the telegraph message "What Hath God Wrought," transmitted on an experimental line from Washington DC to Baltimore MD. CW freqs.: 7.125, 14.125, 21.125 and 28.125 MHz. A 8.5" x 11" commemorative certificate will be offered. Send your QSL card or SWL description of the QSO, along with a large 8.5 x 11 SASE to *Hal Camlin W3QLP, The Bay Area ARS, 7506 Jacqwill Ct., Glen Burnie MD 21061*, for this special award.

MAY 4–5

DANBURY, CT The Connecticut QSO Party, sponsored by the Candlewood ARA, will be held 2000Z May 4th–2000Z May 5th, with a rest period 0400Z–1200Z. Phone, RTTY, and CW. Work stations once per band and mode, mobiles as they cross county lines. No repeater QSOs. Freq.: CW–40 kHz up from lower band edges; Novices 25 kHz up from low end. Phone–1.860, 3.915, 7.280, 14.280, 21.380, 28.380. VHF–50.150, 144.200, 146.580. RTTY–normal RTTY bands (no WARC bands). For more rules and details, contact *CARA, P.O. Box 3441, Danbury CT 06813-3441.*

WALL TOWNSHIP, NJ The Ocean-Monmouth ARC will operate KB2VPQ 1600Z May 4th–1600Z May 5th, to commemorate the Marconi Memorial Tower Site. CW will be up 10 kHz from bottom of Novice subbands, and 10.145, 14.045, 18.080 MHz, the bottom of General 8015, and Novice 10 meter Phone subbands. Send 9" x 12" SASE (or $1 U.S.) to *KB2SEO at his Callbook address*. Visitors welcome.

MAY 9

WEST MIFFLIN, PA The Belle Vernon H.S. ARC will operate KB3BKW from Kennywood Park on Amusement Park Physics Day. Novice 10m, General 15m and 20 meter phone bands. For a certificate, write to *BVAHS ARC, RD 2 Crest Ave., Belle Vernon PA 15012.*

MAY 10–19

HOLLAND, MI The Holland ARC K8DAA will operate to celebrate Tulip Time. Operation will be in the lower portion of the General 20 and 15 mete subbands, 28.400 MHz; and 146.52 simplex, all bands. for a certificate, send QSL with calls worked, and a 9" x 12" SASE to *Barbara Siebelink N8NXA, 6410 Otis Rd., Saugatuck MI 49453.*

MAY 11–12

FLOYD, VA The Foundation for Amateur Internat'l Radio Service will operate KK4WW, US5WE, BY1QH, 8R1WD and S21AM in their own countries to celebrate the 5th Anniversary of FAIRS. General portion of 40, 20, and 15 meters. For a certificate, send QSL and a 9" x 12" SASE to *FAIRS, P.O. Box 341, Floyd VA 24091.*

MAY 17–19

DAYTON, OH The Dayton AR Assn. will celebrate the 1996 Dayton Hamvention by operating W8B1/8 1200 UTC–2100 UTC May 17th; 1200 UTC–2100 UTC May 18th; and 1200 UTC–1600 UTC May 19th. Freq.: 25 kHz up from lower Gen./Nov. PH/CW band edges (op's choice). For a certificate, send SASE to *W8B1/8, P.O. Box 44, Dayton OH 45401-0044.* For more details call *Charlie KA8OQF at (513) 256-3783.*

MAY 18

NEWPORT NEWS, VA The Peninsula ARC will operate W4MT 1500Z–2100Z at the parade site for the Centennial Celebration for the City of Newport News. Operation will be in the General 40, 20, 15m bands, and 145.23(-) Rptr. For a certificate and QSL, send a 9" x 11" SASE to *W4MT, 494 Pamela Dr., Newport News VA 23601.*

MAY 25

ASHTABULA, OH Members of the U.S. Power Squadron's Amateur Radio Net will operate from the Thomas Walters pilot house at The Great Lakes Marine and U.S. Coast Guard Museum from 1400 UTC–2200 UTC. Operations will be in the General portion of the 80, 40, 20 and 15 meter bands, in the Novice portions of 10 meters and on 2 meter simplex. Certificate for a confirming QSL card. Send SASE (for flat certificate send 9" x 12") to *Donald Stark N3HOW, 65 Stark Spur, Eighty Four PA 15330-9633.* 73

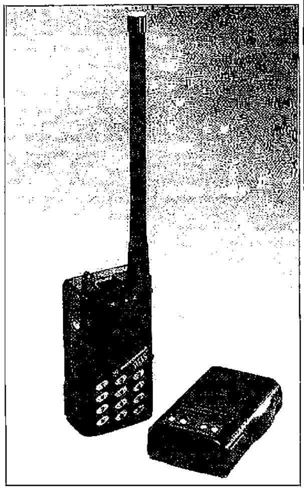
VISAR Replacement Battery and Eliminator



Battery on that HT going dead in the middle of your first QSO after a night on the charger? W & W Associates has announced the addition of the VISAR replacement battery and eliminator to the extensive line of Two-Way batteries. The batteries are available in 7.5V @ 2000mAh and 7.5V @ 1200mAh.

W & W also now stocks batteries for the Yaesu FT-10R/40R, the Icom series IC-W31, IC-21A, IC-T22A, IC-T42A and Alinco DJ190/DJ-G5.

W & W can be reached at (516)942-0011 and is located at 800 South Broadway, Hicksville NY 11801-5017.

The Tee Antenna

Short of room? This antenna may be just your size.

Joseph J. Carr K4IPV
P.O. Box 1099
Falls Church VA 22041

The low frequency bands are a bit of a problem for ham operators and shortwave listeners because longer antennas are required on those bands. For example, while a half wavelength dipole is only about 65 feet long on 40 meters and 126 feet long on 75/80 meters, you need 253 feet on 160 meters. Our SWL friends also have the same problem if they want to use a resonant antenna on the "tropical bands." Note: transmitters are more sensitive to the high VSWR that off-resonance antennas exhibit than receivers.

Real estate ain't getting any cheaper, so buying a 40-acre spread is probably not in most of our futures. *That* solution to the low frequency antenna problem is a non-starter.

One solution to the problem is the Tee-antenna shown in **Fig. 1.** This antenna uses two lengths of 300-ohm twin-lead to make a horizontal section ("A") and a vertical section ("B"). Note that this antenna looks superficially like a folded dipole, but it's: a) only about half as long as a folded dipole, and b) the conductors are continuous, rather than having the feedline drive the antenna in a balanced manner. This antenna is unbalanced.

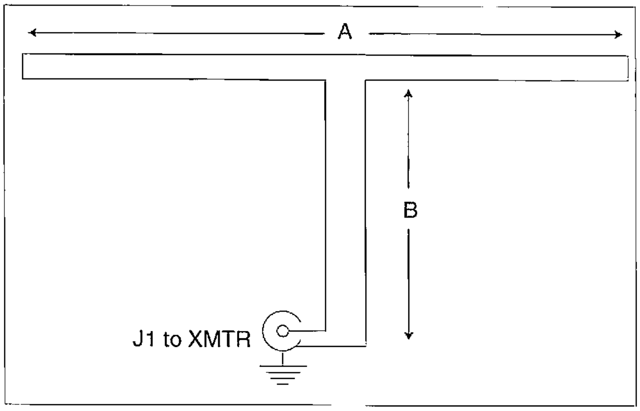

Fig. 1. While it looks *like a folded dipole, it's only about half as long!*

The horizontal section length (in feet) is found from:

$$A_{feet} = 270/F_{MHz} \quad (1)$$

While the vertical section is found from:

$$B_{feet} = 270V/F_{MHz} \quad (2)$$

Where: A and B are the lengths in feet, F_{MHz} is the frequency in megahertz, and V is the velocity factor of the twin-lead transmission line (typically 0.82 for television-antenna-style twin-lead).

Examples of the antenna lengths:

Frequency	A	B
7200 kHz	37.5'	30.75'
3750 kHz	72'	59'
1850 kHz	146'	120'

Win Fame and Fortune!

You can become world famous overnight just by getting an article published in *73*! Have you designed and build something hams would like to know about? Have you put together a kit which really deserves to be better known? Have you had an interesting ham adventure? How about a DXpedition? My answer to any of these questions you answer "no" to is why not? *W2NSD/1*

PROPAGATION

Number 87 on your Feedback card

Jim Gray W1XU
210 Chateau Circle
Payson AZ 85541

May is expected to be a decent DX month on good (G) days, but increasing thunderstorm activity may occasionally frustrate your weak-signal reception on the lower HF bands due to high static (QRN) levels. Expect the poorest (P or VP) conditions between the 5th and the 9th, and again between the 18th and 21st. The best days (G) are anticipated on the 1st and 2nd, 13th-15th, 23rd-25th, and 29th. The remaining days are either fair (F) or trending (F-P, P-F, F-G, and G-F as shown on the calendar).

MAY 1996						
SUN	MON	TUE	WED	THU	FRI	SAT
			1 G	2 G	3 F	4 F-P
5 P	6 P-VP	7 VP-P	8 P-F	9 F-G	10 G-F	11 F
12 F-G	13 G	14 G	15 G	16 G-F	17 F	18 F-P
19 P	20 P	21 P-F	22 F-G	23 G	24 G	25 G
26 G-F	27 F	28 F-G	29 G	30 G-F	31 F-G	

10-12 meters

This is a daylight-only band this month, but may present openings to tropical areas as well as short-skip openings on the best days (G). During intense, sporadic E conditions (rare this month) bursts of strong signals can come and go unexpectedly. Stay alert.

15-17 meters

These bands could stay open into early evening hours with possibilities of trans-equatorial DX on good (G) days and evenings. Signals seem to peak toward the west during afternoon and evening hours. Short-skip to 1,000 miles or so should be available on many days.

20 meters

This should be your main choice for DX-chasing. Because some areas of the world are dark and others are in daylight at the same time, you can expect dawn-to-dusk, and even later, DX opportunities on good (G) days/nights. Short-skip will prevail to about 2,000 during the day, and farther at night.

30-40 meters

You may find these bands quite noisy (QRN) during the daytime, due to the onset of thunderstorms this month, but they will be quieter during the nighttime hours. DX to your east will be the best before midnight, and best to your west before dawn. Choose good (G) days for best chances of scoring a new country. Short-skip of 100-1,000 miles during the day, and 500-2,000 miles or so at night will prevail.

80 meters

You may find that 80 meters will provide DX on good (G) nights, but it will be limited by thunderstorm activity. It may also provide short-skip openings of 200 miles or so during the day and 2,000 miles or more after dark.

160 meters

There will be *no* daytime openings here, due to a high absorption of signals, but it ought to provide skip to 1,000 miles or so after dark. Only rarely will you find DX, and only on good (G) nights with low or no thunderstorm activity. Low-frequency static bursts, hundreds of miles in length, limit your spring and summer operations.

The consensus among the forecasters is that Cycle 22 has reached bottom and will now start slowly upward. It was a short cycle indeed, about 10 years, and that's good news. See you on the bands. W1XU

UPDATES

In the March issue, page 77, column 2 paragraph 2 of "Never Say Die", the telephone number for the SETI project was given as 800-AU-SETI. The correct number is 1-800-TAU-SETI.

In the April issue, page 41, "The Alpha Delta DX-A 160-80-40 Meter Twin Sloper", the author's name was spelled John Stevenson. It is actually spelled John Stephenson.

Oops! In the April issue, page 33, "Alaskan Amateurs and Their Antennas", Photo B , you may have noticed the striking resemblance between Chuck K7JUT/KL7 in Fairbanks and Sarah Anderson W7KZE from page 31, Photo B, "Ham Radio and Summer School". That's because we accidentally printed Sarah's picture twice and left Chuck's out. Apologies all around! Here's the missing picture. Can you recognize Chuck?

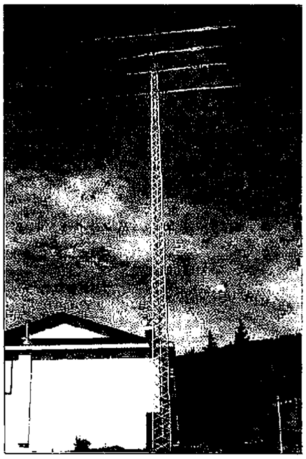

Photo B. Chuck K7JUT/KL7 in Fairbanks.

There are a few corrections in the article, "A Decibel Primer", by Steven R. Sampson, July 1995 issue, page 42. In the 7th paragraph "they need 80 dBm of amplification..." should read, "they need 80 dB of...". In the 8th paragraph also change "the waveguide shows a 1 dBm loss..." to, "the waveguide shows a 1 dB loss..,". Lastly, Mr. Sampson wishes to amend his definition of the word "bel"; "The main definition readers should be aware of, is that 10 dB = 1 bel; therefore, 1dB is 1/10 of a bel. That is, 1 dB is 1/10 of a bel (.1), 6 dB is 6/10 of a bel (.6), and 42 dB is 42/10 of a bel (4.2), etc.."

N2YMW's keyer in "An Inexpensive Morse Code Keyer" ,of the June '95 issue, starting on page 36, had some parts values wrong or left the parts off the list. The schematic, though, is okay.

Here are two equations that should have been part of WA9PYH's "Dish Antenna for Weather Satellite Images" in July 1995's issue: 13. f = D2/16d = 3600/16x8.835 = 25.47"; and 14. Compare to 16.63" + 8.835" = 25.465".

Also in July '95 in WA9PYH's second article, "A Low Noise Amplifier for 1691 MHz" there were errors. In Fig. 5 on page 24, the small holes should be 0.03" and not 0.30" and, in Fig. 6, the "7905 regulator" and all other "7905" should be "7805".

A correction from the Sultanate of Oman pointed out that in May of 1995, the QRX item "Long Walk" on page 8, we implied that Stefan Leca YO8RCW had a Oman license; he did not.

In the July '95 issue, the review "Maldol Antennas HS-2 and HS-75" gave inappropriate designations for the yagis, potentially causing confusion when trying to order either one of them from the dealer. The correct designation for the HS-2 is HSFOX2, and that of the HS-75 is HSFOX75.

The author of the June '95 "Super CW Station", pages 10-16, offered the pre-programmed 87C52 and the PC board for $40, and the convenience pack of all the parts for $85. Some generous readers have been sending $125. What N4UAU meant was that the whole works, including the board and 87C52 are $85, as long as he has parts available. "Stop sending too much money," he cries. Editor's note: if you build this, please keep notes and let us know how much fun you have with it so we can inveigle more readers into having a ball. Share your fun and excitement with a letter to the editor.

HAM HELP

We are happy to provide Ham Help free on a space-available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full 8 1/2" x 11" sheet of paper. Use upper- and lower-case letters where appropriate. Also, print numbers carefully. A 1, for example, can be misread as the letters l, i, or even the number 7. Specifically mention that your message is for the Ham Help Column. Please remember to acknowledge responses to your requests. Thank you for your cooperation.

Due to the Silent Key of W2KF, effective immediately, I have taken over the duties of QSL manager for Pedro Katz, HC1OT - HD1OT - HD9OT. Thanks in advance for your help in this matter. Ed Eklin KG8CY, 810 Harry Paul Dr., Lake Orion MI 48362.

WANTED: LCD display (LP156AE) for my ICOM IC 02AT handy. I also need diode D2 on the CPU initialization matrix. I will gladly pay for both. Thanks. Srikanth VU2GSM, PO Box 5053, Bangalore-560 001, India.

NEVER SAY DIE

Wayne Green W2NSD/1

Elect a Ham

Last month I proposed the first step toward the solution of a lot of our problems; that every ham club in the country make a major effort to get a local ham elected to their state legislature. We desperately need hams in high places to protect us. And not only will a bunch of hams in the state legislatures give us one heck of a louder voice with our states, but also with the Feds.

With the FCC (and Congress) wising up to how much money they can take in selling or leasing the spectrum to commercial users, they're looking for more to sell, and guess which group has the largest hunk of relatively unused microwave frequencies? We either start building some political clout or we'll be blown away.

We need state clout to stop the growing number of antenna-limiting laws and ordinances. But most of all, we need it to get our schools to start teaching electronics, communications and computers. This will get us more hams and help make it so America can compete better in the information age—the 21st century.

I was hoping the Dayton HamVention would allow me give a talk on this, but the ARRL apparently has them under such tight control that this wasn't possible, even considering the importance of the message.

As you read my editorial this month I think you'll see many opportunities where ham legislators could make a difference in education, health care, government, and so on.

If you have any say with the organizers of a hamfest or convention, and they're not totally controlled by the ARRL, maybe you can get me on the speaker's list. I'm not charging anything beyond the costs for Sherry and me being there, which is what any speaker normally gets covered. However, between demands for keynote talks at education, music, and science conferences, my available time is limited.

Your Government at Work

Last year one of those TV shows devoted to the weird did a show interviewing farmers and their children who were involved with that alleged 1947 UFO crash in New Mexico. They sure made a good case for the reality of a crashed UFO and its dead occupants being covered up by the government. It definitely was enough to cause any intelligent person to shake off the bindings of "conventional wisdom" and start looking for more information. Or should that be called "conventional ignorance?"

Of course, having always been interested in the UFO phenomenon, I've done a lot of homework. I've read dozens of books over the last 50 years or so, some very thoroughly researched, others a waste of time. I think I mentioned that back in 1963, Jay Stanton (darn, I forget his call!), a writer friend who was a total UFO skeptic, set off to expose the whole UFO business as bunk. About two years later, no longer a skeptic, his book telling about his conversion was published. He cited some most convincing cases.

I've read enough books, talked with enough people who have had personal experiences, and had enough experiences of my own to know that something real is happening. I also know from several incidents that our beloved government is up to here in a cover-up. Yeah, I know, the old government cover-up baloney.

Well, if I hadn't had a first-hand inside experience with the cover-up in the Amelia Earhart case, which is still being covered up, I might be less easily convinced.

Then, a few days ago, there was another TV weirdo show on the New Mexico UFO crash. This program interviewed the children of some of the Air Force people who were involved. They, like the farmers, had seen the ETs. And their parents, like the farmers, had been threatened by government agents to keep quiet. Or else. Again, their story was most compelling.

But a federal agency wouldn't threaten private citizens, would they? Well, they did *me*. One federal agency got me into a room and explained that if I ever wrote or even published anything about that agency again they would put me in prison and guaranteed I'd never get out. No, I have never written about them again. And I won't, except in my memoirs, where I will have a whole lot of interesting things to write about. But unless you start paying attention to nutrition, the chances are good I'm going to outlive you.

Green's Rocker

A book came a couple days ago from a reader who wanted to swap it for copies of some of my books. This one sure got my attention. I was busy trying to find out more about dowsing from a couple of new books I'd just bought, but this one made me put everything else down.

My first reaction was probably what yours will be. It's *NASA Mooned America!*, by René, 196p, 1994. The ridiculous claim is that the Apollo missions to the moon never actually happened. Oh, Lordy, give me a break! What is this, some Flat Earth Society-type crappola? However, not being completely controlled by what I have been conditioned to believe, I read on. René has done a masterful job of destroying what little faith I had left in NASA. He shows evidence that many of their photographs of the moon missions are clearly bogus; he proves beyond a reasonable doubt that nobody can survive in space beyond the protection of the Van Allen Belt; and so on. By the time he's through, there's just no doubt that our government has produced a $40 billion space opera for us.

Yes, of course, Wayne has gone off his rocker with this one. Sure. Okay, smarty, what's the temperature in space? Hot? Cold? We all know it's awfully cold, right? The fact is, when the sun is shining on anything it gets blistering hot. The surface of the moon is 243°F in the sun and -279°F for the two weeks of night. Our astronauts were just there in the daylight, so they were dealing with an environment that was around 250°, with nowhere near enough power to run the cooling system needed to deal with that. René goes into every aspect of the inability of any living thing to survive the solar flares that occurred during the missions with the little shielding used, the temperatures involved in space and on the moon. The astronauts reported that the LEM blasted a deep crater in landing on the moon. Why has not one NASA photo of the LEM on the moon ever shown a hint of this crater? They do show undisturbed dirt, complete with footprints (more about *that* impossibility later).

There are endless holes in the NASA production. Wait'll you see the not quite hidden power cords in some photos supposedly taken on the moon. Then there's one photo in the book of Aldrin and Armstrong saluting the flag, where they claim the sun is at about 13°, but Aldrin's photo was taken when the sun was at 26.4° and Armstrong's was taken with the sun at 34.9°, if one goes by the shadows they

From the Ham Shack

Matt Paulonis KA2OOX. Uncle Wayne, after being out of ham radio for a number of years, I recently decided to get back into the action. I have to give a special thanks to Bob Chamberlain N2KBC, of the Crystal Radio Club, for his encouragement. I walked into the VE examinations at WECA's hamfest at Yonkers Raceway, intending to sit for a Tech Plus License, but due to Bob's persistence, I walked out with a General! I guess I didn't know all that the knowledge was still up there. My first few hours of returning to amateur radio were looking good. I had yet to run into the type of ham you criticize in your editorials. Later that evening, after borrowing a 2m rig from my friend Ron Masters KO2L, I thought I would get a feel for my newly earned privileges. What better method is there to learn about the local scene than on one of the local repeaters? The radio I was using didn't have PL codes on it, so I was limited to open repeaters. On my drive back into Manhattan from my parents' house on Long Island I tried to reach a couple of repeaters, but could only raise one in Mineola. I announced "KA2OOX/AG listening" a few times on the chance that I could catch someone tuning around. As I was nearing the city limits and about to give up, I finally got a reply. I was excited at first, but then heard what he had to say. I don't remember his call, but he said that he was a part owner of the repeater, and that my announcing myself seven times was absolutely unnecessary. I wondered why, if he had heard me the whole time, and had understood that the ".../AG" at the end of my callsign meant that I was new at this, that he didn't he say, "hello," or something simple like "welcome," or even explain the rules governing "his" repeater. Maybe I was too optimistic to believe that you are wrong and that the majority of hams out there are friendly and willing to help. Now, Wayne, I can say that I can relate to your stories about "closed" or "private" repeaters. So ended my first day as a General. *(That's what I've been running into all around the country! Golly, I'm old enough to remember when amateur radio was considered a fraternity and friendliness was the rule, not the exception. You know, I don't recall seeing one blessed word about this problem in any of the stack of club newsletters I get every month... Wayne.)*

David O'Neil, Greenacres FL. Wayne, you started my publishing career with an article you printed in *Microcomputing* in June of '80. It was about the BASIC physics programs that I use in my class. I had a brandnew shiny SWTPC 6800 computer (kit) loaded with 16K RAM! Well, you let the genie out. I'm on the Internet now, and you are the first person I'm notifying about the address. I also subscribe to *Cold Fusion*, but the high-school engineering-and-science club I sponsor decided we wouldn't try that yet. We have done a one-person dry pedal submarine, ham TV, a TV-eye model car, a TV-eye rocket, a 10-gallon 3-tier beer microbrewery, a 3-axis flight simulation cockpit, and two radio-control lawn mowers. We designed a circuit that uses a TV camera and radio control to keep an R/C car with a light on it going in a straight line automatically. I hope you'll find the time to check us out at: http://www.webeom.com/sknkwrks/ *(Thanks Dave, for the note. I'll bet some of our teacher readers will be checking out your page. Meanwhile tsks and tuts for not getting the club to try a cold fusion project. They could make international fame! And, at this early stage of the game, maybe even get some patents. The world leader, as far as we know, is right over there in Sarasota... Wayne)*

Bill Parker W8DMR. My April article on debunking some myths about antennas, feedlines, and SWR calls for some clarification. Walt Maxwell W2DU has written with regard to vacuum-tube amplifiers, "Whatever the conditions of mismatch at the load end of a transmission line, a matching network properly adjusted to obtain a conjugate match at the line input reflects 100% of the reflected power." No damage occurs to the amplifier. Cecil Moore K67BK wrote to say with regard to solid-state amplifiers, "A reflected voltage wave, due to feeding a long unterminated transmission line, is in phase with the generated voltage." Due to excessive voltage, the solid-state amplifier will fail. Damage will occur. Both Walt and Cecil are correct. A vacuum-tube amplifier with a conjugate match system responds one way; a solid-state fixed 50 ohm output system responds another way. Comparing the two different types of amplifiers should have been included. Yes, even the debunker needs debunking occasionally. See how myths get started? It's easy.

Frank Rumph KD4DZI. Wayne, in the December issue there was an article, "Nostalgia for the Future," which called for 2000 ohm earphones. Since they're hard to find, I solved the problem by putting two 1000 ohm Radio Shack™ output transformers (#273-1380) in series and feeding the two 8 ohm outputs to the low impedance left and right stereo earphones.

NEVER SAY DIE

Continued from page 4

cast. Worse, the shadows are in two different directions, and the flag casts no shadow at all. The angles of the sun were calculated by the lengths of the shadows compared to the height of the men. The sun moves about 10° a day, so Aldrin's photo would have had to be taken a day after they claimed, and Armstrong's a day later, all followed by some computer trickery to combine them.

Or was all of this done in a secret Nevada CIA base?

René provides a book full of proof that the whole moon deal was a fake put together by NASA and the CIA. It's a very well-written and researched book. It reduces our Right Stuff heroes to mere actors who have gone along with a Hollywood-type production. And those who caused any problems were killed! Did the "accidents" which killed 11 astronauts in 1967 raise any questions in your mind?

Illusions

It's difficult for me to get used to the real world. It sure isn't anything like I was taught in school, or anything my parents led me to believe. The more I learn, the less I have to believe in. Politics is crooked clear through, with money, via lobbies, firmly in control. The medical industry is just as crooked, protecting its $1 trillion business with the cooperation of the government. Our legal system is seriously corrupt, as is our educational industry, again with the complicity of the government. Our academic system is corrupt, again in bed with our government. Should I mention our tobacco industry? And liquor industry? Our public water supplies, packed with chlorine and fluorides? Oh yes, our dental industry, with amalgams and root canals. Our food industry, providing us with hormones, pesticides, antibiotics, and de-mineralized produce.

So I suppose I am pretty dumb, or at least naïve, to be surprised to read an exposé showing NASA to be siphoning off billions to produce blockbuster entertainment epics, hand in hand with the CIA.

The worst part is that, even with our government and, as far as I know, every major industry, thoroughly corrupt, we seem to have the best country in the world. Maybe I should just shut up and go along to get along. Maybe I should go back to grumbling about the bad language, rudeness, and endless brain-free contacts on our ham bands. And fan the flames between no-coders and old-timers. The CW and phone ops. And any other ham schisms.

Say, those confounded packeteers aren't going to screw around with the Internet, are they?

Heck, if you get to know many of the ARRL directors beyond the thoroughly whitewashed meeting reports in *QST*, you'll find out in what contempt they hold the members. That really disillusioned me when I got on the inside and got to

QRX . . .

Noteworthy hams

A list of "famous" hams was posted on the Internet. Do you know any famous hams not on this list? Let us know.

7L2NJY Dr. Mamoru Mohri, Japanese astronaut
9K2CS Prince Yousuf Al-Sabah
9N1MM Father Marshall Moran, missionary (SK)
A41AA Qaboos Bin Said Al-Said, Sultan of Oman
EAØJC Juan Carlos, King of Spain
FO5GJ Marlon Brando AKA Martin Brandeaux, actor
G2DQU Lord Rix (formerly Sir Brian), former actor and charity head
G3TZH Tony Dolby, brother of "the" Dolby
G3YLA Jim Bacon OBE, weatherman
GB1MIR Helen Sharman, astronaut
HS1A Bhumlphol Adulayadej, King of Thailand
I0FCG Francesco Cossiga, former President of Italy
JA5FHB Japanese Minister for Transport and Communications
JY1 King Hussein of Jordan
JY2 Queen Noor of Jordan
K0HWY Tex Beneke, band leader
K1OKI Mickey Schulhof, head of Sony US
K2HEP John Sculley, CEO of Apple (lapsed)
K2ORS Jean Shepard, author
K4LIB Arthur Godfrey, TV performer (SK)
K6DUE Roy Neal, television reporter
K7TA Clifford Stoll, author & scientist
K7UGA Senator (US) Barry Goldwater
KB2GSD Walter Cronkite, news reader
KB6LQR Jeana Yeager, Voyager '86 pilot
KB6LQS Dick Rutan, Voyager '86 pilot
KB6OLJ Paul J Cohen, mathematician
KC4OCA Gordon Barnes, weatherman
KD6OY Garry Shandling, comedian
KG7JF Jeff Duntemann, author
LU1SM Carlos Saul Menem, President of Argentina
N4KET David French, CNN newsman
N4RH Ralph Haller, FCC PRB chief
N5YYV Kathy Sullivan, Chief Scientist NOAA (former astronaut)
N6FUP Stu Cook, baseball player
NK7U Joe Rudi, baseball player
ON1AFD Count Dirk Frimouth, Belgian astronaut
S21A Head of Bangladeshi PTT
SU1VN/P Prince Talal of Saudi Arabia
SV2ASP/A Monk Apollo
U2MIR/UV3AM Musa Manarov, cosmonaut
VK2BL Graham Connelly, radio announcer
VK2DIK Dick Smith, entrepreneur & millionaire
VK2KB Sir Allan Fairhall, politician
VK2YOW Bob Hughes, radio announcer
VU2RG Rajiv Gandhi, Prime Minister of India (SK)
VU2SON Sonia Gandhi, XYL of VU2RG
WOORE Tony England, astronaut
W3ACE Armin Meyer, US Ambassador to Japan
W4ZG Worth Gruelle, started Raggedy Ann and Andy
W5LFL Owen Garriot, astronaut
W6EZV General Curtis LeMay (SK)
W6FZZ Samuel F.B. Morse III
W6JKV James Treybig, CEO of Tandem
W6QHS President of California Microware
W6QYI Cardinal Roger Mahony
W8JK John Kraus, astronomer
WA4CZD Chet Atkins, guitar player
WA4SIR Ron Parise, astronaut
WA6TJM President of ISD Inc.
WA7WYV Andy Griffith, actor
WB4KCG Ronnie Milsap, singer
WB6ACU Joe Walsh, singer
WB6RER Andy Devine, actor (SK)
WD4SKT Donny Osmond, entertainer
KD4WUJ Patty Loveless, singer
WP4CO Jose Feliciano, singer

New Zealand forcing CW to be dropped internationally?

At the last ITU WRC meeting (1995) an initiative was opened by the NZ delegation to visit this issue. The agenda Item was not pursued at that meeting, but will appear as part of a larger "look" at amateur radio at the 1999 WRC.

Many national societies are now examining this issue, including ARRL, RSGB, RAC, IARU, etc. IARU and ARRL have established working groups to prepare for WRC-99. You should contact your national society with your views and recommendations as early as possible.

Agenda item "2.2 Consideration of Article S25 concerning the amateur and amateur satellite services" for WRC-99.(Art. S25 renumbers previous Art. S32 which contained Radio Reg. 2375, amateur Morse tests for HF privileges internationally.) As result, the IARU has established a committee called The Future of the Amateur Service Committee (FASC) to assist/ advise the IARU in formulating policy/positions on the above WRC-99 agenda item.

The committee has a long list of matters on the agenda, and the committee is to encourage full discussion of these matters; invite comments from individuals, groups, member societies, and regional organizations; participate in meetings and take into account comments it receives; prepare reports, recommendations, and proposals by the Administrative Council, member societies and others.

As a first step, all IARU member societies have been invited to send opinions to the chairman of the FASC (VK3KI) as to "how the Radio Regulations might be modified or improved to meet the challenges of the 21st Century".

The first regional conference to consider recommendations from the committee will be the Region 1 Conference to be held in Israel, September 1996. Others will be held over the following two years leading to WRC-99.

In the UK, the Radiocommunications Agency has asked the Radio Society of Great Britain to consider formally the proposal to delete Morse testing as a requirement for HF privilege. "Whether the Morse test is a relevant means of differentiation (between classes of license)...It is clear that this is an issue on which there are differing and strongly held opinions. It is now timely to reconsider this issue and to decide whether the Morse requirement is one in which radio amateurs see relevance to the next millenium."

In France, F6IIE, vice-president of UFT (Union Francaise des Telegraphiste) has written, "Let those who are against the CW exam not delude themselves, they risk having something other than CW to learn. Those who are in trusteeship will not do away with (overnight) a 'filter' so efficient for controlling access lo the HF bands...the CW examination is not really so difficult...it opens up horizons certainly more interesting than all the data-processing systems (which are) useful indeed, but of which one tires so quickly, and which render communications more and more impersonal." (Translated from *La Pioche*, journal of UTF, by Ken Quigg GI4CRQ, and printed in *Morsum Magnificat*, Feb. '96.)

This will be a hot topic in the two and a half years before WRC-99. Be prepared to respond to surveys/ polls by ARRL and probably others, and to clearly express your reasons for retaining or dropping Morse as a requirement for HF operating privileges. Obviously the English and French are moving out smartly to face the issue, and do have opinions already in mind!

We are only a few months away from the first meeting at which the issue will be formally discussed in light of the WRC-99 agenda, so you might want to organize some thoughts carefully on the issue and maybe E-mail or post to the FASC committee member of your country, or nearest you.de AH6NB

Hams get help from Baker

Rep. Bill Baker (R-California) has introduced a bill to protect ham volunteers in the Volunteer Examination program and the Amateur Auxiliary of the FCC from frivolous lawsuits while they are doing their volunteer jobs. The bill, HR 3207, would afford amateurs engaged in statutorily defined activities with the VE program and with the Amateur Auxiliary the same liability as federal workers under the Federal Tort Claims Act. When individuals who fall under such protection are sued for something they have done while performing their duties, the Federal government steps in to protect them. Baker introduced the measure, the Amateur Radio Volunteer Services Act of 1996, March 29, 1996, as an amendment to the Communications Act. While the bill would not afford absolute blanket immunity, it does offer a fairly rigorous body of legal protection from the kind of malicious litigation that tends to frighten volunteers away from these activities, said ARRL Legislative and Public Affairs Manager Steve Mansfield, N1MZA.

Baker said that Amateur Radio volunteers provide an invaluable service to all ham radio operators by assisting in licensing and monitoring activities, thus saving taxpayer dollars. Those savings would dry up if volunteers stay away for fear of lawsuits, Baker said in a letter to colleagues. The bill is a simplified version of legislation originally introduced in the 103rd Congress by Rep. Jim Slattery. Individuals and private organizations currently protected by the Federal Tort Claims Act include Volunteers in Service to America (VISTA), the Peace Corps and the Job Corps.

Baker has enlisted members of both parties as original cosponsors of the bill. These include: Charles Wilson (D-TX); Bob Wise (D-WV); Edolphus Townes (D-NY); Mike Parker (R-MS); Toby Roth (R-WI); Charles Taylor (R-NC); Ron Dellums (D-CA); David Funderburk, K4TPJ, (R-NC); Ed Royce (R-CA); Norman Dicks (D-WA); Vern Ehlers (R-MI); Chris Cox (R-CA); Andrew Jacobs (D-IN); Harold Rogers (R-KY); Dennis Hastert (R-IL); Dave Weldon (R-FL); Anna Eshoo (D-CA); Ken Calvert (R-CA); Doug Bereuter (R-NE); Gene Green (D-TX); George E. Brown (D-CA); Eva Clayton (D-NC); and Sam Farr (D-CA).

Hams may want to write their own Congressional

Representatives urging them to support HR 3207. (From: *ARRL Bulletin* 19, 4/96.)

Harrisburg, PA, hams help in floods

About thirty volunteers from a Pennsylvania radio club came to the aid of the Red Cross to help after the Susquehanna River overflowed its banks, flooding the state capital on January 20th. According to John Obradovich W3IS, President of the Harrisburg Radio Amateur Club, hams provided communication between Dauphin County Red Cross headquarters and two mass-care facilities that lacked telephone service. The following day, the Red Cross requested additional volunteers with vehicles for disaster assessment training and reporting. Several hams were among those who reported.

No electronic renewal

The FCC will not renew your license electronically. So says the ARRL's Regulatory Information Branch in response to several recent queries. The League says that you can now download Form 610 from the FCC fax-on-demand service or from the FCC's home page on the World Wide Web.

The FCC now only renews a ham radio license if an application is received within 90 days before or two years after the expiration date. It will not be renewed if submitted earlier. And, if you apply for renewal after your license has expired, you may not operate until the application has been processed.

As announced last year, there is really no good reason for a person not to renew his or her license prior to expiration. Since last fall, the FCC has been sending out a mail-in reminder called Form 610-R. You should receive it at least 90 days before your ticket expires. If all of the information is correct, you just need to sign the form and return it. If for some reason you do not get a Form 610-R, a regular Form 610 is OK to use. From AMATEUR RADIO NEWSLINE

NEVER SAY DIE

Continued from page 6

know all the players. Suddenly I found that the ARRL General Manager, the League counsel, and the directors all thought of the members as sheep, with no opinions worthy of consideration. It's the same arrogant attitude I see in most politicians.

Hey, if I suddenly "die" of a heart attack, I want you to know that my heart is in fine shape and that the CIA seems to leave a trail of heart attack victims who have caused trouble. Shades of the KGB! The Apollo mission data is still highly classified, so my reporting on the book may be endangering our country.

Exit Line

When this book arrived and I saw that it was an exposé of NASA, claiming that the moon flights were all faked, I expected to start reading the usual unsupported baloney like that which supports just about every claim I've read for zero-point energy, N-machines, and other mysterious new power sources. I was a 100% total believer in space flight. Oh, I didn't think the potential benefits of visiting Mars were worth the investment, considering the federal deficit, so I was glad to see that program canceled last year. Ditto the super collider.

But I've been a space fan since childhood. I got hooked early by a cartoon strip around 1929 called "Jack Swift." No relation to Tom Swift, though later in my childhood I enjoyed those books. Buck Rogers was there, but he didn't hold a candle to Jack Swift. Nor did Flash Gordon. Heck, the early Buck Rogers cartoons still had people using airplanes in the 25th century. Tsk.

So the whole idea that the Apollo flights had been no more real than the recent

The Discharger

A NiCd nurse you really should build.

Marion D. Kitchens K4GOK
2709 Colt Run Road
Oakton VA 22124-1101

A battery *discharger*? Why would you want to discharge batteries? There are two reasons for discharging your NiCds. One is to measure the capacity of the battery pack to determine if it has exceeded its useful life. We all know that even NiCds have a finite life span, but we tend to assume they are good forever in everyday practice. Many NiCds are, however, rated for about 1,000 discharge-recharge cycles.

The other reason for discharging your NiCds is to recycle them to recover from "low energy memory." If NiCds are only partially discharged and then recharged repeatedly, they tend to "remember" this limited duty cycle and will not thereafter deliver their full rated capacity. They can often be recovered by a series of controlled discharges and recharges.

The Discharger was intended to help 4 to 12 NiCd cells, and allows measurement of the energy capacity of the pack. It can be used to determine when batteries are no longer useful, and as a test device to measure the useful life of a variety of different battery types. Knowing a battery pack's useful life or capacity can be a lifesaver in situations where battery discharge can result in damage or loss, such as in radio-controlled model airplanes. When used in recycling batteries, the Discharger will provide a measure of capacity for each discharge-recharge cycle to let the user determine whether or not progress is being made. The Discharger will automatically measure the time to discharge a battery pack so you can read it later at your convenience, thus eliminating the need to monitor the process in real time.

The Discharger is simple to build and to use. There are no critical adjustments or fussy circuits. All parts are readily available from a variety of sources. I have included a PCB layout, a Parts List, and parts placement drawings. Etched and drilled PCBs are available from FAR Circuits (18N 640 Field Court, Dundee IL 60118), or you can make your own. LED indicators show the state of circuit operation. You simply build it and use it, after checkout of course. Data measured on batteries at this QTH are provided for comparison with your batteries.

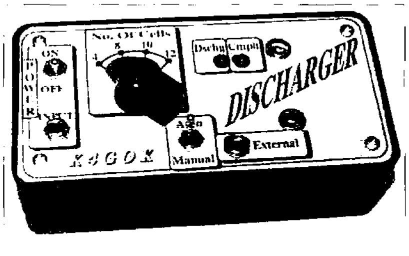

***Photo A.** The completed discharger (prototype unit).*

I you enjoy building and using simple "hassle savers," you will want to build the Discharger. It's a handy test device to have around your ham shack.

Theory

The purpose of the Discharger is to discharge your battery pack at a known current rate (200 mA in the design), and measure the time it takes to discharge the batteries. The time-current product is then a measure of your battery pack capacity in mA-hr. Discharge is to a voltage of 1.0 volts per cell in the pack. The Discharger circuit compares the battery pack voltage to a known voltage, and when the voltage is 1.0 volts per cell in the pack, the Discharger switches to an idle current (12-15 mA) and thereby terminates the discharge.

Fig. 1 shows a functional block diagram of the Discharger. The circuit is powered from the battery pack being discharged. A multi-position switch provides a voltage tap-off from the battery pack to the comparators, dependent on the number of cells in your battery pack. That voltage is compared to a stable 2.5

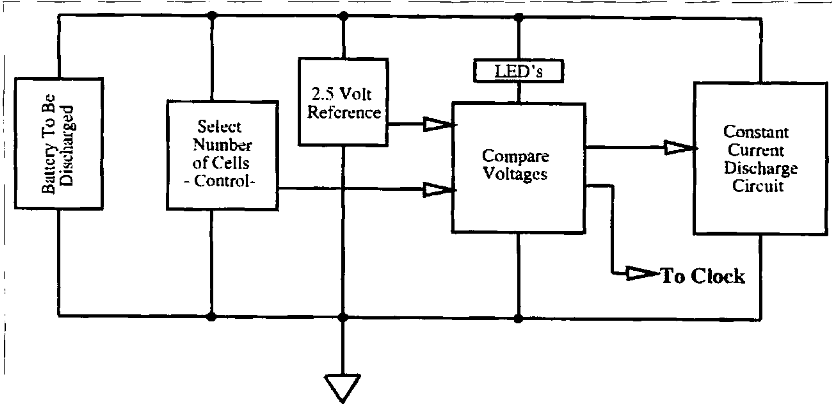

***Fig. 1.** Discharger block diagram.*

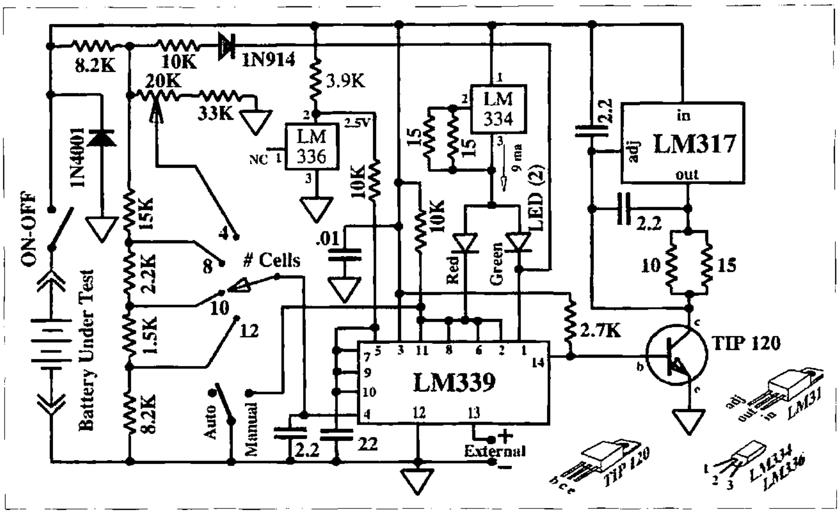

Fig. 2. Discharger schematic.

volt reference. As long as the voltage on each of the cells in your battery pack remains above 1.0 volts, the constant current discharge circuit is activated, as are the appropriate LED indicators.

Discharging to less than 1.0 volts is not recommended. For example, on a four-cell pack, the voltage would be 4.0 volts when the discharge is completed. When the battery pack voltage falls below 1.0 volts per cell, the discharge circuit is disabled and the circuit goes into an idle mode. To measure the discharge time, an external clock is also active as long as the discharge circuit is.

The discharge current of the Discharger is set at 200 mA, so a 400 mA-hr. battery pack should discharge in about two hours if it is at rated capacity. The external clock should then measure a discharge time of around two hours.

The complete schematic is shown in **Fig. 2.** A resistor divider string allows selection of the number of cells in your battery pack, thus providing a suitable voltage to the LM339 comparator. An LM336 2.5 volt reference provides the other input to the LM339 comparator. The remaining comparators of the LM339 are used as logic elements to operate the LEDs, the External control (clock), and the LM317 constant current part of the circuit. Note that the LM339 enables/disables the LM317 circuit by controlling the series TIP-120 transistor. The LM334 provides a constant current of about 9 mA for the LEDs, to prevent burnout with the wide range of voltages over which they have to operate.

Note that the 10k resistor in series with the 1N914 diode connected to pin 1 of the LM339 provides hysteresis to prevent the discharge circuit from re-energizing once the discharge cycle is completed. The Auto/Manual switch forces the LM339 logic into the discharge mode when in the Manual position, which is useful in certain situations, but not normally used. The 1N4001 diode across the battery input prevents reverse polarity from being applied to the circuit. An in-line fuse should be used so it will blow if the battery connections are accidentally reversed.

The only comparator actually being used as a simple comparator is the one with inputs on pins 4 and 5, and output at pin 2. The other comparators in the LM339 chip are being used as logic gates to control the rest of the circuit. The red LED is on as long as the battery pack is being discharged. It switches off and the green LED comes on when the discharge is complete.

Construction

The construction is rather straightforward using the PCB. The PCB foil pattern is shown in **Fig. 3**. Check out each portion of the circuit as it is constructed. The unit is designed to fit a 5-1/16" long, 2-5/8" wide, 1-5/8" deep experimenter box with a metal closure. Note that the usual thin sheet metal closure that comes with the experimenter box does not provide an adequate heat sink and should be replaced with a panel at least 1/16" thick. **Fig. 4** shows the drill pattern for the enclosure.

Study the schematic (**Fig. 2**) and the parts placement drawing (**Fig. 5**) before starting construction.

First, put in all the resistors, caps and diodes. Install the LM336 and LM334, and tack solder the LEDs in place. Check to make sure these are all installed with proper polarity; it's easy to install the LEDs wrong. The anodes of the LEDs should be connected to the two 15Ω resistors. Do not install the LM317, TIP-120 or LM339 yet. Use an in-line fuse of about 1 amp, and apply 5 VDC to the board. The fuse will blow if you connect the power with reverse polarity—that's what it's for. On 5 VDC, the current should be only about 1 mA. Check for proper voltages on the IC socket. Only pin 12 should be connected to ground. Pins 5, 7, 9, and 10 should be at 2.5 volts, and pins 2, 3, 6, 8, 11, and 14 should be at 5.0 volts.

Next, jump pin 2 to ground, and the red LED should light up. Jump pin 1 to ground and the green LED should come

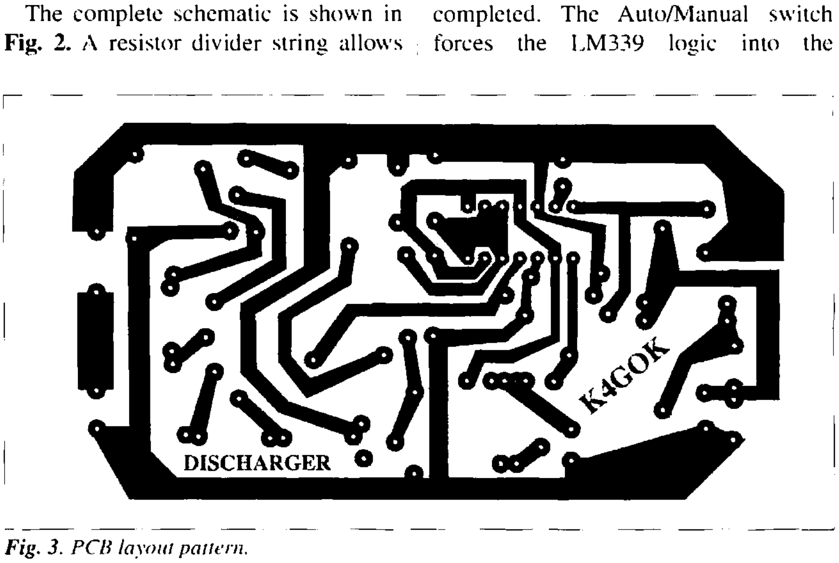

Fig. 3. PCB layout pattern.

NEVER SAY DIE

Continued from page 9

award-winning Apollo-13 movie was totally preposterous. But once I started reading I couldn't stop. Indisputable evidence piled up, fact after fact. As far as I know, no one who has read the book remains unconvinced that the world has been sucked in by one of the biggest snow jobs in history. If you read the book and aren't amazed at the enormousness of the deceit, and the success NASA and the CIA have had in keeping it secret, I sure want to hear from you.

Well, they did as good a job with secrecy on the Manhattan Project back 50-some years ago, so it's not without precedent.

And why didn't Russia blow the whistle, when they had to know early on that man would never survive in space beyond the Van Allen Belt without massive shielding against the intense radiation from solar flares? Read the book on our cost to bribe them.

Say, I wonder what else our beloved government has been doing that we haven't heard about? Let me know, okay?

Radio Bookshop

I've been going out of my way to avoid selling the books I've been recommending, knowing that some money-oriented readers would cry that I was "just trying to sell books." On the other hand, some of the books I've recommended are difficult to find, so I'll start adding some of them to the Radio Bookshop inventory. The Bookshop, which I started in 1958, has always been just a service, and never organized for a profit.

Anyway, if you're interested in having something really interesting to talk about on the air, I've arranged for Radio Bookshop to handle the NASA book. I don't think you're going to find it in any book stores. Send $25 plus $5 shipping/handling to Radio Bookshop, 70 North 202, Peterborough NH 03458. If you order any other books (like mine, for instance), the one shipping charge covers everything. Foreign orders will have to be more to cover the shipping. (See order form page 88.)

Instinct?

Now what in heck is instinct? European cuckoos, which are raised by birds of other species, migrate without guidance to precisely the spot in Africa where their parents migrated before them. Fish return to the streams where they hatched to spawn. Turtles find the exact same beaches where they were born. Monarch butterflies make one migration, from the Great Lakes region to specific butterfly trees in Mexico. The examples that "science" explains as instinct are endless. So, what's instinct?

What science can't explain it gives a name to and ignores or denies.

How do lost animals find their owners in places they've never been before? When a rat learns to navigate a maze, how can future unrelated generations be born with the knack for similar mazes? Is there a whole lot more to the adaptation of species than random Darwinian survival of the fittest?

If you decide to do some research along these lines you'll find organized science fighting you every inch of the way with ridicule, a refusal to publish your papers, and efforts to prevent any funding. Is it any wonder that our progress in non-accepted scientific fields has been so slow?

In the US I've seen the efforts of the Department of Energy scientists to make absolutely sure that if a new cold fusion industry develops, it will be in Japan, not here in America.

According to *The Skeptical Inquirer*, telepathy doesn't exist, yet almost every day I experience it with Sherry. She'll be driving along, with me in the back seat working, and I'll suddenly look up and remark on a sign or something unusual. Every time, it's something she's particularly noted and wanted to tell me about, but didn't want to interrupt my work.

I've reviewed books for you on how to communicate with plants and animals. Science is doing well with microcircuit development, but sure has a long way to go (with other scientists fighting every inch of the way) toward understanding psi, instinct, and other such phenomenon it doesn't understand and thus ignores or denies.

The comforting thought is that virtually every scientific belief (law) is eventually shown to be either untrue, or just partly true.

Continued on page 15

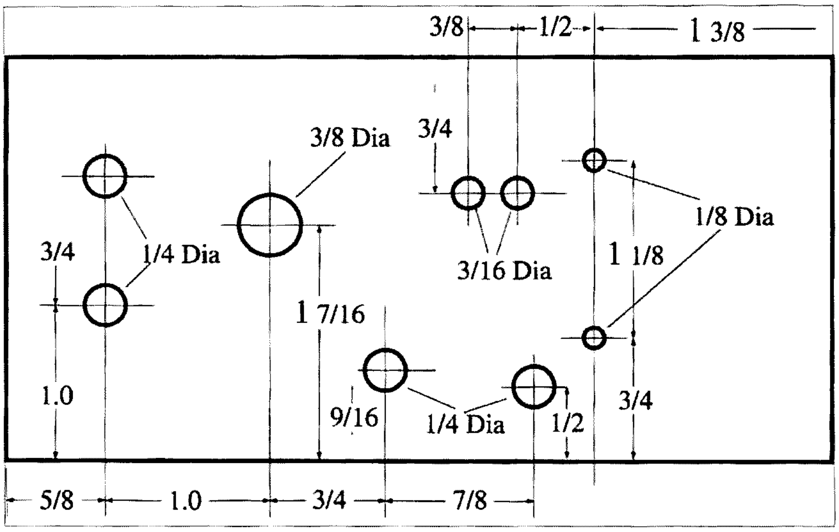

Fig. 4. Drill hole pattern for a 5" x 2.5" panel.

on. Connect the "Manual" (Auto/Manual switch) copper land to ground and the red LED should light up again. Remove the 5 VDC power before installing the LM339 in its socket, and check for proper orientation. Simulate the #4 Cell switch position by temporarily connecting pin 4 of the LM339 to the wiper of the 20k pot. Apply 5 VDC to the unit and the green light should flash briefly before the red light comes on. Current consumption should be 10 to 12 mA with the red LED on. Adjust the 20k pot for 3.08 volts on pin 4 of the LM339. You may want to refine this adjustment later. The control switches, LM317 and TIP-120, should be mounted next.

See **Fig. 6**, **Fig. 7**, and **Photo C** for the suggested method of doing this.

Note the orientation of the rotary switch, making sure the solder lugs are aligned with the PCB solder holes. Only four "positions" and the "pole" of the rotary switch are used. The switches and jacks should be mounted on the sheet metal closure, and short solid wires soldered to the pins as shown. The LM317 and TIP-120 should be mounted to the angle aluminum with insulators, as shown in the drawings. Be sure to use thermal compound when mounting the LM317 to the aluminum angle.

Next, bolt the aluminum angle to the closure, using thermal compound between the aluminum angle and the 1/16" thick closure. The assembled PCB should then be positioned over the solid wires and the LM317 and TIP-120 leads. Note that the circuit components are oriented toward the switches and closure. Make sure the ground lugs of the two jacks are connected to circuit ground, and the other lugs are connected to the positive battery input and to the output of the LM339 chip (pin 13). An error here will cause a short circuit!

Push the assembled PCB down until it is about 1 inch above the front metal panel (closure). Make sure it is square with the metal panel before soldering the connections. It is a bit of a chore to get all the wires in place, but be patient—the result is worth the effort. Now solder all the wire leads to the circuit board. You might want to adjust the length of the LED leads at this point for proper protrusion through the closure. **Photo D** shows the resulting components all mounted on the circuit board. The closure serves as the Discharger front panel (see **Photo E**). If you are not following the suggested construction technique, be sure to mount the LM317 on a suitable heat sink, and insulate it from ground. The TIP-120 needs to be insulated too, but since no heat-sinking is required it can be left free-standing on the PCB. **Photo F** shows WØDLQ's standard construction technique.

Continue the checkout as shown in the **Discharge Checkout Sequence** sidebar, using a variable voltage power supply to simulate the discharging battery pack. The supply should be rated at more than 200 mA, and capable of controlling the voltage to the indicated values accurately and easily. Conduct these tests in the sequence shown; otherwise the results can be confusing. When conducting the tests listed in this sidebar, you will note that the supply voltages for the switch between the red and green LEDs is different when the voltage is decreasing than when the voltage is increasing. That is because of the built-in hysteresis. It is the decreasing trip points that need to be accurate. That's what's happening as a battery is being discharged, of course, and that is what this circuit is for—discharging batteries.

As a final check, you could verify that the External connection goes to ground when the red LED is on. An LED with a current-limiting resistor makes a good indicator for that. Make sure the positive input goes to pin 13 of the LM339 chip, and ground goes to the Discharger ground. Limit the current into pin 13 to about 12-15 mA. The LM317 should not get hot on a 4 or 5 volt supply. You might want to check its temperature on higher battery voltages to verify that your heat sink is adequate.

Epileptic Fits

Thank heavens for the fast-forward on my VCR remote! Well, with exposé TV programs on almost every night, there's always the chance that if I don't record them I'll miss finding out about another military-industrial complex boondoggle, another Congressional, medical, food stamp, welfare, and so on scam. The fast-forward button helps me avoid not only the commercials, but the wallowing in others' misfortunes, which the networks squeeze for every teardrop on these shows.

Did you catch the "Dateline" program with the exposé on the medical scandal over epilepsy? Any time you think that old Uncle Wayne is exaggerating about the mendacity of our so-called health care servers, who fight every low cost cure for a serious illness ferociously, all you have to do is a little reading. Like the *Racketeering In Medicine* book, which I recommended moons ago. Yes, it's on my list of books you're crazy if you don't read.

The program explained that around 70 years ago a very successful cure was found for epilepsy. But since it did not call for the use of any pharmaceuticals, the medical industry buried it. Except for one woman, who fought the medical bureaucracy for years, this cure would have been lost. Now kids with epilepsy can get this dietary treatment at Johns Hopkins, but only if they learn about it. Unfortunately, the AMA-FDA-NIH-WHO cartel has done a magnificent job of keeping most doctors unaware of this simple cure.

Maybe you saw the program about the Australian doctor who discovered an inexpensive quick cure for ulcers. The medical establishment fought him tooth and bloody nail for years before he finally won. I think it was the article about him in *The New Yorker* which finally blew off the lid. The medical journals, which play only the pharmaceutical company tunes, refused to publish his papers.

Let's Play Doctor

There's a new book (well, new to me) that'll be on the next expansion of my list of

recommended books. This is *Let's Play Doctor*, by Dr. Joel Wallach. He's the Nobel Laureate nominee who started out as a vet for around 17 years and then, as he puts it, got his license to kill, his MD.

I got introduced to Wallach by three different readers, who sent me tapes of a talk he gave called "Dead Doctors Don't Lie." I should put the tape on my book list; it's spectacularly interesting. So I sent for his book. Wow! I find I'm using it almost every day for reference. It's a large format book, 203p, 1995, $13 from Wellness Lifestyle, Box 1222, Bonita CA 91908.

Wallach points out that most of the illnesses from which people suffer also used to afflict animals and thus be costly to farmers. Simple, inexpensive cures for these illnesses were discovered years ago by veterinarians. Today, animals no longer suffer from arthritis, Alzheimer's, diabetes, heart trouble, and so on. Just the victims of our "health care" industry. Sorry, but the more I learn, the less I trust doctors, lawyers, politicians, and the chairmen of other major industries. Oh yes, and any government bureau...except, of course, the FCC.

The question arises...are you and all of your family in top-notch, fit and trim, robust health? If not, are you interested enough to learn more about your problems and maybe solve them? Probably not, if it means having to read some books. Right?

Healthy, Wealthy & Wise

How does that resonate with you? Well, in addition to my occasional grumbles about how we can make amateur radio more fun, I've been thinking and

Continued on page 17

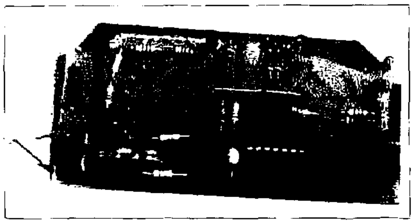

Photo B. Completed PCB assembly, without switches, etc.

Use a battery-operated mechanical clock so that it retains the display after power is turned off. The Discharger turns the clock power on when the battery pack is being discharged, and off when it is finished. Set the clock to 12:00 at the start of a run so that it will display the exact discharge time when the run ends. The connection at the External is an open collector NPN transistor inside the LM339. It can be used to operate a variety of things other than the clock, if desired. The transistor is rated at 15 mA and 35 V. **Photo G** shows the Discharger, battery, and clock ready for operation.

Operation

Connect your clock with its battery wire through the External jack as indicated in **Fig. 8.** Set the Auto/Manual switch to the Auto position, and the No. of Cells switch to the number of cells in your battery pack. For example, if your battery pack contains four cells, set the switch to position 4. Be sure to use a 1 amp fuse in the line between your battery and the Discharger, and plug your battery into the Input jack. Turn on the power switch, and check that the clock is running. Reversed polarity connections between the clock and the Discharger will cause the LEDs to blink on and off—make sure the polarity is correct and the clock is running. When the discharge is complete the red LED will go off, the green LED will come on, and the clock will stop. Record the time on the clock after discharge is completed. Multiply that by 200 mA and you will have the mA-hr capacity of the battery pack just tested. For example, if the clock reads one hour and 45 minutes, your battery pack has 350 mA-hr capacity.

To get a more precise measurement, you can measure the discharge current by putting a mA meter in the power leads when initiating the discharge—you should have recorded this value during checkout. This value will change very little as the battery is being discharged, and is reasonably independent of the battery pack voltage; therefore, it can be measured only once, and then that value can be used for all battery pack discharges.

To determine if your battery pack has exceeded its useful life, you will want to put it through several charge/discharge cycles. Start with a fully charged battery pack, and measure its discharge time. Make sure that the mA-hr measured is near the rated capacity of your battery pack. If it is, simply recharge the pack and put it to use. If the measured mA-hr capacity is not near the rated capacity, you will want to "recover" the battery pack. To do that, repeat the discharge/recharge cycle several times. After three charge/discharge cycles, the battery pack should show increased mA-hr capacity if it is still useful. Repeat the charge discharge process until the battery pack no longer increases its mA-hr capacity. Doing this a few times will make the user appreciate the Auto feature of the Discharger, because you don't have to monitor the process—just read the clock when it is convenient.

Proper operation of the Discharger assumes that all cells in the battery pack are good. A shorted cell will cause improper voltages and improper operation of the unit. You will normally want to start with a fully charged battery pack. Note that the Discharger will not operate properly on battery pack voltages below about 3.5 volts.

During normal operation the Auto/Manual switch should be in the Auto position. That allows the internal circuit to determine when the voltage on each cell in the battery pack has reached 1.0 volts, and shut down the 200 mA discharge current. If your battery pack has a number of cells not selectable from the No. of Cells switch, then you can use the Manual operating mode. In this mode, the discharge circuits are forced into 200 mA discharge current operation, independently of the battery pack voltage. Therefore, the operator will have to monitor the battery voltage manually to determine when the battery pack is discharged. Discharge of battery packs with more than 12 cells is not recommended because of the thermal load they impose on the LM317. The red and green LED indicators tell the operator what discharge mode the circuit is operating in. When the red LED is on, the battery pack is being discharged at 200 mA. When the green LED is on, the discharge is completed and the current has been reduced to about 10 mA.

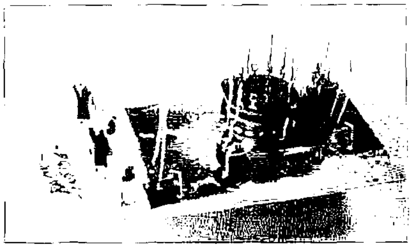

Photo C. Leads on switches, ready for PCB attachment.

Measured results

The results of measuring the capacity of a number of NiCd battery packs are shown in the **Battery Discharge Data** sidebar. Note the sometimes small, but notable, improvements achieved by the discharge/recharge cycling. Some battery packs (not shown in the charts) were found with quite weak cells and showed marked improvements via the cycling process. For comparison, the chart shows the mA-hr capacity measured for a fresh set of Alkaline AA cells.

Acknowledgment

The contributions of Gene WØDLQ played an important part in the design and refinement of the Discharger circuit.

NEVER SAY DIE
Continued from page 15

writing a good deal about the HW&W aspects of life...much to the annoyance of monomaniacal hams. But the listener response to my appearance on the Art Bell (W6OBB) radio talk show was almost enough to get me thinking.

It was a three-hour interview and Art sells the tapes, if you're interested. It originally was broadcast on November 17th, and then rebroadcast on January 1. I talked a lot about amateur radio (of course) and a bunch of other things.

While my enthusiasm for amateur radio brought a few inquiries for more information, my discussion of health was the one that resonated the most and resulted in something over 2,000 letters. If you got a response like that to an interview it might almost make you think too.

Let me sum up my message. If you're interested in being healthy, wealthy, and wise, you have to start first with wisdom. And that means reading. If you read the right books you'll be healthy and wealthy. I'm convinced that you can, by making some nutritional changes, double your normal life span. And by knowing the well-kept secret to wealth, you can become a millionaire in five to seven years, starting from scratch.

The catch is simple. It's *change*, and most people would rather die (and will) than change their habits.

Health

Let me put this simply. After reading a lot and talking with some people I trust as experts, I'm convinced that when it comes to long-term illnesses, they're *all* the result of poor eating habits. And most, if not all, can be reversed by changing your diet. If you eat right and add the minerals and vitamins that are long gone from our industrially truck-farmed land, you're not going to have diabetes, arthritis, Alzheimer's, Parkinson's, heart attacks, brittle bones as you age, and so on. Worse, you can raise holy hell with the Social Security system by living to 120-150 years in good robust health.

I won't go into the details of what foods and additives you need in your diet, but I have a pretty good idea, and it includes changing your drinking water to eliminate chlorine and fluorides, as well as very small, but pervasive amounts of new chemicals. Maybe you read the article in the January 15th ('96) *The New Yorker* on the plummeting sperm count worldwide. I've been recommending this magazine for a long time for anyone interested in developing wisdom. Hey, you aren't born wise, you have to work diligently to build wisdom. The Good Lord wipes the RAM slate clean with each new incarnation.

Anyway, the article says, "But in this century we have generated all these new chemicals and injected them into the environment, and suddenly the body is exposed to new substances that in some cases can interact with hormone receptors. The human species is totally unprepared for this, because it has never happened before." For instance there's "Dioxin, which is a byproduct of chemical manufacturing and of the paper-and-pulp industry, which is present at low levels nearly everywhere in the environment, and can cause an astonishing amount of damage." The article goes on to explain that rats given a very small dose of Dioxin during pregnancy produced males with a 60% reduced sperm count. A widely used pesticide, vinclozolin, emasculated the male pups.

Organic farmers avoid the pesticides which are in our supermarket food, but their produce still doesn't have the minerals we need.

Look, our bodies adapted to the foods and waters in the environment over millions of years. Now, just in the last few decades, we've stopped getting the minerals and vitamins our bodies were designed to use. The result is a wide range of illnesses and a cutting of our life span in half. This also has affected our immune systems, making us much less resistant to passing bugs and infections.

There is also the impact of pain, both physical and mental, which lowers our immune system. But there are some ways to reduce this substantially, thus keeping the immune system strong. I'll have to write an instruction book on how anyone can do that. It's not difficult, but it's not presently accepted by the medical-industrial complex. Your doctor may be as kindly as mine, but he does not have your best interests at heart. The medical industry only makes money when you get sick, so they have a $1.4 trillion stake in your getting sick. If all they had to do was repair people damaged in

Continued on page 19

A much better-engineered design resulted from his contributions. All builders will thank Gene for building a unit in parallel with the original prototype, thereby providing necessary unit-to-unit variables and a more refined design.

My NiCds are now in better condition than ever before. The Discharger is easy to duplicate and can save considerable hassle with your NiCds. Building it is fun and the result is rewarding. Build one for yourself!

Photo D. Completed board with all the parts mounted.

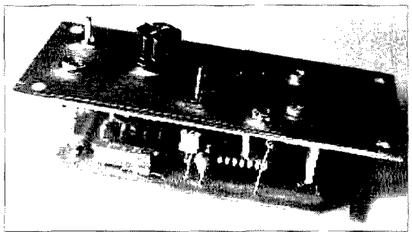

Photo E. The board mounted on the front panel, ready for paint and labeling.

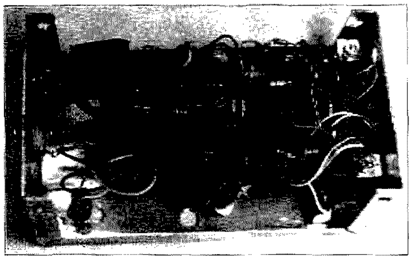

Photo F. WØDLQ's Discharger–standard construction technique.

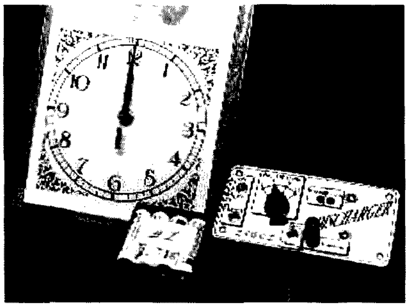

Photo G. The Discharger, with the clock, ready for operation.

Checkout Sequence

Conduct the following tests with a variable voltage supply in lieu of the battery pack.

1. Connect a 5 volt power supply to the battery connection points of the Discharger, observing proper polarity.
2. Set the Auto/Manual switch to the Auto position, and the # Cell switch to the #4 position.
3. When you turn on the power switch, you should see a very brief flash of the green LED, followed immediately by the red LED coming on and staying on.
4. If for some reason the red LED does not come on, put the switch momentarily in the Manual position, and then back to the Auto position.
5. Adjust the 20k pot for 3.08 volts on pin 4 of the LM339, with the red LED on.
6. Switch to #8 position, and the green LED should come on, and the voltage on pin 4 should drop noticeably.
7. Set the switch to #12 and the supply voltage to 15 volts, in that order.
8. If the red LED does not come on, switch momentarily to the Manual position, and then back to the Auto position.
9. Slowly decrease the supply voltage through 12 volts. The green LED should come on when the supply voltage is close to 12. Note that going up from below 12 volts will require higher voltage to get the red LED to come on. This is normal.
10. Switch to position #10, making sure the red LED comes on.
11. Slowly decrease the supply voltage through 10 volts. The green LED should come on when the voltage is close to 10.
12. Switch to #8 position, making sure the red LED comes on.
13. Slowly decrease the supply voltage through 8. The green LED should come on at 8 volts.
14. Recheck the #4 supply voltage operation to see if it has changed. If necessary, readjust the 20k pot so that the green LED switches on just as the voltage is decreased to 4 volts.
15. Measure and record the current drawn by the Discharger while the red LED is on. It should be near 200 mA.

Battery Discharge Data

Battery Pack	Size	Discharge #	mA-Hrs.

NEVER SAY DIE
Continued from page 17

accidents, the industry would be more like a $500 million complex, with almost no pharmaceutical companies, and a tenth as many hospitals. Calling it a "health care" industry is as honest as calling the War Department the Department of Defense. Har-de-har. Let's really be nice and call it the Peace Department and have a Secretary of Peace.

Wealth

As with health, accruing wealth calls for a change in the life patterns which have been rather thoroughly ingrained. If you want to make more money than the lower middle class you are going to have to spend time doing the necessary homework. School? College? Forget it. Once you've learned to read, school is an enormous waste of time. Self-education is the key, and that means reading and asking questions.

If you have the guts to break your well-ingrained habits and start eating right, and learning, you can make all the money you want and have a darned good change to live to 150 in good health. Have you the willpower to not smoke that cigarette? To not swizzle another beer? To turn off the TV and read one of the books on my "You're Crazy if You Don't Read" list?

Have you ever bothered to read Napoleon Hill's *Think and Grow Rich* Pocket book? He first published it in 1937 and it's still in print. How about Parkinson's Laws? In Parkinson's *The Law and the Demand,* his Third Law points out that almost anyone can become a millionaire by the time they're 25 if they drop out of school at 15 and self-educate themselves from then on. That's the same thing I've been preaching.

The basic question is this: Are you a lemming or a pioneer? Getting a ham ticket shows a small sign of independence, so there may be an as yet unsmothered spark of guts somewhere within you. Our schools system and society in general put a heavy pressure on you to shut up and be a lemming. Don't make waves. If you ever work for a large corporation, any branch of the government, the military, or teach, you quickly find out how dangerous to your career wave-making and ideas can be. But in those directions lie enforced mediocrity and semi-poverty.

Our public school system was copied by our churches in the early 1800s from the Prussian model, which was designed to provide men for the Prussian army who would obey orders without question. The last thing the army or the church wanted to develop was a thinking population. Thinking equals trouble. The churches wanted unquestioning churchgoers and business needed people educated just enough to work in the factories of the industrial revolution.

The adventure of packet, ham satellite communications, the microwaves, foxhunting, and so on all provide an incentive to learn more about radio and electronics. Is it fear that's keeping you from exploring these new territories? Or stick-in-the-mudism? I'm always disappointed when giving talks at hamfests and I ask for a show of hands of those who are on packet. Those on RTTY? SSTV? Satellites? How many have worked more than 300 countries? How about going on a DXpedition?

No, they're on the local repeater. They call into a 75m net. 2m SSB? Nope. Meteor scatter DXing on 2m? Nope. Maybe some aurora contacts on 2? Okay, what do they know about M-PEG and compression algorithms? Why am I not seeing any hands?

Wisdom

How many people do you know who are really healthy? How many are wealthy? How many do you consider wise?

The response to my interview on the Art Bell talk radio show was encouraging and started me thinking about some sort of a newsletter or magazine devoted to helping people to make their lives better. But what could I do about procrastination? Most of us, even when we know what we're doing is destructive to our health or wealth, can't stop ourselves. Well, I'll eat this now and diet tomorrow. I'll watch the ball game today and exercise tomorrow. I'll put that new antenna up next week. Sure, I'd probably make more money if I'd read some books...and I will when I find time. Yes, I've been there and done that, so I know all about it personally.

As we get older and find our lives more and more restricted by the things we've done to our bodies, we finally start getting more interested in health. We start wanting to learn, at long last, about what food, water, air, exercise, sun, EMFs, poisons, and all that stuff we've pretty much ignored has done to us. And then, what the heck we can do about it now, if it isn't too late?

Some of us get angry when we find that the tobacco companies have knowingly been poisoning us. That the power companies have been doing ditto with their power lines. That the pharmaceutical companies, with the assistance of the FDA, NIH, WHO, AMA, and so on have been not only poisoning us, but doing their best to keep us from finding out how to be healthy. That scientists in general don't know what the heck they are talking about. And that our whole society is rigged to make sure that you don't ever make much money.

Do you think there is enough interest in breaking out of the all-pervasive, destructive pattern we've been living to support a newsletter? Probably not.

Skeptic

Now and then a book comes along that gets me all excited. "Wow!" stuff. Like the René book exposing the whole moon landing program as no more real than the "Apollo-13" movie. Which apparently was a documentary-type movie of a completely fictional event. The *NASA Mooned America* book will be on the next update of my list of

Wheelchair Mobile

Dave Skinner KC5NLK operates from his wheelchair.

Paul J. Graziani WD5BIV
8324 Leatrice Drive
Little Rock AR 72227

The CW class is about to begin when David KC5NLK and his dad, John KA5VAQ, arrive. David Skinner wheels into place, begins to set up his PC laptop, and prepares to copy code. After eight weeks of class he's confident he can nail down the 5 wpm exam. One week later he does, at the volunteer exam session.

Despite David's confinement to a wheelchair due to muscular dystrophy, he leads an active ham life. Dave can be found on the local repeaters, talking to some of his buddies. In addition, he works on a computer, using a specially designed mouse for input.

Photo A. Dave Skinner KC5NLK in his wheelchair mobile.

Because Dave did not want radio frequency (RF) hitting the back of his head and needed an antenna with some gain for use with his radio, His dad designed and built an antenna that uses an automobile up/down motor to raise and lower the whip. It enables Dave to use the higher gain antenna with higher power while keeping the RF well above his head. He can lower it to get through doorways and to miss those ceiling fans commonly used here in the South.

"Equipped with his laptop computer and VHF transceiver, David can be in either voice or digital communications from wherever he sits."

While on the subject of heat, only someone familiar with Arkansas summers knows the fierceness of the late June heat on the afternoon of Field Day. David was out there working the VHF station, chasing those contacts on an early evening E-skip. He also managed to enjoy the fellowship and traditional potluck dinner served by the Metropolitan Amateur Radio Club at its annual Field Day effort. David listened intently to the senior members of the Ozark Would Be Adventurers and Liars Club, who always meet on Saturday evening of Field Day. We now consider him a junior member along, with several of the other younger hams present.

He doesn't let his disability stand in his way. Dave has served as net control for the weekly Metropolitan Amateur Radio Club 2 meter net and participates in public service activities. He was recently elected Club Secretary for 1996. Aided by technology, Dave is able to contribute and participate with his fellow hams. He is currently working on upgrading to General Class.

He does seem like a young man in a hurry. If you don't believe it, just stand by while he zooms down the hall in his electric wheelchair mobile, living up to the tradition of teenage drivers. The batteries provide power for his chair motor, as well as for his on-board high-technology ham station.

Equipped with his laptop computer and VHF transceiver, David can be in either voice or digital communications from wherever he sits.

"He has been a real inspiration to other hams and a contributor to the club," said Kenneth Keplinger N5XLX, president of the Metropolitan Amateur Radio Club.

If you are passing through Little Rock, Arkansas, give a shout on the 146.07/67 WB5GFA repeater for KC5NLK. There's no telling where you'll find him in his mobile communications "shack."

NEVER SAY DIE

Continued from page 19

"books you're crazy if you don't read."

As soon as I read that book I called René and asked what else he had. A few days later *The Last Skeptic of Science* arrived. It's another page-turner I couldn't put down. It's self-published, 179p, 1995, $25. As soon as I read it I faxed René to send me some copies to make available through Radio Bookshop.

Why did I get so excited? Well, René (nom de plume) fearlessly tackles Newton, Einstein, Hawking, Hubble, et al and wins. Do you really, honestly believe that the moon causes our tides? Or that there really have been ice ages? Or that there is a gravity force? Or that there ever was a Big Bang? Or black holes? An expanding universe? Or hundreds of fundamental particles? Or that the earth's magnetic field has reversed itself? Or that we have the field because the earth is a big magnet? Or that volcanos are caused by leaks from the earth's molten interior? Or that the transmutation of elements is either impossible or difficult? That the speed of light is constant? That objects of different weights drop at the same acceleration in a vacuum? Or that the ice cap over Antarctica is millions of years old?

René does a masterful job of tackling things scientists (he calls them science philosophers) and most of the rest of us have been taught to accept as facts and laws, reducing them to exploded theories. If you are a heavy believer in the authority of the scientific establishment this is a book you'd better not read, just as his moon book is best not read by people who are true believers in the honesty of our government.

For instance, when I got a call from Len WA2IHI about his efforts to help get the word around on the Beck blood purifier, I mentioned the NASA book to him and he got a big laugh out of it. April Fool, right? So I suggested he stop reacting for a moment and think. Remember the photos and movies of our astronauts walking on the moon and the footprints we could plainly see? Sure. Well, have you ever walked in hot, dry sand? You don't leave any footprints, just dents. It takes moisture to hold sand or dirt in place to leave a footprint and the moon's surface is about 250°F during the two-week day, so it is as dry as anything is ever going to get. It certainly is not going to register footprints. Unless moon dirt, unlike any other dirt, dust, or sand ever discovered, has some magical properties which bind it together, allowing individual grains to stick to each other.

Len squirmed and then said that obviously moon dirt is different. It holds footprints and tire tracks. Sure, and to hell with facts. I hung up, chuckling.

René cites dozens of solid reasons why nobody has yet been able to visit the moon. After reading this book you'll have something to talk about on the air besides all that money you put into your big antenna.

Both the NASA exposé and the Skeptic book are $25 (plus $3 s/h) from Radio Bookshop. I'll be surprised if you don't add both of these to your list of the most exciting books you've ever read.

René's ideas tie in with what I've learned recently from other books on my recommended list, such as *The Big Bang Never Happened*, by Eric Lerner, *Footprints of the Gods*, by Graham Hancock, and so on.

Maybe you've watched some of the recent TV exposés of the way the pharmaceutical companies, in conjunction with the AMA, FDA, NIH, WHO, and so on have covered up inexpensive and effective cures for ulcers and epilepsy. If so, you can understand why I'm reading every book I can find on alternatives to the current sickness repair system, and perhaps why I have less and less faith in authority figures. And that particularly holds for Ph.D.s and our beloved government. I suppose I should have been warned, since Ph.D. stands for a doctor of philosophy, not science.

Little that I was taught about science in high school and college has stood the test of time. I was taught that our solar system got started when another sun passed close to ours and sucked off the stuff making the planets. And my college physics classes never once mentioned quantum mechanics.

Say, I hope you are enjoying being with me on my adventure into learning about our universe, health, and so on. I've always found it exciting to learn new things, and I have this drive to share the things I enjoy with as many others as I can. Amateur radio has provided me with endless adventure as I've learned about one new mode after another. I've had a ball DXing, DXpeditioning, and contesting. I'm frustrated at failing to get our Techs to upgrade and experience the thrill of working a VK or ZL on 75m phone, or the fun of making contacts through our ham satellites.

Upgrading Your Transmatch

Make your buddies sick with envy by adding a Ten-Tec tuning bridge.

Dan Hall KJ7FX
7819 N.E. 128th Ave.
Vancouver WA 98682

Much to Wayne's chagrin, any regular listener on the ham bands will find out in short order that the hot topic of conversation most evenings is equipment, and of all the equipment that hams love to talk about, antennas are number one. If you listen long enough you will also find out that there are really only two basic types of hams: those who buy the biggest, tallest, and most expensive antenna systems their spouses and their communities will allow and then talk about them incessantly; and those who don't, and talk about *that* incessantly. I fall into the latter group. There are a variety of reasons for this, not the least of which is that I'm a ham because I love to build things, and antennas are among the few pieces of gear that won't cost an arm and a leg to fool with. Besides, they can be as simple or as complex as your mother-in-law. In other words, any idiot can build one—even I can.

When I first began to experiment with odd bits of wire on slippery rooftops, I was fortunate enough to own one of those remarkable little radios from Japan that included, among other extraordinary features, a little bitty antenna tuner that would whir and growl and click its way to a perfect match between its transmission line and my rooftop creations. Alas, as the last sunspot peak began to wane I was forced back onto resonant antennas, first by the addition of a linear amplifier and second by trading up to a transceiver with a bit more basic receiver performance. I now drive a new American rig that doesn't have one of those fancy tuners. Oh well.

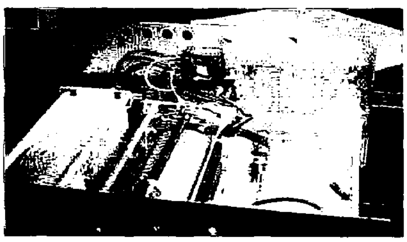

Photo A. Install the relay, RCA power jack, and a fuse on the back panel of the transmatch.

Clearly what was required here was an external transmatch of some sort so that I could deliver all those gobs of power to my loops and longwires and windoms. The big shock came when I began to price automatic antenna tuners for kilowatt stations. I hoped there was a less painful way...and there was.

Tuning a transmatch

I had known for some time that an ordinary noise bridge, of the type used to measure the impedance of an antenna circuit, could be used as an aid to tuning a transmatch. You will recall that these devices, available commercially and described numerous times in amateur publications, inject a noise signal into a bridge circuit comprised of an unknown antenna impedance and a variable capacitance in series with a variable resistance. While listening to the noise at the transceiver, you adjust the variable capacitor and resistor until a sharp null is obtained, then read the calibrated values of these components and modify the antenna to suit. If you substitute a 50 Ω resistor for the variable R/C devices and insert a transmatch in series with the unknown antenna impedance in this circuit you will have created a great aid to tuning a transmatch. Now you simply adjust the variable portion of the unknown arm of the bridge until the null is obtained. The transceiver will then be looking into a 50 Ω load.

All of this without emitting a lot of rude and offensive signal onto already crowded bands! This was important to me. With one or two possible exceptions, there is nothing quite so annoying as a tuner-upper doing his thing right in the middle of an ongoing QSO or net operation. Even more irksome, perhaps, is the knowledge that the guilty party has probably followed the old admonition to move a little off frequency to tune up; he's not going to be bothering his buddies a bit, but doesn't mind dumping a little QRM on the other guy as long as it's anonymous.

The Ten-Tec bridge

So along comes TKits, a division of Ten-Tec, with a new product line that serves up a simple circuit on a board, complete with parts for stuffing and an excellent instruction manual, at rock-bottom prices. I thought that their kit #1051, a "Transmatch Tuning Bridge," and my old Murch 1.5 kW "Ultimate Transmatch" ought to team up for the perfect "almost automatic" antenna tuner. They do, and it works terrific!

There's a phrase I first encountered in the works of Lewis Carroll that ring true for any project of this sort: "Begin at the beginning, then continue on until the end, then stop!" Having said that, however, there are a few words of caution and encouragement and some advice of a general sort that I'd like to impart by way of preparation for the journey. First, just about any antenna tuner would be suitable for this project, as long as there's some extra room to mount the circuit board and its interface to the tuner "under the hood." Secondly, if you're made like most of us you are probably a little uneasy about poking

Never Say Die
Continued from page 21

Selenium

As I read the latest stack of club newsletters I kept seeing obits for local hams who have died of heart failure or stroke. Veterinarians solved that problem for animals decades ago. Farm animals don't die of heart attacks or strokes. Farmers add pellets with the minerals which are missing from today's crops to their animals' feed. But don't ask your doctor about preventative medicine, vitamins or minerals—they're not his field. If doctors were taught anything about health maintenance instead of just about repairs they wouldn't be dying an average of 17 years younger than the rest of us.

They're taught how to treat symptoms.

Cows, pigs and horses don't die of heart attacks or Alzheimer's because farmers give them the minerals they need with their feed. Well, that's something for you to think about as the ambulance rushes you to the emergency room. That old ounce of prevention. Or more likely, 50 mg of selenium or some other missing mineral that's critically important to your body's function.

No, I'm no MD, nor even a DVM, so I don't ask you to believe me. But I recommend that you do your homework the way I have. I realize that you may not have much time to read, what with your time on the air, a little time at work, watching ball games and sitcoms — all making you a living example of the boiled frog syndrome: If you drop a frog into boiling water, he'll jump right out. But if you put him in warm water with a fire under it he'll enjoy the warmth until he's boiled.

And that's the way it is with our smoking, using drugs, and eating food that lacks the basic minerals and vitamins our bodies developed dependencies on, over millennia of design. Our bodies were designed to work on raw wild foods. They were never designed to cope with coffee and doughnuts or Big Macs and fries. So, either we have to figure some way to get our bodies the materials they need, or settle for half a life. The expression "You are what you eat," is right.

The Silent Keys column doesn't explain what SK'd the recipient of this final ARRL Award, but club newsletters usually go into more detail. I'm still disappointed at reading about hams who have done much for the hobby only in club newsletter obits. What a shame!

For instance, in the "Badger State Smoke Signals" there was a very nice obit about Travis Baird W9VQD. Travis stroked out (a mineral lack). He was into music, opera, speed skating, photography, sailing, football, computers, the violin, ATV, and so on. Now he's gone.

Twenty of the 73 books on my list of "books you're crazy if you don't read" are health oriented. The most important is *Maximize Immunity* by Dr. Bruno Comby. I got a fax from him this morning saying he's planning on moving to the US to establish a healthy-living community. If you read *The Secrets of the Soil*, another of my recommended books, you'll find out how to grow food that has the missing minerals.

Ever since the invention of the flush toilet we've been getting rid of the minerals in our crops instead of refertilizing our fields with them, as people did up until this century. Now we use chemicals as fertilizer, and we're suffering the consequences.

Hmm, I wonder how many of you grew up in the country with a backhouse and had to shovel out the privy every spring? My family's farm in Bethlehem, NH, had no running water and no electricity, so I know what it is to take a flashlight out to the privy in back of the barn at night in the rain. And there was no heat until the first one up (me) started the fire in the kitchen stove with newspaper, kindling, and some kerosene to get the wood going fast. And another fire in the living room fireplace, when it was really cold. While the stove was warming up I'd refill the kerosene lamps. The stove had a water tank at one end, so once the water was warm enough I'd scoop some out into a five-gallon watering can. Then, in the summer kitchen, out by the woodpile, I'd hoist the can over my head with a pulley and take a fast shower. That part of the house was unheated by the stove, so five gallons of water was plenty.

America At War!

Short quiz: What is the most expensive war in American
Continued on page 27

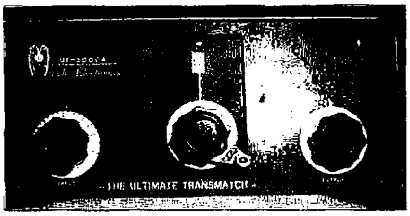

Photo B. Install the switch on the front panel.

holes in the front panel of a piece of factory-built gear. Don't be. There aren't many genuine collectors' items out there, and if you had one you would already know it. Besides, we are going to do an absolutely superb job of this and will actually increase the value of the piece. Finally, and this is very important, there is an even older saying that goes something like "One cannot make chicken soup out of chicken manure." We will need to be willing to acquire a few new tools if our finished project is to have the quality that we desire. See the sidebar.

The first thing I noticed as I unpacked the kit was that Ten-Tec had gone to great pains to provide decent documentation. Over the years I have assembled a number of projects that were hailed as marvelous in advertising copy, but proved to be largely design-and-build efforts when they hit the bench. Not so the TKit! The instruction manual reminded me a bit of the old Heathkit manuals: offset printed, well organized, and intended to be a permanent addition to the shack library. If I have any bone at all to pick with its authors, it's that they either failed to recognize or forgot to mention that the tuning bridge will not work if your receiver's noise blanker is engaged; its manufacturer actually intended it to be that way. Mash the old N.B. off button, however, and you'll have an abundance of noise that you can tune by. In any case, read the manual thoroughly and use the check-off format as you work through stuffing the board. Trust me–follow this advice and you'll have far less trouble to shoot later, and you'll have a more enjoyable experience to boot.

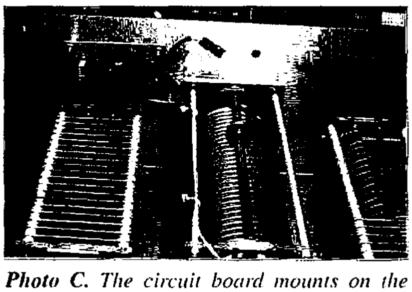

Photo C. The circuit board mounts on the back of the front panel.

Assembly

Before stuffing the board, you should lift the hood on the old transmatch and find out what kind of room we have for parts placement. This an important step, by the way, not only for this project but for any that you may take on. I've had a number of discouraging setbacks over the years when my impetuous nature urged me to leap forward before I'd even determined in which direction forward lay! Planning is more important to a satisfying outcome here than even the most perfectly soldered joint. We can easily re-solder a cold joint but it's always tougher to rip it all out and start over when we've made a haphazard start. In any case, start by taking stock of the total number of components and their possible locations within the unit.

You will have to decide whether to use a relay or a heavy duty switch to transfer between the tuning and transmitting functions. The decision was easy in my case; I already had the relay. Bear in mind, though, that using manual switching will require that you route high power RF to some point in the case where the switch can be located so as to allow easy manipulation of its handle. It's not as easy as it sounds, but it's certainly possible given some care in the routing of RG-8. Don't use RG-58 or other mini types in this application; they may not handle the high voltages typically found inside transmatches. On the other hand, use of a relay should allow placement of the transfer function directly adjacent to the input jack from the transmitter. The wiring diagram in the instruction manual illustrates the appropriate hookup. Use the normally closed contacts for the transmit mode and don't worry about the relay coming apart here; we are not switching RF, only transmitting when the contacts are at rest. By the way, you may want to avoid using a relay socket here. It will only add unnecessary cost and bulk in the installation. You can firmly attach the relay to the case with silicone adhesive and then solder directly to the pins (see **Photo A**).

While in the neighborhood of the back of the case, give some thought to how you will power the circuit board and the relay (if used). Though a 9 volt battery can certainly be used, most of us have a source of 13.8 volts around the shack with enough extra juice to power a project like this easily. I use RCA type jacks and plugs for low voltage DC at my station, with good results. Inexpensive audio cables are handy for feeders to various gear; just make sure that everything is plugged in properly before powering up, and that each source jack is adequately fused. In any case, drill a hole in the back panel of your tuner to accommodate whatever power jack you decide to use. Be careful not to drill into any components within; use a wood block if necessary to shield stuff from accidental puncture. It's amazing how deeply a 1/16th pilot bit can penetrate before either pain or dismay can persuade the brain that a pull-back response is in order.

"There is no surer way of letting the smoke out of one of these little ICs than sticking it in the holes with the notch at the wrong end."

Now that you have power it's time to locate and install the power switch. The switch I used is a two-pole unit so that I can energize the transfer relay and the circuit board with a single handle. It can be located at any convenient point on the front panel. Notice that most of these small switches have a tiny indexing groove on the barrel that is supposed to key into a tab protruding from the circumference of the hole cut to accept it. (What?) Never mind. I don't know anyone who has one of those punches. Just drill a tight round hole and use the hardware that came with the switch to make the most secure fit that you can. The object here is to keep the thing from spinning in its hole so that you don't know which way is on. A dab of silicone adhesive on either side of the switch body will keep things snug. Use great

Tool Acquisition Program for the Beginner

If you are reading this, you no doubt have acquired over the course of your life a conglomeration of tools with which you amaze everyone. You can perform such stunts as: extracting an errant toothpaste cap from the depths of a bathroom sink drain, replacing an electric light bulb from the front of an automobile, or inadvertently flipping the odd hamburger patty from the backyard grill into range of the family Rottweiler. These tools will not do. We will not be tightening screws here with a butter knife. If one truly aspires to be a genuine, true blue, Double Throwdown Electronical Wizard, then one must acquire a simple kit of quality tools. Rather than try to describe every item that should comprise this kit, I will profile a few that I have found helpful, if not essential, for a project of this type.

The first tool on my "must" list is always a decent multimeter. There is only one brand to buy, as far as I'm concerned, and that's Fluke. It's probably not kosher to plug a brand like this, and there are probably other good units out there, but that's my opinion and I'll stick to it. They are spendy when new, but are available reasonably on the used market. Try the back pages of *73* or *Ham Trader Yellow Sheets*.

Make something to hold the PC board still while you stuff it or solder components in. I knew a guy who didn't have one of these and he is now a Silent Key! Honestly, you cannot stay sane and complete a project like this without something that performs this function. Get a piece of 1/4-inch steel rod about 10 inches long. Bend a 90° turn about 2 inches from one end of it and jam the other end into a hole drilled in a block of wood. Use a hose clamp to fasten an ordinary spring clip to the end sticking up and you're done. These clips are called "Pony Clamps" and they are available in the woodworking section of large hardware stores. Send me $12 and I'll round this stuff up for you. If you feel like you just can't handle it, send me $32 and I'll send you the completed work clamp. Take heed, though, I'm making an enormous profit here, on something you could easily do yourself.

Ever notice how a drill bit worms around all over the face of your work before it decides to dig in and perform its function? Or after having drilled the holes for a row of indicator lights, you discover that they look like a tiny slalom course laid out on your panel front? The only way I know of to achieve acceptable results when fabricating the sheet metal for a project is to carefully, thoughtfully lay out each penetration, and then double-check each part for fit and clearance inside the case. Then get a spring-loaded center punch. To use one, place the hardened tip exactly where you are going to drill your hole and then press down firmly until the escapement mechanism lets go inside. *Voilà!* A perfectly centered punch mark to guide the pilot bit.

Now about those holes. Any hole drilled through a chassis starts life as a 1/16th-inch diameter pilot hole and increases size by stages until the proper fit is achieved. Take a look at **Photo E.** The two tools on the bottom are known as step bits and they are invaluable for rapidly producing just the right hole to suit the situation. After use, wrap them in a few turns of electrical tape so that they won't lose their edge rolling amongst all the detritus at the bottom of your tool box. The third device from the bottom is the aforementioned spring-loaded center punch. The tool on the top is a deburring tool, or a countersink. All right, as a countersink it leaves a little to be desired, but it does a whale of a job knocking down those razor-sharp little fuzzies that adhere to the edges of a freshly drilled hole.

Photo D. *The workbench, with a meter, soldering iron, center punch, an equipment clamp, and bits.*

Buy a decent soldering iron, or make a cheap temperature control unit for a cheap soldering iron by using an ordinary incandescent light dimmer. I bought my fancy Weller iron at an electronics surplus joint for $5. Get a coaxial cable stripper! Mine is made by Corex, has replaceable blades, and cost under $20. Get a set of those tiny little jewelers' files. If you do drill a hole slightly off-center, sometimes you can get things back in line with a little judicious filing. Wear safety glasses, please. I've taken metal particles in the eye twice in my life, and glass beads on one occasion. The glass bead incident occurred in spite of the use of glasses. Believe me, what they do to you down at the emergency room sucks all the way through to the end, not to mention the possible consequences to your vision if you're not as lucky as I was. Be safe and have fun.

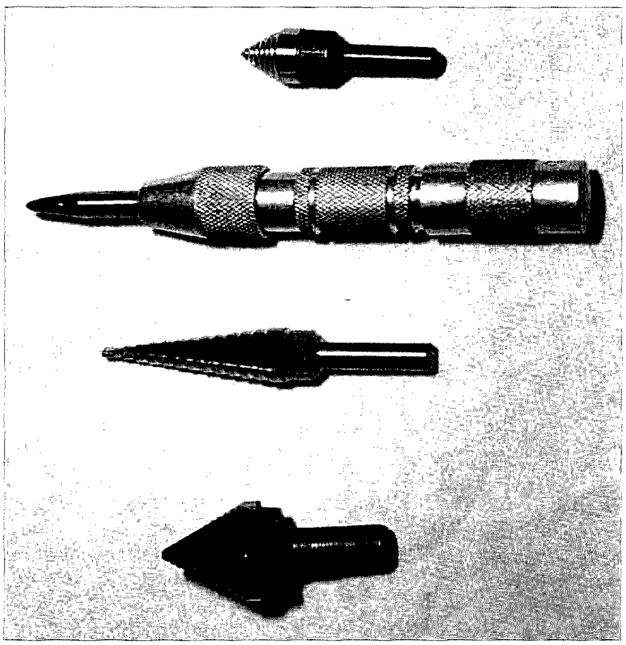

Photo E. *Center punch and three very handy drill bits.*

care tightening the front nut to avoid leaving nasty gouges in the panel face with your pliers (see **Photos B and C**).

Next, you have to decide where the circuit board goes. A nice trick is to use existing hardware, if that's possible. You may be able to fabricate a couple of small angle clips to allow attachment of the board to an existing component mount. Be aware that you must maintain clearance between live parts and grounded surfaces here. I used common standoffs, available at Radio Shack™, but have frequently used short pieces of plastic tubing, cut to length, with long screws to match. If you're fortunate, you will have enough room on the floor of the chassis or rear panel to mount the thing, and still route all the conductors that terminate there smoothly. Use some common sense, though. It is neither desirable nor necessary to make elaborate 90° turns everywhere, just to lead a few wires across the inside of a piece of gear. You will want to follow some sort of plan that keeps things together, takes advantage of a general structural element perhaps, or uses those little stickyback pad eyes to tie things down with wire wraps. Should you choose to install the board against the backside of the front panel like I did, there is a bonus possibility that you can mount the circuit's LED indicator directly to the circuit board (see **Photo C**). If you do, just make sure that you lay out the mounting holes and the LED hole using the board as a template before you stuff it. Then select standoffs of a length sufficient to allow just the tip of the LED to protrude through the hole in the panel. Also, remember to solder the LED onto the side of the board opposite the rest of the components, leaving its leads as long as possible. This will allow access to the adjustment pots after the unit is mounted in place.

Go ahead and stuff the board now. If you've read the sidebar you know how important it is that you have some way to hold the circuit board while you are working on it. Follow directions, placing the parts precisely as they are laid out for you in the manual. Pay particular attention to placing the right stuff in the right holes in the right direction. You know, it never ceases to amaze me how frequently I get ICs plugged in the wrong way. There is probably no surer way of letting the smoke out of one of these little devils than sticking it in the holes with the notch at the wrong end. If you do, don't worry. The little 556 dual-timer that this circuit uses is available at Radio Shack for about a buck. Better pick up two...and a socket in case your luck stays bad. I substituted a 47 Ω resistor for R-12. (Actually, it turned out to be a 49 Ω one after I dug through the drawer and found one that tested a bit fat). R-12 would normally be an adjustable resistor set to 50 Ω; this is the reference value in the bridge made up of the 50 Ω input to your transceiver and the tuner/antenna combo.

When everything is on board and soldered up tight it's time to attach the various conductors that are needed to wire the thing together. The kit comes with a small amount of RG-174 mini 50 Ω coax to guide the RF on and off the circuit board. There wasn't enough to complete my installation, but it was available locally, so I was able to pick up more. If necessary you can order some from your favorite mail order supplier. Lay in a fair amount of it—it comes in handy. Make all the connections to the board while it is on the bench. I chose to use both positive and negative conductors for DC rather than rely on chassis ground for negative return. Leave the leads long so that they can be cut to length, tinned, and soldered up tight after they have been led to their locations and tied snugly into place. The manual suggests the *optional* placement of a fuse between the transceiver and its input to the board. This is not an option! Buy a fuse holder and *put it in*. I forget now and then to turn off the tuning bridge before transmitting. This is not good! With the fuse in place, though, there probably won't be any damage.

Well, have fun—I certainly did. After you have soldered up the last joint, take a few minutes to verify that everything is connected to its proper place. When first powering a new project I usually leave the cover off and keep a sharp eye out for those little telltale puffs of smoke or glowing wires that indicate a problem. With a project of this type you are not likely to encounter any, but if you do, don't worry. Nothing on this board is difficult to find locally (with the possible exception of R-12/13). If you inadvertently transmit into the bridge, even with the fuse protection, and it quits working, check out R-12; you've probably let the smoke out. Stick a 47 Ω fixed resistor in its place as previously mentioned and you're back in business. 73

Continued from page 23

history? It is a war that cost more than WWII, Korea, and Vietnam combined. Hint...it's one we lost. One we lost in a big way. One that has brought about catastrophic changes in our country.

It's President Lyndon Johnson's War on Poverty. Welfare. Welfare mothers. Hey, it's *your* money your politicians are doling out. Over $5 trillion so far, with no end in sight.

When the government pays women welfare benefits equivalent to $12 an hour, two-and-a-half times the minimum wage, in New York and Washington, not to work, what do you think this does to wages in those areas? To be "entitled" to this largess at our expense the women have to have children...the more the better... no job, and no husband who's working.

In 39 states welfare benefits are equivalent to about $16,600 a year. In eight it's over $20,000.

I've already written about a woman with two children who is on welfare in my small New Hampshire town. Her food and apartment are provided, plus schooling for one child, complete with a paid driver to ferry the child to school and back every day. The woman is bitterly complaining that her welfare-provided cable TV only gives her two paid channels. Oh yes, her husband is working, but they are "separated." One of my ex-employees' wives gets $50 a week just to drive the child to school. A recent exposé on welfare showed a couple of women in Laconia (NH) sitting in their apartments getting fat on this same system. Work? And lose all those benefits? You've got to be kidding!

So we complain about the single mothers. We complain about the loss of family values that's turning out one generation after another of uneducated welfare mothers and their progeny with no incentive or skills to work. Compassion gone berserk, and to hell with the "survival of the fittest" concept. We're making sure that the least fit survive and proliferate, dragging us all down.

What can *you* do about this mess you've meekly let fester? Two things. First, we've got to stop Congress from making things worse. Second, we've got to get Congress to strike out the laws they've made that are screwing us up. My bumper sticker approach to this is to start with Green's NRA: Never Re-elect Anyone! Get those bribed (via lobbyists) scoundrels out of Washington. Let's build a whole new breed of one-term politicians.

But most important is to take a few days off from watching mind-numbing TV and educate yourself. There are some damned good books which will help you understand what's gone wrong with our school system, with the war on poverty, the war on drugs, our terrible so-called health-care system, our "correctional institutions," and so on. Hey, we have the potential for having a pretty good country, but it's going to take a lot of work by a lot of people to make it happen.

The multi-level marketing (chain-letter) approach will work for us. First you educate yourself. Then you get two or three other people started being educated. And they do the same for two or three more. The next thing you know, we'll have a movement.

Say, that's not a bad idea for rescuing amateur radio from what now seems like an inevitable doom. If we could get across the idea that every new ham has a responsibility to make sure that he or she elmers at least two new hams, and that each of those do the same, we'd start growing again and have at least a prayer of keeping our hobby going.

In addition to growing local ham clubs, I'd like to see local political action clubs (PACs) get going. Members would be encouraged to read a book and report on it at the next meeting. There are an awful lot of books out there, but only a small percentage of them are interesting and educational. By distributing the work of separating the wheat from the chaff, a group can easily do something that no one person could accomplish.

The same goes for ham clubs too. How about a club project to sort out all of the ham-oriented books and report on them at club meetings? I'd suggest the club buy the books for the club library and then have a couple of the members read each new book and report on it. If the club can organize the bulk buying of the top-notch books, they can pass along the normal discount to the members. For most books this runs around 40-50% off the list price, allowing club members to build first-rate technical libraries at a big saving.

The next thing you know some entrepreneur will start collecting the book reports and submit them to me for publication. And I'll pay for 'em. The resulting sale of the better books will help discourage publishers from unloading crap on us, and will encourage the writing of even better books.

How about it? What book having something to do with amateur radio, electronics, or communications have you read that was really exciting and outstanding? My $5 list of 73 "books you're crazy if you don't read" doesn't have any ham books, but that's because I haven't found any that are outstanding so far. My list does cover a wide variety of topics. Reading these books will beat the heck out of a college education. And be cheaper, and take a lot less time.

Perhaps I've let my idealism run away with me in even suggesting that we try to run our country on reason instead of fanaticism. Maybe screaming protesters and terrorism are the rule of the day and reason passé.

Anyway, if you feel that people who prefer not to work are worth $335 billion of your money being taken out of your paycheck every year, then go back and watch that ball game on TV, or get on the air and ask a few more hams what antenna they're using. As long as you're satisfied that you're getting your money's worth it's no problem.

Continued on page 37

Number 28 on your Feedback card

Foxhunting Deluxe

A compact antenna switching unit for Doppler DF.

Breckinridge S. Smith K4CHE
104 Brookfield Drive
Dover DE 19901

I've been interested in Doppler DF systems for foxhunting for several years. No, let me rephrase that. I have been *obsessed* with Doppler DF systems. Ask my wife—she'll tell you. So when I read KØOV Joe Moell's "A Good Doppler Gets Better" in the April 1995 *73*, the antenna switching techniques got my attention. After all, if Joe uses two diodes to switch each antenna for his Doppler system instead of one, it has to be better, right?

I have never been satisfied with large VHF Doppler antenna systems that are mounted on the car roof. Most of these systems consist of a large plywood or aluminum plate with appendages to improve the ground plane. The switching circuits are usually mounted somewhere under the plane. On UHF the overall size is smaller and you have less wind loading, but on VHF the larger size can be hard to manage. I lost a large VHF array while driving during a hunt, and that cured me of temporarily mounting big heavy things on top of my car. When that Doppler antenna package became airborne it looked like a square flying saucer (and it barely missed wiping out the car behind me).

Joe KØOV then published his article "Wideband Doppler, Part 2" in the June 1995 *73* describing his modification of CB magnetic mounts and mounting the antenna switching circuits inside the Roanoke Doppler chassis inside his car. This looked like a better system since mag mounts have to be better than my flying saucer. I wasn't really happy with the CB mag mounts, but I decided to press on with the project, build the switcher, and shop around for a better magnetic mount antenna to modify.

Photo A. The Dick Smith Doppler unit is on the dash. K4CHE uses the DF for commercial stuck-mike hunting, etc., in Delaware.

The problem with putting the antenna switching circuit inside your system box in your cockpit is that you now have *four* long coax lines running across the roof and down inside the vehicle, over the seats, across the dash, etc. Trying to get these four long antenna feedlines electrically equal is next to impossible. Additionally, on two of the units I tested, these long feedlines appeared to couple to each other and cause reflections which affected the bearings. I decided to build a remote switcher so I could eliminate most of those feedlines. Since I already have several holes in my van roof (I told you I was a DF fanatic), I was able to put the four mag mounts near the hole and mount the new switcher box just inside the roof. That provided short feedlines, good decoupling from the antennas, and a neat installation.

Circuit construction

The small switcher unit puzzled me for a while. On the KØOV dual diode switcher circuit the majority of the surface board is at a positive 3.7 volts DC potential, so it has to be isolated from ground. Joe solved the construction problem in his "Part Two" article by using a "Dremel Moto-Tool© as a router to insulate the center of the board where the four single-hole coax fittings mount."

So I built a remote-mounted switcher box using copper-clad board and used the same Dremel tool routing techniques. Basically, I used a double-sided PC board and cut it to fit the top of a standard Bud box. Using a double-sided board and a sealed box made the circuit

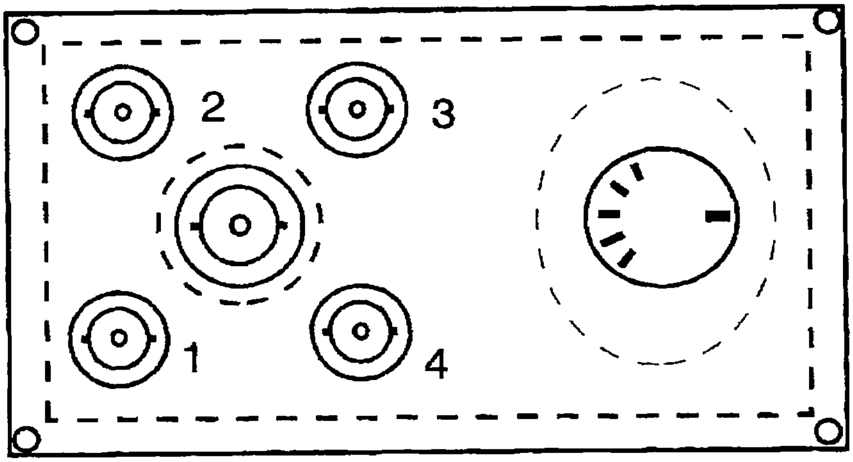

Fig. 1. Top view of the switcher.

well-shielded. BNC connectors reduced the board size and increased the connector reliability. Routing techniques were used to isolate the hot 3.7 volt area from the box case. These routed areas are indicated by the dashed lines in **Fig. 1**. The holes to mount the board to the aluminum box are drilled outside the routed areas and the DIN connector mount area is also isolated. The routed area is on both sides of the double-clad PC board. The center BNC connector for the receiver coax is isolated from the board inside its own dashed circle (routed) area. Use high quality Teflon™ BNC connectors so you can solder the nuts to keep them tight and have reliable connections. You will have to refer to Joe's schematic in his column "Homing In" in the April 1995 *73* to get the big picture. The component values are published in both the April and June (1995) issues of *73*.

The pin diodes all are mounted and connected between each antenna's BNC center pin and a small insulated standoff connection point. Remember that the cathode end goes to the insulated standoff connection point. The 680 pF RF coupling caps (C101-104) are then connected from the insulated standoff connection point to the pin of the center BNC to feed the receiver. Switching signals are supplied through the RF chokes (L101-104) which are connected between the pin diode/coupling cap standoffs and the choke input bypass capacitors (C105-108) and then a connection is made to the appropriate pin on the DIN connector. See **Fig. 2**. On most of my VHF/UHF projects I like to wind my own chokes to the frequency that I plan to use. Joe's directions for winding the chokes using a 2 meter quarter-wave of wire (19.5 inches) are in the June 1995 issue.

"Do away with the octopus—eliminate the flying saucer with Doppler DF!"

I soldered the bottom of each choke input bypass capacitor by a short lead directly to the copper board and mounted these caps vertically on their ends. These vertically mounted bypass capacitors now serve as mounts for the other ends of the chokes as well as performing their bypassing function. See **Fig. 2**.

If you're careful you'll wind up with equal lead lengths on the coupling capacitors and the whole switching circuit will be symmetrical. When soldering your wires on the DIN connectors, remember that the pins are not in order and DIN pin labeled number 1 goes to antenna number 1, etc. Don't forget C109, which provides an RF path from the routed center receiver BNC mount area to the main board area. You might want to install and solder this capacitor first, as it may be hard to get to later. Choke L105, which provides the +3.7 volts to the main board "P" area, can be soldered last.

Magnetic mount modifications

My preference is the Motorola magnetic mount. It has a 1/8-inch rim that allows you to grasp it easily for removal. In addition, the mount is hollow in the center. The 1-1/4-inch hole in the center can be accessed by cutting through the plastic that covers the magnet's bottom. This large access hole makes it easy to modify the interior, and later on you can even change the feedline (after you've slammed the RG-58 feedlines in your door a hundred times).

Motorola provides different antenna whips that are cut for different frequency segments: the low split whip (see the Parts Resources at the end of this article) covers 144 to 152 MHz, with a center frequency of 148. I have used these precut antennas without any problems, even though the center frequency is a little high for the ham band. There are other brands of whip kits available that will fit the Motorola mount. Coverage of the entire amateur band and beyond can be accomplished with an Antenna Specialist quarter-wave kit (part number ASP695). This antenna comes with a .072 diameter whip that can be trimmed and the hardware threads are compatible with the Motorola mount. With this antenna kit you could use different lengths of piano wire whips for each VHF segment you want to cover.

Modifying the Motorola mount is easy. Cut a circle in the clear plastic bottom cover. Carefully and quickly unsolder the center conductor from the center pin, using a good-sized iron. Let the center insulation cool and then bend the center conductor away from the center pin and mount your pin diode from the center conductor to the center pin of the mount.

Then mount the 270-ohm resistor from the shield clamp to the center pin. Use a piece of tape for insulation under the diode and resistor. Using this construction technique you will wind up with very short resistor and diode leads, so it's easy to keep lead lengths the same length on all of the mounts. After the mag mount surgery is over, repair the access hole with mailing tape—the clear tape that is 2 inches wide. You might want to put on an additional layer of clear tape on the bottom of your mount to protect your car roof and to further insulate the mount from the vehicle. Remember, the ground portion of the mag mount is at a positive 3.7 volts.

Testing

I was worried about how much noise might be generated by the extra

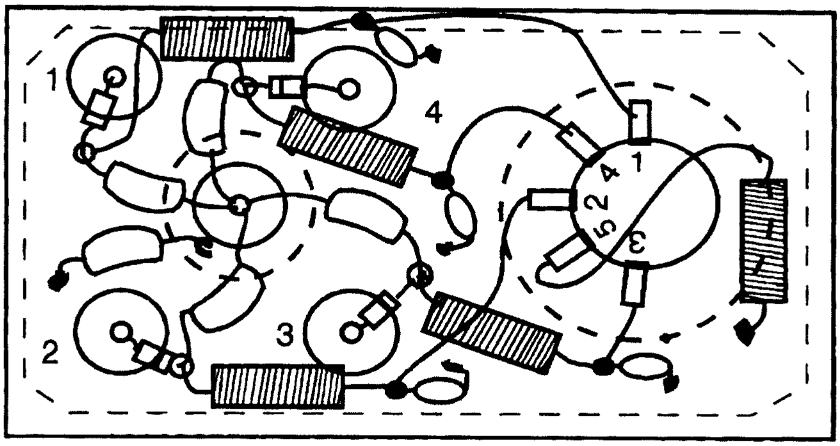

Fig. 2. Bottom view of switcher.

switching diodes, and their effect on the overall sensitivity of the system. After several tests out in the field I couldn't hear any noise increase due to the switching system with it mounted just inside the van cockpit, directly under the antennas.

Using my Dick Smith Doppler I mounted test connectors for the original switcher and the KØOV dual-diode circuit and ran comparison tests. With the dual-diode switching, the overall sensitivity of my Dick Smith Doppler system increased several microvolts. Additional tests with the Roanoke produced the same sensitivity and I could actually get some indication of stations that were well down in the noise. This was more evident on my Dick Smith system as it has 32 LEDs and appears to be more responsive visually to weak signal detection, as opposed to the 16 LEDs of my N6ZAV display. I know I will get a lot of comments about the 32 LEDs, but I like to see multipath to analyze it, and with the 32-LED display you get more information. In addition, with the 32-LED Dick Smith and the inherent "circling LED" you know when you are detecting a weak signal because the circling LED stops circling on a noisy weak signal and presents you with a multiple LED segment that just sort of jiggles back and forth, providing you with a rough direction indication.

When testing your mag mounts and remote switcher, a good troubleshooting hint furnished by KØOV is that you should have a couple of volts on each antenna (less than 3.7 volts due to the diode drop), and the voltages on each antenna should be equal if the diodes are OK. A 16-inch spacing seems to be best between each antenna, but Joe published "18 inches" in the June issue. With the mag mounts you can experiment with the spacing and reach your own conclusion. RF near-field testing with a 25-watt signal from two feet away did not blow any switching diodes.

Get out the Dremel tool; start routing. Now you can do away with those "octopus" leads that are strung across the seats and/or eliminate the flying saucer mounted on top of the vehicle. If you are new to Doppler, this system will solve the antenna dilemma. Many thanks to Sam K3BY who assisted in the testing and building of duplicate switching units and antennas. Good hunting.

Parts Resources

Diodes, chokes etc. are listed in the reference articles.

Motorola magnetic mounts can be ordered direct from the Motorola parts division at 1-800-422-4210. Motorola part number for the mag mount with 12 feet of RG-58 is 01-80355A91. Motorola part number for the lo-split whip (144-152 MHz not adjustable) and chrome base nut is 01-80352A06.

The Bud "Econoboxes" part number is CU-124 and can be ordered from Allied at 1-800-433-5700. Ask for Allied stock number 736-3600.

An Antenna Specialist whip kit that can be trimmed is manufacturer part number ASP695 and is available from Tessco, 1-800-472-7373. Ask for Tessco part number 94090.

Number 32 on your Feedback card

The 2 Meter Diamond Beam

It could be a real gem in the rough.

Thomas M. Hart AD1B
54 Hermaine Ave.
Dedham MA 02026

While reading the ARRL *Antenna Compendium Volume 2*, I encountered an antenna design I hadn't seen before. In an attempt to minimize the footprint of horizontally polarized HF beams, G.A. Bird G4ZU used a linear driven element in conjunction with a director and a reflector bent at 90° angles. Refer to **Fig. 1** for more information about the diamond shape of the antenna.

A number of other experimenters have proposed variations of beam antennas without planar parallel element designs. In his book *HF Antennas for All Locations*, Les Moxon provides information on at least three beams featuring elements that are bent in a variety of angles. In the RSGB text *High Frequency Antenna Collection*, Erwin David G4LQI describes a two-element beam that features acute-angled elements. A final design that has been popular is the X-Beam described in the *Antenna Compendium Volume 1* and in the periodical literature. The tails on the X-Beam apparently contribute to the emphasis of front and rear lobes; a straight element X-Beam has four equal lobes (see the Moxon text for details).

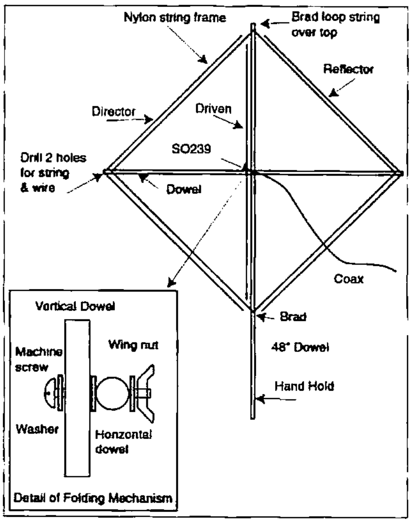

Fig. 1. Construction details for the 2 meter diamond beam.

After modifying the diamond design for 2 meters and switching to vertical polarization, I built a satisfactory three-element portable VHF beam. The entire contraption weighs little more than my Kenwood hand-held rig and is designed to fold into an easily transportable four-foot-long shape. I would not necessarily use it as a walking stick, but it is similar in size.

My intent was to build a 2m beam that could be used while hilltopping, traveling, or for emergencies. The beam must be light, easy to transport, and as compact as possible when not in use. Most importantly, construction has to be inexpensive. Moreover, three elements seemed to be the smallest design that would be of any real practical use.

Construction

By selecting 5/8-inch diameter wooden dowels for the frame and insulated wire for the elements, I was able to accommodate all of the basic requirements. Actual construction entailed the following steps:

1. Rough-cut a 38-inch long dipole, to be tuned to the center operating frequency desired by means of an SWR meter.

2. Tape the dipole to the top of a 48-inch dowel and carefully trim the ends until a 1:1 SWR is achieved. After finding the correct length, use a wood screw to fasten the SO-239 connector to the dowel. Use tape to hold the dipole against the wood.

3. Measure the length of the dipole and cut a director (95% of driven element) and a reflector (105% of driven element).

4. Cut a second dowel 2 inches longer than the driven element and mount it perpendicular to the vertical support using a machine screw, washers, and a wing nut. This arrangement allows the frame to be folded when not in use. Small brads are used at the top and bottom of the vertical dowel to hold the string framework in place. By making the horizontal brace 1/2 wavelength, the element spacing is 1/4 wavelength at the centers and the diamond shape is achieved.

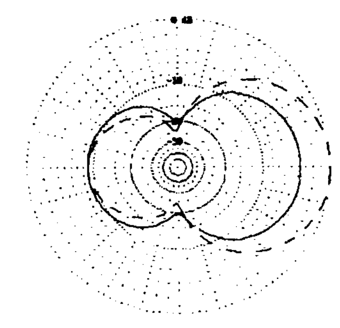

Fig. 2. Comparison of a traditionally-shaped commercial (MFJ three-element portable) antenna and the 2m diamond beam, using Eznec software.

"The beam is light, easy to transport, compact when not in use, and, most importantly, inexpensive to build."

5. Using nylon string, fasten the director and reflector into place, and use a spring-loaded clothespin for coax strain relief. When folded for transport, the top and bottom string supports are released from the brad. The wing nut permits quick tension relief for folding.

6. The final assembly step is to recheck the SWR; some additional trimming of the driven element will probably be necessary to overcome the effects of the parasitic elements. Cut the dipole in very small equal increments at both ends for best results.

Refer to **Fig. 1** for basic construction details. All components should be available at either Radio Shack™ or your local hardware store. I have been using a 40-inch piece of RG-8x to connect the antenna to my 2m rig. I used a Radio Shack 2m SWR meter to obtain the lowest possible SWR.

Testing

After completing the construction, I made some simple tests of the antenna and raised all the area repeaters without difficulty. More interesting was the fact that there were new simplex frequencies open for me to explore. I monitored the 147.21 repeater from Maine (which is often heard in the Boston area) and found that by turning the beam from side to side, I could change reception from 100% copy to inaudible, indicating reasonably good directivity.

I used Roy Lewellan's latest antenna software (Eznec) to compare the diamond antenna to a traditionally-shaped commercial beam. The results show that the diamond shape antenna is a perfectly viable alternative. I measured my MFJ three-element portable beam and loaded the element sizes into Eznec. I did the same for the diamond beam and compared the patterns of each (**Fig. 2**). Not surprisingly, the MFJ antenna has a sharper pattern to the sides and a better front-to-back ratio, but the diamond beam does surprisingly well for a package that weighs and costs only a fraction of the amount of a commercial antenna.

In conclusion, anyone in need of a simple 2m beam should review the available ham literature and decide if the diamond beam fits the bill. Read the original article by G4ZU in the *Antenna Compendium Volume 2*. At the end of the process, you will be hard pressed to find a simpler compromise antenna design than the diamond shape.

Oersted...Faraday...Tesla

Their discoveries created our worldwide system of electric power.

John W. Wagner W8AHB
3890 Tubbs Road
Ann Arbor MI 48103

The discoveries made by these three Giants of Electricity, perhaps more than any other scientific breakthrough since 1888, are responsible for advancing mankind as no other discovery has since Johannes Gutenberg invented the movable type printing press in 1453.

The early experimenters

Focusing on three is probably unfair to many others who also made significant contributions in electrical science. André-Marie Ampère (1775-1836), a mathematician, and Georg Simon Ohm (1788-1854), a schoolteacher, made truly significant contributions establishing the science of electrodynamics and electrical conduction, respectively. The properties of electromotive force in Ampère's time were in a constant state of interpretation and revision by many investigators; however, it was Ampère's brilliant deduction that solved the scientific riddle. Between 1820 and 1823, Ampère experimented with current-carrying conductors and reasoned that electromotive force is manifested by two kinds of effects: electric tension and electric current; thus, he established the concepts of voltage and current. Three years later Ohm defined the exact relationship between these two entities. Today, Ohm's Law remains the most basic and universally used of all laws in electrical science.

There were many others who made advancements, too numerous to mention in this short account; however, the names of Joseph Henry (1797-1878), James Clerk Maxwell (1831-1879), and Heinrich Hertz (1857-1894) stand out prominently. Henry, an American physicist experimenting with electromagnets in 1831, discovered *self-inductance*, a separate phenomenon of electromagnetic induction. Maxwell, a Scottish mathematical genius, established the laws of *electrodynamics* by formulating four fundamental equations defining the electromagnetic theory. He concluded that energy could be transmitted by electromagnetic waves at the speed of light. Hertz was convinced that Maxwell's mathematical postulates were correct, so he set out to interpret and prove Maxwell's work through experimentation. The experiments proved those postulates—that electromagnetic waves were indeed propagated in air at the speed of light.

In most long and arduous journeys into the unknown, interim breakthroughs are reached before the ultimate goal is achieved. The journeys traveled by Oersted, Faraday, and Tesla clearly illustrate this reality. In short, these men made those pivotal breakthroughs in electrical research that resulted in our worldwide system of electric power.

"*Without realizing it, Oersted had discovered the magic doorway that would ultimately lead to the age of electricity.*"

One thing is certain: The single characteristic most great scientists share is *insatiable curiosity*. Perhaps more often than not, luck plays an important role and a great discovery is made accidentally when the curiosity seeker simply stumbles upon an eternal principle—often try not to split doing so without realizing the significance of his discovery.

Thales of Miletus was one of the "seven wise men" of ancient Greece who lived some 2,500 years ago. In his search for the substance from which everything in nature is made, he accidentally discovered static electricity by rubbing a piece of amber with cloth, resulting in the amber attracting bits of feathers and the pith of plants. The discovery of the lodestone's magnetic attraction is another example of early "curiosities in nature" that ultimately led to present-day knowledge...a world these early curiosity seekers could not possibly envision.

It was not until many hundreds of years later that the next truly significant advancement was made. In 1453, Johannes Gutenberg changed civilization forever with his movable type printing press, a significant factor in the beginning of the Renaissance period that swept through Europe. The Renaissance is characterized as a rebirth in all forms of learning, including a revival of interest in the wisdom of the ancient world of the Near East and Greece. Two names from that period stand out as beacons lighting the way for others to follow: Galileo Galilei (1564-1642), an Italian; and William Gilbert (1544-1603), an English physician. They were the first to reject ancient thinking, which for hundreds of years had dominated man's knowledge of his world. Galileo is called the founder of modern experimental science. It was his bold defiance of ancient teachings that established the beginnings of the scientific method. He made his own telescopes, the largest available, and gathered much new information about the moon, stars, and planets. In addition, his experiments with the pendulum and falling bodies changed forever previously held beliefs adding greatly to the understanding of physics. In England, Gilbert's scientific study of the magnet culminated in a monumental

treatise entitled *De Magnete*. His quest was to improve the accuracy of the magnetic compass for better navigation on the seas and oceans. What he never realized was that he also laid the foundation of magnetic science, a key element that eventually led to the generation of electricity.

Pioneers in the age of electrostatics

Gradually, scientific investigators entered a period dominated by the study of electrostatics which was thought of as a curious phenomenon of nature with little or no practical value. The major thrust of scientific investigation during this period, as far back as Gilbert, still centered on improving the magnetic compass, although many independent investigators were working on the properties of conductivity. Charles A. Coulomb (1726-1806) was most prominent during this era because he established the fundamental laws of static electricity, and later made significant advancements in the manufacture of compass needles. Investigators became proficient at generating and instantly discharging static electricity, but they had no way of storing it. E. G. von Kleist and Pieter van Musschenbroeck bridged that gap in the early 18th century with their invention of the Leyden Jar, a capacitive device that could store static electricity for discharge later. It became a novelty item for royalty who took pleasure in shocking unsuspecting victims. It was all in good fun, but there was still no hint of where electrical investigation would eventually take mankind.

Then, in 1800, Alessandro Volta (1745-1827) made the first electrochemical cell and battery capable of producing continuous electric current. His inspiration came from Luigi Galvani (1737-1798), a physician who had been conducting experiments with frog legs hung on brass hooks. The legs convulsed when he touched a piece of iron to the framework. Galvani proposed a theory of "animal electricity" as the reason the frog legs had muscle spasms. Volta disproved this theory, stating accurately that the frog legs convulsed as a result of their being in contact with two different metals. His metal theory intrigued him, so he conducted numerous experiments. Eventually, Volta created a chemical cell capable of producing a continuous electric current. He assembled zinc disks alternately with silver disks, separated by pasteboard soaked in brine solution, and called it an "electric pile." No longer was static electricity the only form of electricity known to man; Volta's continuous current cell was indeed a milestone in the annals of discovery. It was Volta's chemical cell that truly put electricity on the move, and today the battery is still an important, although minor, source of electrical energy.

Michael Faraday worked diligently toward his goal until he achieved it. If Oersted discovered the magic doorway that would lead to the age of electric power, it was Faraday who unlocked that door. His public wondered what use could possibly come from producing a small current by moving a magnet near a length of wire...the Genie still needed to be tamed to become man's tireless servant. Faraday understood the far-reaching possibilities and is said to have replied, "What is the use of a new-born baby?" Further example of Faraday's wit has become English folklore. The Prime Minister is said to have asked him what use could be made of his discoveries. Faraday allegedly responded, "Someday it might be possible to tax them."

"More often than not, luck plays an important role and a great discovery is made accidentally when the curiosity seeker simply stumbles upon an eternal principle."

Oersted

The next exciting event took place in 1820, in the classroom of a Danish professor named Hans Christian Oersted (1777-1851). He was conducting an experiment with one of his students, showing him how a wire could be heated when it is connected to a voltaic pile. Oersted had neglected to clear the table after his previous experiment, and a magnetic compass remained near the wire. When the connection was made to the voltaic pile, the compass needle turned and pointed toward the wire. At first, Oersted could not believe what he had seen, but ultimately he realized he had discovered something new: Electricity and magnetism were interrelated. He named this new force in nature *electromagnetism*. Without realizing it, Oersted had discovered the magic doorway that would ultimately lead to the age of electricity.

Michael Faraday

Michael Faraday (1791-1867) made the next giant step on the long road leading to modern-day electric power. The impetus that set him on his series of epoch-marking experiments was news of Oersted's discovery of electromagnetism. Faraday reasoned that if electricity produces magnetism, then why shouldn't magnetism produce electricity? Finally, in 1831, his experiments revealed a great truth: Electricity could indeed be produced by magnetism; however, the critical component of his discovery was that magnetism must be accompanied by motion. Unlike Oersted, who accidentally stumbled upon his discovery of electromagnetism,

For the next 51 years, man struggled to increase the electrical output of Faraday's embryonic generator. His genius had shown the way; now it was up to engineers to make progressive refinements of his discovery. Volta's batteries had been used initially for electroplating metals, but they were large and very expensive. Gradually, engineering advancements in magneto-electric generators surfaced. Besides their use in the electroplating industry, these first generators were also used for powering arc lamps, lighthouses, and naval vessels. Arc lamps required DC, so a commutator was necessary for rectifying naturally-occurring AC. By 1872 the DC generator had reached its peak of refinement, and DC motors had also come into limited use, but they proved to be inefficient and troublesome, creating sparks and requiring frequent maintenance. In addition, DC power was inherently inferior due to its I^2R voltage loss, and could not be sent a distance greater than half a mile from the generating station. DC also required inordinately large cables to transmit the current, making it very expensive. Nevertheless, this was the only path man knew to follow.

In 1880, the Menlo Park group, headed by Thomas Edison, invented the first practical incandescent lamp, which was a much needed improvement over

the power-hungry and dangerous arc lamp. Edison, whose thirst for entrepreneurial conquests exceeded (or perhaps equaled) his popularity as an inventor, saw the opportunity to capitalize on the new incandescent lamp by using existing DC technology as a power source. He attracted investors to fund the construction of a power station in New York, and soon more DC power stations were built in America and abroad. Their existence proved to be a short–lived evolutionary trend, doomed to extinction due to their inherent inefficiency. DC power, even in its refined state, barely cracked the door to the awesome power contained in Faraday's Genie.

Tesla

Harnessing alternating current was deemed impossible by leading authorities, including the physics professor of a young engineering student in Austria named Nikola Tesla. His idea was the exact opposite of his professor's, and he set out to prove that AC could indeed be harnessed. Professor Poeschl and his classmates laughed at him, but he was undaunted. For two years Tesla went into a state of self-imposed exile, devoting his entire energy to solving the AC conundrum. He sensed that the answer was hidden in his mind and would eventually come forth, but the mental anguish he suffered during his search nearly killed him, so strong was his resolve. Then, in 1882, the solution came suddenly, in a blinding flash, as he recited poetry while walking in a park. In that instant, his brilliant mind conceived perhaps the most beautiful and ingenious scientific creation since the invention of the wheel. In a sense, it was very much like the wheel; he called it the *rotating magnetic field.*

"In that instant, Tesla's brilliant mind conceived perhaps the most beautiful creation since the wheel; he called it the rotating magnetic field."

Tesla's understanding of the awesome power contained in Faraday's Genie was clearer than any of his contemporaries could imagine. The problem of how to harness that energy to do the work of giants had dogged him for more than two years, and now he had discovered the final solution to make alternating current man's servant! The scientific community had always regarded AC as equal to a perpetual motion concept—utterly ridiculous! During Tesla's sudden burst of brilliance on that day in the park, he not only conceived the rotating magnetic field but an entire system of *polyphase AC* that has remained unchanged in principle to this day. Energy in the form of electric power could now be used in virtually unlimited amounts anywhere. His rotating magnetic field discovery, equal in importance to Oersted's and Faraday's pioneering achievements, is a principle of unfathomable beauty that will live forever. It stands today as the foundation on which our entire world operates. Indeed, the power of Faraday's Genie, captured by Tesla, was, and still is, the most important scientific discovery in more than 500 years. Tesla had not only opened Faraday's magic door, his polyphase system literally blew it off its hinges and took the entire wall with it.

Today, the world owes Oersted, Faraday, and Tesla a tremendous debt of gratitude, for it was their monumental discoveries in electrical science that gave us the power to run our factories, mills, schools, hospitals, research centers, stores, and homes.

Technological advances are happening at an ever increasing rate, and we seem always to be looking forward—which is good, but would it not also be uplifting to look back and acknowledge, even pay homage, to the pioneering spirit of those whose efforts laid the foundation for all the technological advantages we enjoy today? Our schoolbooks, teachers, and professors seldom mention these pioneers (if indeed they know anything of their existence). Further, many historians and book writers have elevated the names of entrepreneurs and technologists, crediting them with discoveries made by early pioneers, and if we are not more mindful, our historical heritage will be lost forever. 73

NEVER SAY DIE

Continued from page 29

One ham suggested a way to solve the deficit problem would be to fire the top three layers of management of all federal bureaus on the basis that it's unlikely that anyone lower down would notice much difference. Oh, the bureau's jet planes would get less use. But why not fire 'em down five levels and start reducing the deficit instead of just stopping its growth?

Oh yes, one more innovation. Since many of our more serious social problems have been caused by federal judges running amok, bypassing the legislative system, how about putting term limits on those rascals too?

Bioenergizer Update

Bob Beck called with some suggestions for researchers working with doctors toward the elimination of crud in the blood, as described in the lead article in May. Firstly, don't use any metal in contact with the skin, since even low levels of current can cause burns. Bob recommends that the electrodes be made of heavy wire cut one inch long, or perhaps a nail, wrapped with flannel. The flannel can be held in place with heavy thread. Then you soak the flannel in a saline solution to provide conductivity.

In my experience, if you don't get the electrodes exactly over the wrist veins and in line with them, you can still get some slight burns. They don't hurt, just itch. You can feel the throbbing when the electrodes are exactly in place. I use a 1-inch wide strip of elastic with hook-and-loop fastener on the ends to hold the electrodes in place on my wrist, and a second an inch farther up the arm to keep the wires from yanking the electrodes out while I'm working or typing.

Bob also recommends the use of a 100k pot instead of 1 meg to give better control of the voltage. And he says not to use more than three 9V batteries (27V). Though there have been no reported problems with heart pacers, there is the potential for such trouble, so the best bet for doctors researching this field would be to avoid pacer patients until more is known.
